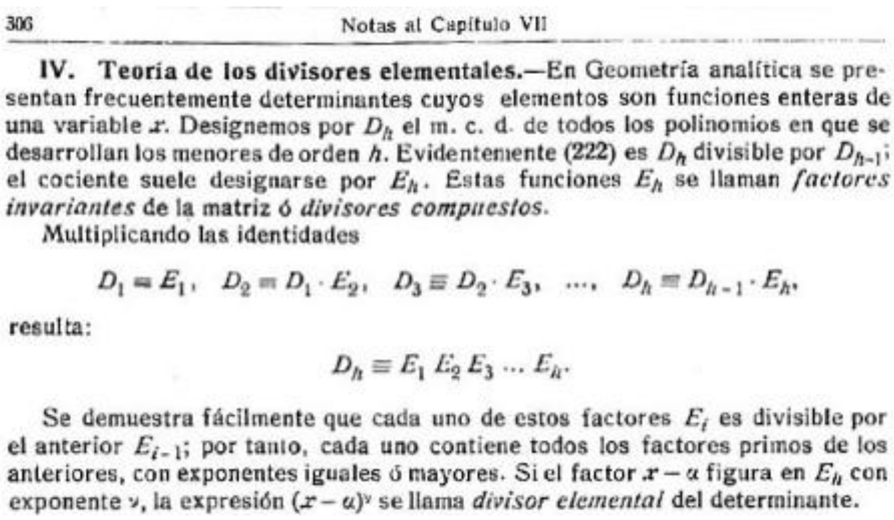
- S. Cámara on the geometric theory of cyclical lines of the fourth-order and first type [9], as spherical curves analytically studied by Darboux.
- J. Rey Pastor on "algebraic" curves defined by correspondences [27] following Cremona's synthetic methods.
- O. Fernández-Baños on complex n-dimensional synthetic geometry [18] following the axiomatic approach of projective geometry that Julio Rey Pastor developed during his stay in Göttingen.

Julio Rey Pastor began his academical work as a geometer, but he became a professor of Mathematical Analysis at the University of Oviedo and a later at the University of Madrid. He published his lecture notes titled *Resumen de las lecciones de análisis matemático (primer curso)*, 1914-15, and *Resumen de las lecciones de análisis matemático (segundo curso)*, 1915-16. From these early drafts, he published three well-known textbooks, [17]. The first one (1917) was *Elementos de análisis algebraico*, [29], wherein the author introduces a new orientation[7] for 1st and 2nd Mathematical Analysis subjects in Spain.

The book is comprised of 4 parts, each dealing with the operations and properties of a number system, and containing the mathematical theory belonging to it. The four parts are devoted to the natural, rational, real and complex numbers, respectively. The "algebra" and its finite algorithms are considered in the first and second parts, and the "analysis" and its unlimited algorithms based on the notion of limit, in the third and fourth. The "specific theory" of the rational numbers talks about the algorithms dealing with progressions, continued fractions (finite and periodicals) or determinants, and the "algebraic algorithm" (study of polynomials of several variables and its divisibility) to which Chapter VII is devoted. Merely as an endnote to this chapter, Rey Pastor includes a brief reference to elementary divisors in their algorithmic formulation, in terms of data related to certain determinants. In the following paragraph the whole text of the note is reproduced.

> **IV. Elementary divisors theory.—** In analytical geometry there are often determinants whose elements are entire functions of one variable x. We denote by D_h the g.c.d of all polynomials where the minors of rank h develop. Obviously (222) D_h is divisible by D_{h-1}; the quotient is usually denoted by E_h. These functions E_h are named invariant factors of the matrix or composite divisors. Multiplying the identities
>
> $$D_1 \equiv E_1,\ \ D_2 \equiv D_1 \cdot E_2,\ \ D_3 \equiv D_2 \cdot E_3,\ \cdots,\ \ D_h \equiv D_{h-1} \cdot E_h,$$
>
> it follows
>
> $$D_h \equiv E_1 E_2 E_3 \cdots E_h.$$
>
> We can easily show that each of these factors E_i is divisible by the previous one E_{i-1}; therefore, each one contains all the prime factors of the previous ones, with equal or greater exponents. If the factor $x-\alpha$ appears in E_h with exponent v, the expression $(x-\alpha)^v$ is named elementary divisor of the determinant.



306 Notas al Capítulo VII

IV. Teoría de los divisores elementales.—En Geometría analítica se presentan frecuentemente determinantes cuyos elementos son funciones enteras de una variable x. Designemos por D_h el m. c. d. de todos los polinomios en que se desarrollan los menores de orden h. Evidentemente (222) es D_h divisible por D_{h-1}; el cociente suele designarse por E_h. Estas funciones E_h se llaman *factores invariantes* de la matriz ó *divisores compuestos*.

Multiplicando las identidades

$$D_1 \equiv E_1,\quad D_2 \equiv D_1 \cdot E_2,\quad D_3 \equiv D_2 \cdot E_3,\quad \ldots,\quad D_h \equiv D_{h-1} \cdot E_h,$$

resulta:

$$D_h \equiv E_1 E_2 E_3 \ldots E_h.$$

Se demuestra fácilmente que cada uno de estos factores E_i es divisible por el anterior E_{i-1}; por tanto, cada uno contiene todos los factores primos de los anteriores, con exponentes iguales ó mayores. Si el factor $x-\alpha$ figura en E_h con exponente ν, la expresión $(x-\alpha)^\nu$ se llama *divisor elemental* del determinante.

It is remarkable that Rey Pastor gives the above definition accompanied with the following comment, [29, p. 306]:

---

[7] This book was inspired by the book of algebraic analysis [1] by Alfredo Capelli (1855-1910).

> In parallel to the theory of these algebraic elementary divisors, the theory of numerical elementary divisors can be developed in the same way, based on a determinant whose elements are integers, and applying the numerical divisibility rather than the algebraic. The nature of this work does not allow covering either of these two interesting theories.

Among the books that Rey Pastor recommends for this chapter we find Böcher's widely-read 1907 algebra text [5] which deals with this topic.

The period 1918-1936

A first sketch of elementary divisors theory is due to a pair of professors who developed a mathematical project with their young colleague Rey Pastor: Sixto Cámara Tecedor (1878-1964), [13], and Olegario Fernández-Baños (1886-1946), [24].

1. Fernández-Baños' research

When Fernández-Baños finished his doctorate he obtained a grant from JAE to study abroad. He worked with the geometer F. Enriques (1871-1946) at Bologna (Italy). When he finished the stay he presented a report to the JAE on the work, which contained two papers, the second of which was *Contribution to the study of networks of homographies that contain the identity of E_n. Generalization of Weierstrass' theorem*, referred to the elementary divisors, [19]. The article was dated Bologna, 15th December, 1917, and published in Madrid a year later.

Weierstrass considered the general problem of determining the necessary and sufficient condition under which one pair of bilinear forms P and Q can be transformed into another pair P' and Q' by means of non-singular linear transformations. The condition is that both determinants $| pP + qQ |$ and $| pP' + qQ' |$ have the same elementary divisors [32], being Weierstrass' completely algebraic treatment.

The aim of Fernández's paper was the generalization of Weierstrass' theorem of triples (I, P, Q) instead of pairs, where I is the identity. Once the problem was established, Fernández-Baños, according to the geometric training received in Spain, left the algebraic route to follow the "geometric translation" of Weierstrass' theory given by Segre, according to which, "a general homograph is perfect and uniquely determined by its *fundamentals spaces* and *absolute invariants*" [19, p. 233]. This path had already been established by Bonola[8] in spaces E_2 and E_3, characterizing in E_2 a network (I, P, Q) of homographies by means of a cubic curve C and an involution g in it, with a similar version for E_3. The work of Fernández-Baños, newly making good use of his doctoral thesis, consisted of extending Bonola's results to space E_n of arbitrary finite dimension, so that he was obliged to modify the procedure of his Italian predecessor. The general result of Fernández-Baños is that "the necessary and sufficient condition such that a couple of networks of general homographies in E_n, that contain the identity, to be projectively identical is that they have the same line of double elements, and the same involution in it, that is, the same pair (C, g)" [19, p. 245]. The author finished his paper uniting the modernizing spirit that impelled the JAE, affirming the end of his paper, "hoping that the processes that we have employed acquire some development in our homeland, at least to contribute some progress to modern algebraic geometry", [19, p. 249].

Nevertheless, Fernández was dedicated himself to other things later. Therefore, there was no need to continue researching in that direction and he became a professor of Analytical Geometry at the University of Santiago de Compostela in 1921, an isolated university on the periphery of research. In 1923 he obtained a grant to study Mathematical Economics and Financial Economics in France and Italy. His research focused on Economic Statistics thereafter. In 1928, he obtained another grant from University of Santiago de Compostela[9] to study Applications of Mathematics towards Statistics and Economics in Switzerland and Italy. In 1930 he was designated deputy head of Economical and Financial Studies at the Banco de España. Finally, in 1933 he became a professor of Mathematical Statistics at the Central University of Madrid.

2. Cámara's teaching

S. Cámara became a professor of Analytical Geometry in 1917 at the University of Valencia, where in 1920 he published the first part of his textbook [10], devoted to plane geometry. Influenced by Rey Pastor, Cámara follows Felix Klein's Erlangen Program, where geometry is characterized by transformations. In his words [10, Preface]:

> The professor Julio Rey Pastor has indicated the milestones that should be a guide for the mathematical progress of our homeland; in these milestones we have been inspired to write this book; fruit of the ambience of the mathematical seminar adviser of our studies towards the high questions of current mathematics. […] located from the point of view of Klein and Rey Pastor we have inspired a new work in the great syntheses of the groups of geometric transformations, whose

[8] R. Bonola (1874-1911). See [6, Nota 2ª].

[9] In this University he obtained a degree in Law.

> invariant properties characterize the geometry of the group. It is clear that by the elemental nature and pursued object in the book we have merely referred ourselves to linear transformations and quadratic curves.

This textbook is remarkable for the use of matrices in the study of geometry. Thus, Cámara included in this text several indications about linear transformations and group theory; Weierstrass' elementary divisor theory was also referenced in order to classify collineations and quadratic curves.

Cámara studies collineations in the 3rd chapter, titled "Line and point" dealing with the two dual notions. There he considers the characteristic matrix, and the roots of the characteristic equation which determine fixed points and lines; according to the number and the incidence relations between these invariants, different types of collineations are obtained (homologies, etc.).

$$\begin{bmatrix} a_{11}-\rho & a_{12} & a_{13} \\ a_{21} & a_{22}-\rho & a_{23} \\ a_{31} & a_{32} & a_{33}-\rho \end{bmatrix}$$

At the end of the chapter, there are six pages of "Notes" in small characters, where Cámara explains that the "Weierstrass' elementary divisors" of the characteristic matrix are enough to classify collineations, because they determine "double elements; their relative position; the absolute invariants of the collineation, and its canonical equations", (see table 2, [10, p.158]). For information about elementary divisors Cámara refers to the short note in [29] (Cámara wrote: "See Rey Pastor, *E. de A. A.* , page 306"), and his explanation is also very brief, only a sketch to encourage further study.

Table 2.

Exponentes de los divisores elementales de Weierstras	Orden de multiplicidad de las raices: 1 1 1	2 1	3
1 1 1	$(\rho-\rho_1)(\rho-\rho_2)(\rho-\rho_3)=0$ Un triángulo de elementos dobles; dos vértices, y los lados o, uestos, pueden ser imaginarios conjs.	$(\rho-\rho_1)(\rho-\rho_1)(\rho-\rho_2)=0$ Homología con centro exterior al eje.	$(\rho-\rho_1)(\rho-\rho_1)(\rho-\rho_1)=0$ Coincidencia de los dos planos; todos sus elementos son dobles
2 1		$(\rho-\rho_1)^2\ (\rho-\rho_2)=0$ Un punto y una recta dobles, incidentes; y otro punto y otra recta dobles, no incidentes.	$(\rho-\rho_1)^2\ (\rho-\rho_1)=0$ Homologia con el centro en el eje.
3			$(\rho-\rho_1)^3=0$ Un sólo punto y una sola recta dobles, incidentes.

In the 5th chapter, "Elements of the general theory of conics", the author also shows that the elementary divisors of the matrix

$$\begin{bmatrix} A+\lambda A' & H+\lambda H' & G+\lambda G' \\ H+\lambda H' & B+\lambda B' & F+\lambda F' \\ G+\lambda G' & F+\lambda F' & C+\lambda C' \end{bmatrix}$$

are enough to determine the relative position of two conics, and he gives a similar table [10, p.380].

At that time, Cámara taught in the Science Faculty of the University of Valencia, where the Exact Science degree course was not offered, Cámara's students were chemists, to which an in-depth treatment of these topics were not adequate. During his stay in Valencia, Cámara studied and published on probability and statistics, with an interest in its applications to mechanics, and in 1933 he competed with Fernández-Baños for the Chair of Mathematical Statistics at the Central University. Two years later Cámara moved to the Central University of Madrid, where he got the chair that had long belonged to Vegas. However, during 1936-1939 the Spanish Civil War took place; due to this social upheaval, research and teaching were seriously interrupted.

After the Civil War

After the war, Cámara restarted his activity as professor of Analytical Geometry at the Central University of Madrid. The final period of his academic activity lasted until his retirement in 1948. The second edition of Cámara's book [11] appeared in 1941, and the third [12] in 1945, including modifications due to the suggestions of Álvarez Ude.[10] The book was intended for students of Exact Science, and the first edition was clearly improved in content, theoretical explanations and applications. In the third edition, Cámara added two chapters devoted to Euclidean transformations and a smattering of other algebraic concepts: fields, rings, isomorphisms, notions of tensor algebra and matrix theory. However, Cámara did not undertake the unified treatment of the geometry in arbitrary finite dimension.

At that time he lectured on n-dimensional geometry, but the book continued to be divided in plane and space geometry, like twenty years before. This produced some repetitions that he was trying to avoid. For instance, the elementary divisors that had appeared in the first edition in plane geometry, are not considered in dimension two, but in the geometry of the tridimensional space. There, in the section of complementary notes, he incorporated an explanation of the n-dimensional elementary divisor theory, this was much more thorough than that of 1921, but yet without proofs. Cámara referred to [5] and [31] to study the complete theory.

In order to explain completely the elementary divisor theory, more algebraic subjects were needed, but the official syllabus remained unchanged until the reform of 1944. Then the old *Exact Science* was renamed as *Mathematics* and its syllabus enlarged to five years. The projective geometry course evolved from synthetic to algebraic geometry in the new subject "Geometry 3rd", where the abstract linear algebra and the elementary divisor theory came to find its location. The new image of algebra and modern geometry arrived to Spain, but this task was not done by Cámara, but rather by the younger mathematicians. Cámara re-edited his book in 1963, with the incorporation of suggestions due to "some professors of Technical Higher Schools"; this fact indicated that the use of his book had been shifted to a more practical teaching, because of its numerous exercises and examples of applications to physics.

Since before the Civil War, Tomás Rodríguez Bachiller (1899-1980) furthered the development of new abstract mathematics, algebra and topology.[11] The reception process of abstract linear algebra and its applications to geometry was completed by the first postwar doctoral students. Among them,[12] the final step was given by Abellanas,[13] who in 1942 studied with the algebraist B. L. Van der Waerden in Leipzig, thanks to a grant from the Fundación Conde de Cartagena. In the same year, Abellanas became a professor of Analytical Geometry and Topology at the University of Zaragoza. Then, he was a professor of Projective Geometry at the University of Madrid from 1949 onwards.

In 1961 Abellanas published the textbook *Geometría Básica* [3], with four chapters devoted to abstract (over an arbitrary field) n-dimensional linear algebra and geometry (pp. 1-388), and four more chapters on elementary differential geometry of curves and surfaces (pp. 389–562). Now we are interested only in the first part of the book: Chapter 1, The vector space; Chapter 2, The affine space and the Euclidean space; Chapter 3, The projective space; Chapter 4, Affine and Euclidean spaces as subspaces of the projective space. In each case, mappings among the corresponding spaces are studied. The first chapter include §8. *Structure of the endomorphisms of the vector space,*[14] which deals with elementary divisors for matrices of polynomials.[15] The third chapter concerns the applications of elementary divisors to classify

---

[10] J.G. Álvarez Ude (1876-1958) was Cámara's professor of Descriptive Geometry at the University of Zaragoza. He moved then to Madrid when Torroja retired in 1916.

[11] See [16] and L. Espanol, Mª A. Martínez. *The biography of the Spanish mathematician Tomás Rodríguez Bachiller (1899-1980)* in these Proceedings of the 4th ICESHS.

[12] In the early forties, Francisco Botella (1915-1987) published two elementary papers following Cámara's lectures [7, 8].

[13] Pedro Abellanas (1914-1999) prepared his doctoral thesis on differential geometry under the adviser Tomás Rodríguez Bachiller in 1941 [26].

[14] The book presents a typo, it says automorphisms where it should say endomorphisms, as we have written.

[15] In 1958, Abellanas had published the first edition of a textbook, *Elementos de Matemáticas* [2], on linear algebra and calculus, addressed to first year students. In the fourth edition (1965) the classification of finitely generated abelian groups was included. But the

collineations and pencils of quadratic forms. Abellanas' books [2, 3] make no reference to Spanish or foreign authors, they were as self-sufficient as Franco's Spain, of which the author was a supporter, and the study of these books was required in Madrid and other Spanish universities for more than a decade.

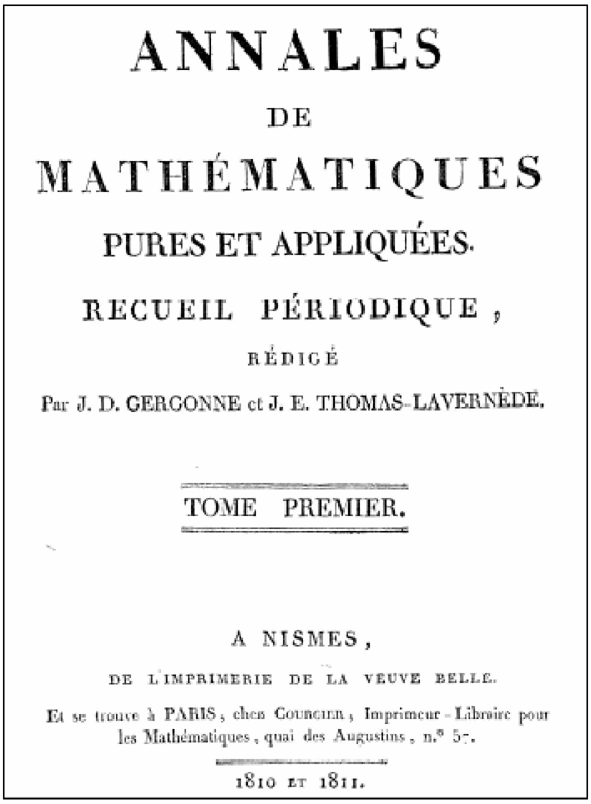
GHDSO – Groupe d'Histoire et de Diffusion des Sciences d'Orsay,
Université Paris Sud 11 – Orsay, FRANCE
gerini@univ-tln.fr; http://christian-gerini.univ-tln.fr

Abstract

We commemorate in 2010 the bicentenary of the edition of the journal of mathematics, the Annales de Mathématiques Pures et Appliquées *de Joseph-Diez Gergonne (22 vol., 1810-1832). This journal profoundly modified the ways of circulation and of diffusion of this science. The initiative of Gergonne quickly involved many mathematicians all over Europe in this new form of communication. But this French initiative also incited Germany and neighbouring countries of France to publish journals specifically devoted to mathematics:* Journal de Crelle *(since 1826),* Annali di Matematica *(since 1858), etc. We can also thus measure in which way a kind of modernity and of specialization had emerged in the mathematics thanks to those journals. And we will try to demonstrate in our introduction that the Annals of Gergonne really were the first modern journal in history devoted to mathematics.*

Warning: this paper is the result of a quick talk that we gave in introduction of our symposium in Barcelona (4th ICESHS, November, 2010) devoted to: "2010, the bicentenary of the Annals of Mathematics of Gergonne: the emergence of the European Journals of Mathematics in the 19th century and their role in the dissemination and the progress of this science". So we apologize if our readers find it too short and would have expected more details.

During the 19th century, Mathematics benefited in Europe from a new form of communication that radically changed exchanges amongst mathematicians of all grades and of many countries: the regular specialized periodicals specifically dedicated to this science. These journals have helped the specialization of this science in an age of rapid technological and scientific developments. In 1810, the French mathematician Jospeh-Diez Gergonne published the *Annales de mathématiques pures et appliquées* (currently called the *Annales de Gergonne*), the first notable monthly journal of mathematics published on the continent. So we celebrate in year 2010 the bicentenary of this important journal of the history of European science.



ANNALES
DE
MATHÉMATIQUES
PURES ET APPLIQUÉES.
RECUEIL PÉRIODIQUE,
RÉDIGÉ
Par J. D. GERGONNE et J. E. THOMAS-LAVERNÈDE.

TOME PREMIER.

A NISMES,
DE L'IMPRIMERIE DE LA VEUVE BELLE.
Et se trouve à PARIS, chez COURCIER, Imprimeur-Libraire pour les Mathématiques, quai des Augustins, n.° 57.
1810 ET 1811.

This paper is a short presentation of what existed in that matter before the *Annales de Gergonne*. We will not develop the topics of the *Annales* themselves but consider the attempts of periodic publications that preceded the *Annales*, in order to prove that they were the first international and regular journal introducing a kind of modernity in the communication between mathematicians. We will give in our conclusion an overview of the initiatives the *Annales* provoked in France and in Europe, from Crelle's *Journal für die reine und angewandte Mathematik* (1826) to Liouville's *Journal de Mathématiques Pures et Appliquées* ("*Journal de Liouville*", 1836) and the *Nouvelles annales* of Terquem and Gerono (1842).

The *Annales de Gergonne* and the mathematics of their time

The *Annales de Gergonne* were published monthly from 1810 to 1832. At the request of Napoleon, Jean Baptiste Delambre wrote in 1808 a report on the state of the mathematics of his time and this document, compared to the contents of the *Annales*, allows us to affirm that those contents effectively dealt with all that was then called "Mathematics" or "Applied Mathematics".

One can see, thanks to the work done by Jean Dhombres in 1989, what made up the mathematics at that time, first in Delambre's classification, secondly in the memories of the first class of the Institute (Academy of Sciences) before 1808[1]:

Geometry / Geodesy and tables / Algebra / Calculus / Analytical mechanics / Astronomy / Geography and travels / Mathematical physics / Mechanics / Manufacture and arts.

If we consider the editorial project of Gergonne (that he gives in the "Propectus", in the first pages of the first issue of his journal), as well as the contents of the *Annales*, we find nearly the same thing:

---

1 Jean DHOMBRES (1989), *Rapport à l'Empereur sur le progrès des sciences, des lettres et des arts depuis 1789 et leur état actuel*, Vol. 1: *Sciences mathématiques*, édition critique du texte de 1810 de Jean-Baptiste Delambre, préface de Denis Woronoff, présentation et notes de Jean Dhombres, Paris: Belin, 1989.

> «Ces Annales seront principalement consacrées aux Mathématiques pures, et surtout aux recherches qui auront pour objet d'en perfectionner et d'en simplifier l'enseignement. Le titre de l'ouvrage annonce assez d'ailleurs que, si l'on n'y doit rien rencontrer d'absolument étranger au Calcul, à la Géométrie et à la Mécanique rationnelle, les rédacteurs sont néanmoins dans l'intention de n'en rien exclure de ce qui pourra donner lieu à des applications de ces diverses branches des sciences exactes.»
>
> Transl: *"The Annals will be mainly devoted to pure mathematics, especially in researches that will aim to refine and simplify their teaching. The book title announces, moreover, that if the journal effectively deals with Calculus, Geometry and rational Mechanics, the editors do not want to preclude any contents that may give rise to Applications of these various branches of sciences".*

For Gergonne, pure mathematics is: arithmetic, algebra, calculus, geometry, and mechanics. And the "applied mathematics" deal with the whole applications of pure mathematics to other sciences (and techniques or arts). And here we find: astronomy, geodesy, optics, gnomonic, catoptrics, etc. He added to his journal all along the 22 years of its edition a discipline called «Philosophy of mathematics»[2].

This allows a distinction a *minimum* among the publications of the second half of the eighteenth century and the first half of the nineteenth century, between those truly interested in mathematics –as they were defined at this period– and those that gave to that mathematics only a secondary or negligible place. We therefore generally examined in our study the periodical publications falling in the first category. The word "periodic" is also too unreliable: there were journals published semi-annually, or annually, but that we can still call "periodic" because they kept the same title and were indexed by successive numbers.

Until 1794: mostly non-French journals

So we can consider among the journals edited in Europe before the *Annales de Gergonne*:

- The *Beyträge zur Aufnahme der theoretischen Mathematik* published in Germany from 1758 to 1761 by W. J. G. Karsten.
- The *Leipziger Magazin für reine und angewandte Mathematik* published quarterly from 1786 to 1788 by Jean Bernoulli and Carl Friedrich Hindenburg.
- The eleven journals of the *Archiv der reinen und angewandten Mathematik* semiannually published by C. F. Hindenburg alone from 1795to 1800.

One can see in it some premises of the ideas that Gergonne succeeded in imposing a decade later with his *Annals*, so that Marteen Bullynck wrote:

> «Les journaux de Hindenburg, enfin, sont les premiers exemples d'un journal spécialisé, forme de communication qui ne s'établirait définitivement qu'au 19ème siècle.»[3]
>
> Transl. *"The Hindenburg's journals, finally, are the first examples of a specialisation in the periodical edition in mathematics that will be definitely established in the nineteenth century".*

We do find in it a real periodicity: Hindenburg first wanted a journal published four times per year and succeeded in maintaining a semi-annually publication. The population of authors is larger, even if they are geographically based in northern Germany. And here we found a new generation of mathematicians and not only those who, until then, shared with Hindenburg the passion of combinatorial analysis and had written a majority of the articles of *Leipziger Magazine*:

> The Archiv did, however, not become a mere vehicle of combinatorial analysis. It included a large variety of contributions and contributors. Not only did the old generation that already wrote for the Magazin (Kästner, Klügel, Hennert) continue to contribute, but also professors, teachers and enthusiasts from the new generation filled the Archiv's pages.[4]

[2] See for example for more details our book: Christian GERINI (2003), *Les Annales de Gergonne. Apport scientifique et épistémologique dans l'histoire des mathématiques*, Villeneuve d'Ascq: éditions du Septentrion.

[3] Marteen BULLYNCK (2011), Stages Towards a German Mathematical Journal (1750-1800), in: Jeanne PEIFFER et Jean-Pierre VITTU (eds.), *Les journaux savants dans l'Europe des XVIIe et XVIIIe siècles. Formes de la communication et agents de la construction des savoirs*, Amsterdam: Brepols, to be published.

[4] *Ibid*.

In England, at the end of the 18th century, the *Leybourn's Mathematical Repository*, published by Thomas Leybourn, Pr. at the Royal Military College of Great Marlow, has also been one of the first journals of mathematics with a durable periodicity. But the authors were specifically English, and not so many, at least during the period which preceded the publication of the *Annales de Gergonne*, as it can be seen from the list of authors of original articles published in Volume III in 1814: Gough, Knight, Cunliffe, Barlow, J. F. W. Herschel, Bransby, White and the baron Maseres. So it was not a journal of large circulation and it was not open to the European mathematical community. In addition, only 14 issues appeared in the first series (1795-1804) and 24 in the second one (1804-1835). It represents on average about one issue per year: it is far from a monthly frequency like that of *Annals de Gergonne*.

We now quickly mention here the journals which, while publishing in their pages some mathematical texts, or rather for most of them texts about mathematics, were overwhelmingly devoted to other information. So did for example the *Journal des savants*, published in France since 1665[5], the *Ladies diary* published in England from 1704 to 1841[6], or the general or popular German periodicals which only published very little information on Mathematics (generally some reading notes) and which were distributed in some small communities: for example the *Göttingische Anzeigen von gelehrten Sachen* (Göttingen, 1753-1801), the *Allgemeine deutsche Bibliothek*, published in Berlin by Friedrich Nicolaï from 1765 to 1796, the *Neue Bibliothek der Schönen Wissenschaften*, (Leipzig, 1765-1806) or the *Allgemeine Literatur-Zeitung* of Bertich published in Yéna from 1785 to 1803[7].

The journals of European academies and universities had a variable periodicity (but were not often published more than once per year). They were focusing on every science and were not widely disseminated: it is the case, for example, of the *Eruditorum Acta* of Leipzig, and of the *Memoirs* of the Berlin Academy.

From 1794 to 1810: the *JEP* and the *Correspondance* of Hachette

In his *Prospectus* (N°1, June 1810), Gergonne stated his intentions and the reasons for the publication of his journal.

Since 1794 and the creation of the Ecole Polytechnique, two journals dealing with sciences –and more specifically with mathematics– had appeared in France: the *Journal de l'Ecole Polytechnique* (that we will note *JEP*), and the *Correspondance sur l'École Polytechnique* of Jean Nicolas Pierre Hachette.

Gergonne tells us:

> «Les Sciences exactes, cultivées aujourd'hui si universellement et avec tant de succès, ne comptent pas encore un seul recueil périodique qui leur soit spécialement consacré».
>
> Transl: *"The exact sciences [mathematics], now so universally and so successfully grown, do not yet have a single periodical journal devoted specifically to them".*

He adds:

> «On ne saurait, en effet, considérer comme tels, le Journal de l'école Polytechnique, non plus que la Correspondance que rédige M. Hachette: recueils très précieux sans doute, mais qui, outre qu'ils ne paraissaient qu'à des époques peu rapprochées, sont consacrés presque uniquement aux travaux d'un seul établissement.»
>
> Transl: *"We can not, in fact, consider as such the Journal of the Ecole Polytechnique, nor the correspondence that Mr. Hachette proposes: valuable journals without doubt, but which, besides the fact that their issues are not published so close from each other, are devoted almost entirely to the work of a single institution."*

---

[5] Successively written «sçavans», «savans» et «savants». Cf. Jeanne PEIFFER & Jean-Pierre VITTU (eds.) (2010), *Les journaux savants dans l'Europe des XVIIe et XVIIIe siècles. Formes de la communication et agents de la construction des savoirs*, Amsterdam: Brepols, to be published.

[6] See for example: Shelley COSTA (2002), "The Ladies Diary: Gender, mathematics, and civil society in earlyeighteenth-century England", in: *The History of Science Society*, 17, pp. 49-73.

[7] Maarten Bullynck showed that one can find in it only about 2% of the articles which are devoted to reports on mathematical writings: Maarten BULLYNCK, «*Les interactions entre Rezensionszeitschriften, périodiques scientifiques et périodiques spécialisés. Le cas des mathématiques dans l'Allemagne des Lumières (1760-1800)*»: http://www.histnet.cnrs.fr/research/periodiques-savants/article.php3?id_article=75, web site of the research program: «Les périodiques savants dans l'Europe des XVIIe et XVIIIe siècles», France, CNRS, with the support of the European Science Foundation.

The studies we made of these two journals (and which will be edited in the next Yearbook for European Culture of Sciences), and other works done on that topic[8], allow us to affirm that:

- First, Gergonne is right about the two assertions he gives in his *Prospectus* about them.
- Secondly, the periodicity of those journals was really irregular and with a poor frequency: only 20 issues of the *JEP* have been published from 1794 to 1831 (so with an average of one every two year), and only 10 issues for the *Correspondance* from 1804 to 1810.
- Third, the *JEP* was in fact reserved to an elite (the professors at the Ecole: Monge, Laplace, Poisson, etc.), and the *Correspondance* didn't deal frequently with mathematics.

Conclusion:

We can therefore hypothesize that, historically, the *Annals de Gergonne* were the first journal solely devoted to mathematics and who possessed the qualities of stability, of a real periodicity with short intervals between two numbers (no interruption in the publication, monthly), of a long duration (twenty-one years of existence) and of an international impact: these *Annales* ushered in the principle of a real international journal in this mathematical field. They participated in an essential way in the entry of mathematics in the specialization and the modernity.

As a proof of our conclusion, one can consider the initiatives the *Annales* provoked in France and in Europe, from Crelle's *Journal für die reine und angewandte Mathematik* (Germany, 1826) and the "*Correspondance*" of Garnier and Quetelet (Belgium, 1826) to the *Journal de Liouville*[9] (France, 1836) and the *Nouvelles annales* of Terquem and Gerono (France, 1842). We find again in them the qualities we noticed about the *Annales*: presence of all the mathematical fields, short intervals between the issues (one month), longevity, texts by mathematicians of all communities – domestic or foreign, pupils and professors of college or universities, academicians–, etc.

MATHEMATICAL JOURNALS IN SPAIN DURING THE NINETEENTH CENTURY AND THE BEGINNING OF THE TWENTIETH CENTURY

Mª del Carmen ESCRIBANO RÓDENAS,
Gabriela M. FERNÁNDEZ BARBERIS
Universidad CEU San Pablo, Madrid, SPAIN
escrod@ceu.es
ferbar@ceu.es

Abstract:

In Spain, the Nineteenth Century, was a very difficult period in general and, in issues related to Mathematics Science, in particular. Generalized opinion in relation with the Spanish backwardness of that period in Mathematics was very important. In the Nineteenth Century Scientific Journalism was very affected by the continuous political changes. It will only appear in Spain through certain figures of scientific importance, whose wishes and efforts will allow that those initiatives are an improvement of the Spanish sensibility towards the scientific means of communication that will be developed in Nineteenth Century Spain.
Prominent Spanish Mathematicians were interested in promoting Mathematics in Spain, and from them emerges the idea of editing Mathematics Journals where it would be possible to publish articles and information in relation with Mathematics, but developed within and outside the country. In this paper we look at the first Mathematics Journals that were published in Spain from the Nineteenth Century, which started, most of the times, by private initiative.
In Spain, the spread of Mathematic Science began its evolution thanks to the appearance of those journals with the collaboration of non-Spanish mathematicians.

Introduction

The scientific Spanish community lives a quite erratic Nineteenth Century, since among other things the political situation in Spain has enough political sways during all the century and the first half of the following, which have necessarily repercussions in the scientific and educational environment. The beginning of the new century is not calm either, as in 1923 General Primo de Rivera gives a coup which turns Spain into a Dictatorship until 1931. In that year, the Second Republic is proclaimed and lasts until the Spanish civil war (1936-1939), after which again a dictatorship is established by General Franco. This continuous change of moderate and progressive political currents in the government, that in some cases happened with only some months of difference, supposes a long list of projects and ideas that do not come to light, as every new government implies a change of the previous governments policies.

Quite the same goes for scientific journalism, which in the 19th century will only appear in Spain through certain scientific characters, whose will and effort allow these initiatives to be an advance of Spanish sensitivity toward the scientific means of communication that will be developed in the 20th-century Spain. In particular, concerning Mathematics, some newspapers or periodicals began to be published, in most cases owing to the impulse of Spanish scientists of international recognition.

The Periodical of the Progresses of Exact, Physical and Natural Sciences could be considered as the first Spanish scientific periodical. This periodical is born as a public expression of the Academy of Sciences in 1850[1]. It was published between 1850 and 1905, with a total of 22 volumes. In 1905 the periodical comes to an end, passing to be called *Periodical of the Royal Academy of Exact, Physical and Natural Sciences*. Each volume consists of three sections. At the beginning, the first two years, it was published as a part of the Bulletin of the Ministry of Trade, Instruction and Works, in charge of which their edition ran. The third year, 1852, it was not published due to financing problems, and from 1853 it is published independently of the mentioned bulletin. Between 1853 and 1868, it is published regularly[2], a number for every month of academic activity (9 numbers per year), and starting from this moment, because of several events, the next volume is published in 1871, and the following volume in 1879, another in 1886 and the last published volume in 1905. In the section of Exact Sciences, most of the articles are by foreign authors.

REVISTA

PROGRESOS DE LAS CIENCIAS

MADRID.

Febrero de 1861.

But looking at our mathematical environment, the first periodical with mathematical character that even takes this word in its title is the *Monthly Newspaper of Mathematical and Physical Sciences*, born in 1848 by wish of the military Sanchez Cerquero, in the Spanish province of Cadis.

The *Monthly Newspaper of Mathematical and Physical Sciences* of Cadis

In the military environment of the Astronomical Observatory of San Fernando in Cadis, in 1848 appears the first specialized periodical in Mathematics and Physics, published by the ex director of the Observatory, the retired Brigadier of the Armada, D. José Sánchez Cerquero.

[1] See Pérez García, M.C. and Muñoz Box, F. (1988): *Estudios sobre historia de la ciencia y de la Técnica: IV Congreso de la Sociedad Española de Historia de las Ciencias y de las Técnicas: Valladolid, 22-27 de Septiembre de 1986*. Págs. 543-552.

[2] Their regular publication does not mean a regular number of pages; these oscillate between 384 pages of the III volume to 576 pages of the XVI volume.

In the first number of this periodical, July 1848, one could read about the intention that each new number appeared on the first day in every month, with a total of 32 pages. In the last number published of December of 1848, a note is inserted where it is said that the editor suspends publication due to the sacrifices that he has had to endure during the six months of existence of the periodical, since there were only twenty-eight subscribers. The periodical was distributed in twenty-two cities of the Peninsula besides La Havana, Mexico and Santa Cruz de Tenerife. It is obvious that there was a total lack of institutional support.

During the life of the periodical, six numbers, a total of eleven works, are published, nine of which are of Mathematics (starting from the third number it is only a newspaper of Mathematics) and two of Physics; six of these eleven works were written by the editor. From the works done by the editor, Sánchez Cerquero, we would like to mention the one entitled[3] "Interesting addition about the value of the semi circumference (radio = 1) up to 208 decimals"[4], where the author makes reference to an article of Rutherford in the *Philosophical Transactions* published in 1841, and to another of Schumacher that appeared in 1847 in the *Astronomische Nachrichten*. This reference is used to highlight the existence in Spain of centres where there were investigators with a good formation and mathematical information, and laudable international relationships.

en la

UNIVERSIDAD DE ZARAGOZA

TOMO II -- AÑO 1892

ZARAGOZA

Imprenta de C. ARINO, Coso, núm. 100, bajos

1892

This is the first Spanish periodical dedicated exclusively to Mathematics. It was published by García de Galdeano between 1891 and 1896 in its first period, and between 1899 and 1900 in a second stage; in this occasion it reappears with the idea of sensitizing public opinion and public powers in the face of the imminent educational reformations. This periodical had the five following sections: Articles and memoirs on mathematical topics (Doctrinal Section), Bibliographical Section, Articles on philosophy on mathematical topics, Historical topics and matters of varied information. In total, two series with seven volumes[5] were published.

"*The Mathematical Progress* was the first channel of accommodation of the mathematical Spanish community to the moulds of modern Mathematics in the international context, so much to internal and doctrinal aspects, for the work of conceptual diffusion that their pages show, like regarding the opening of relationship channels and internal and external

[3] In this work on the calculation of the π number with a total of 200 exact decimals, the author only corrects Rutherford's, but he insists in the uselessness of new works on this topic.

[4] Published in number 5 of the periodical. Pp. 143-146.

[5] For instance, the second volume corresponding to year 1892 consists of twelve numbers, with a total of 368 pages.

exchange between mathematical communities”[6].

El Progreso matemático

Año I. | Zaragoza 20 de Enero de 1891. | Núm. 1.º

Zoel García de Galdeano y Yanguas (1846-1924) was the creator, responsible founder, editor, collaborator and director of the periodical. He was one of the first Spanish mathematicians that participated assiduously, presenting communications and participating actively, in the International Congresses of Mathematicians. It is said that he was one of the first Spanish mathematicians in maintaining scientific correspondence[7] with other European mathematicians.

The *Archive of Pure and Applied Mathematics* of Valencia

This is the name of the second periodical published in Spain, dedicated to Physics-Mathematical Sciences, and the only one that is published in Valencia during the 19th century. Its founder was D. Luis Gonzaga Gascó y Albert (1846-1899). The publication of this periodical began in 1896 as a “monthly newspaper” published by Luis Gonzaga Gascó with the collaboration of Eduardo León, D. Mariano Belmás, and several Spanish and foreigners professors.[8]

In the first number of the periodical, their objectives were exposed, and they were: spreading the works of Valencia’s professors in particular and Spanish professors in general, establishing personal relationships with the mathematicians of the scientific international community, translating works published in foreign periodicals, and publishing scientific classical memoirs continuing the example of some scientific societies.

The periodical published a total of twenty numbers until the death of Gascó, who was the real heart and motor of the periodical, since in fact his personal effort made it possible that the periodical came out.

The Applicant of Toledo

Published by Ventura Reyes Prósper, at end of the 19th century in the city of Toledo. This periodical is mentioned by the Toledan professor Ricardo San Juan (1908-1969), professor of the Central University of Madrid, that had been student of Ventura Reyes Prósper in the Institute of Toledo; and however, so far it has not been physically found in any newspaper library.

Reyes Prósper is also well-known for being the first Spanish to publish in a foreign periodical of Mathematics of fame like *Mathematische Annales*, or in the Bulletin *of the Societé physico-mathematique de Kazán* (Russia), in the *Bulletin of the Société Géologique* of France, and in *The Educational Time of London*. Besides never abandoning his first discipline, the Natural Sciences, in Mathematics he devoted himself mainly to mathematical logic and to non-Euclidean geometries.

Quarterly Periodical of Mathematics of Saragossa

This periodical was published by professor D. José Ríus y Casas, in Saragossa. It had a relatively short life because it began in March of 1901 and ended in September of 1906. A total of twenty one numbers were made, which were distributed in five volumes plus one loose number. 72 articles and notes could be counted in total.

---

[6] Elena Ausejo, “Zoel García de Galdeano y Yanguas” in www.divulgamat.net. Section: History of Mathematics and Biographies of Spanish Mathematicians.

[7] He and his friend Ventura Reyes Prósper maintained scientific correspondence.

[8] It is according to their complete title. See page 163 of “Las Ciencias”, by Victor Navarro Brotons and Jesús Catalá Gorgues, in Peset Reig, Mariano (dir.), *Historia de la Universidad de Valencia*. Vol. III.

Professor Ríus attended the International Congress of Mathematics,held in Paris in 1900, together with García de Galdeano, and after his return, he began the publication of the periodical, as a continuation or substitution of the periodical *The Mathematical Progress* of Saragossa[9] that had just concluded its publication. In the first number of the publication, Professor Ríus y Casas exposed the reasons for the creation of this periodical, alluding to the completion of the publications of *The Mathematical Progress* of Saragossa and of the *Archive of Pure and Applied Mathematics* of Valencia, and to the need for this type of periodicals, that at that time did not exist in Spain and, however, were common in other countries.

The reason for the disappearance of the periodical was, as usual, the material impossibility of sustaining it by its editor, professor Ríus y Casas, although his international fame is demonstrated with the exchange that it maintained with 25 foreign periodicals.

Gazette of Elementary Mathematics – Gazette of Mathematics

It began its publication in Vitoria in 1903, by Angel Bozal y Obejero, who in the presentation of this new periodical alludes to the only existent periodical of Mathematics, *Quarterly Periodical of Mathematics*, directed by the intelligent and laborious professor D. José Ríus y Casas.

The first number of this new periodical, *Gazette of Elementary Mathematics*, sees the light in Vitoria in January 31st 1903; it seems to be the first mathematical periodical that is published in the Basque Country. In this first number a presentation is made indicating that the objective of the periodical will be writing about "all matter concerning Mathematics, exposed in an elementary way, without forgetting any of the multiple branches that form part of such universal science". In the number of December 1904, a change in the orientation of the publication is announced, suggested by a "considerable number of distinguishing becoming"; and after seeing the convenience, the director, "is delighted in announcing that, starting from the next number, the first that corresponds to year 1905, a suitable reformation will be introduced, suppressing for this purpose, in the title of the current periodical, the word "Elementary", with which it will remain reduced, gaining in generality, to *Gazette of Mathematics*, being understood that, in spite of this suppression, it will predominate in the bottom of their mathematical works, …., the genuinely elementary character. We will include, then, any article, note, problem, etc. of a little more superior character to the one used until now …"

In spite of its short life, thanks to the thousand eighty six pages published by several authors during the life of this periodical, some news about the Spanish scientists are known between the end of the 19th century and the beginning of the 20th, and they helped with their effort to the development of Mathematics in Spain, as well as to the interests of the mathematical community at that time.

---

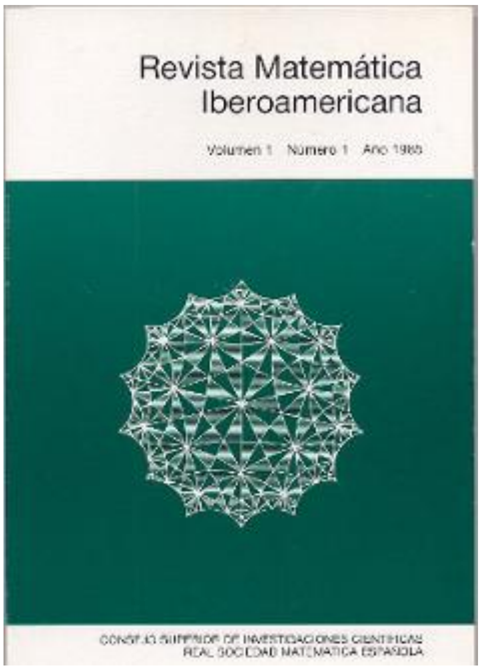
[9] In opinion of Javier Peralta in his book *La matemática española y la crisis de finales del siglo XIX*, see page 105, "The Mathematical Progress is without a doubt of more important that the Quarterly Periodical of Mathematics".

Journals of the SME

The Mathematical Spanish Society (SME) is finally created in 1911 with great hopes put on it, and a total of three hundred fifty nine partners, that in February of the following year have increased up to four hundred twenty three. It began to publish journals, starting from that same year, in May 1911, with a total of ten numbers in each academic course, organized in a volume. The title of the Journal, as displayed in its cover, is *Monthly Journal of Pure and Applied Mathematics, Historical and Pedagogic Questions*. The person responsible for the Journal is Julio Rey Pastor, who holds the position of Secretary of the SME.

The first volume of the Journal corresponds to the months from May 1911 to July 1912 (with the exception of the months of July, August and October 1911 and January and June 1912) and therefore it consists of ten numbers. The four following volumes go from October to July, like the academic cycle, although in some occasions two numbers come out together[10]. For the 1916-1917 course, that would correspond to the sixth volume, only one number in January 1917 and another in April of the same year are published. The reason for this interruption is the problems and discussions there have been on the Journal. When the Journal begins its fifth year of life, a publishing house appears[11] in which the structural problems of the Spanish Mathematics of that time are exposed to the readers.

In 1919, The Mathematical Spanish Society creates its second official journal, the *Hispano-American Mathematical Journal*, directed by Rey Pastor, which begins its activity with the publication of two volumes, opening the panorama to the twenty American nations that had been born to scientific life.



This Journal is still published, and it will change its name in 1985 to *Ibero-American Mathematical Journal*, which continues to be published at the present time, by the Department of Mathematics of the Autonomous University of Madrid, being from 2006 a scientific publication of the Society.

The *Mathematical Elementary Journal* was created by Julio Rey Pastor, like an organ of the student's mathematical circles between Madrid and Buenos Aires, in 1931. It was published under the auspices of the Spanish Mathematical Society

---

[10] For instance, were issued together: February and March 1914, June and July 1915, December 1915 and January 1916, and those of April and May 1916.

[11] *The Mathematical Spanish Society Periodical*, volume V, number 41(1915-1916), pages 1-10.

and the Argentinean Mathematical Society[12]. In 1932, José María Plans y Freyre in collaboration with José Barinaga Mata takes care of the composition of this *Mathematical Elementary Journal*. This Journal is born as the breakdown of the elementary part of the *Hispano-American Mathematical Journal*.

The *Mathematical Gazette* appeared in 1949 in replacement of the *Mathematical Elementary Journal*. The *Gazette* of the Royal Spanish Mathematical Society is the current expression organ of the Society. At present it exists a digital version in electronic form of the *Gazette*. It also exists, at present time, another periodical of the Society, entitled *Bulletin of the RSME*, is an electronic publication with weekly regular recurrence, where the last news on the activities of the Society and the mathematical community are included.

Journal of the Centre of Scientific Studies

In the Basque Country, the Republic started in 1931 and some intellectuals like Carlos Santamaría and José Oñate began the organization of what would be the origin of a Future university in this Spanish region that until this moment, for political reasons, had not been possible. So, with the idea of the creation of a future Faculty of Science, as a heart of this university, the Centre of Scientific Studies was created in San Sebastián on 28th May 1932 with the purpose of giving an incentive to the studies of pure and applied sciences as a help to industry and research.

The *Journal of Centre of Scientific Studies Section of Mathematics* is born in December 1932 with a format inspired in the French mathematical periodicals of that time and with a monthly character. There are published a total of 19 numbers in two-column pages, with a total of 188 pages until December 1934. The Director of the Journal is Carlos Santamaría. The Journal is distributed mainly for subscription in Spain and Latin America. There is a record of seven hundred subscribers with a total edition of one thousand copies. Its readers are mainly students that prepare their entrance at the Technical Schools and Secondary Education teachers.

The section of Physics of the *Journal of the Centre of Scientific Studies* was first published in March 1934, every month, until December of the same year. However, from January 1935, the two periodicals, section of Mathematics and section of Physics, were joined in a single publication. A total of thirteen numbers were made until March 1936.

Conclusions

The scientific Spanish periodicals of the end of the 19th century and the beginning of the 20th century have been appearing and disappearing due to various reasons. The most important mathematical periodicals of this period are shown in the following table.

The main inconveniences for the publication of scientific periodicals in the 19th century are economical difficulties. These reasons led to the disappearance of the majority of scientific periodicals, and in particular mathematical periodicals that were created in this 19th century and the first third of the 20th century.

[12] The Argentinean Mathematical Society is created under the impulse of Julio Rey Pastor in 1924, and it arrives to its term in 1927.

INVESTIGATING 19TH-CENTURY MATHEMATICAL JOURNALS: IMPORTANCE AND USE OF OTHER PERIODICALS IN *NOUVELLES ANNALES DE MATHÉMATIQUES* FROM 1842 TO 1870

Liliane ALFONSI

Université Paris Sud 11 – Orsay, FRANCE
liliane.alfonsi@u-psud.fr

Abstract

One way to investigate 19th-century mathematical journals is to see their importance and their use in other reviews. The purpose of my talk is to deal with this subject from an example, Nouvelles annales de mathématiques*, a French journal created by Orly Terquem in 1842, whose announced purpose was to prepare young men for the entrance examination of the Ecole Polytechnique. My study will cover the years 1842 to 1870, trying to answer the following questions:*
How many journals are there? Which journals are mentioned? On which occasions and on what themes? For what scientific, educational or political aims are they employed? Is there any evolution due to different editors, public expectation and political events?
In discussing those points I will focus my analysis, first, on a quantitative and qualitative study to measure the importance of the other periodicals on different subjects and at various times; and second, on a reflection upon the use of these journals in order to serve the editors' goals.

The topic of this communication is to investigate the importance and the use of others journals, by the different editors of *Nouvelles Annales*, from its creation in 1842 to 1870.

I wish to make it clear that what I mean by "other journals" is any regular scientific publication with mathematical articles, such as mathematical journals (*Crelle*, *Liouville*, etc..) but also academic publications (memoirs compilation or proceedings of an academy).

To understand the use of other journals in *Nouvelles Annales*, it is important to know that *Nouvelles Annales* is a journal for youngsters aiming at the Polytechnique and Normale schools.

This is the first page in 1842, which points out the complete title and aim of the journal as well as the editors':

NOUVELLES ANNALES
DE
MATHÉMATIQUES
JOURNAL DES CANDIDATS
AUX ÉCOLES POLYTECHNIQUE ET NORMALE
Rédigé par MM.
Terquem
Officier de l'Université, Docteur es sciences, Professeur aux Écoles Royales d'Artillerie
et
Gérono
Professeur de Mathématiques

It's not a journal for mathematical researchers, it's a journal for students and professors who are concerned by these schools and, more generally, for any people who have an interest for this level of mathematics.

Terquem and Gerono created it in 1842, but, as we see on the first page of the journal, Terquem seems to be the most important editor. *Nouvelles Annales* is his own journal and, as we will see, he uses it to serve his own goals and his own vision of what the teaching should be in high-level schools.

From 1842 to 1870, the editorial staffs were:

- 1842 creation, editors TERQUEM and Gérono

1862: the death of Terquem

- 1863: editors Gérono and Prouhet

1867: the death of Prouhet

- 1868: editors Gérono and Bourget

I would now like to explain what my method was.

At the beginning, I looked at the volumes from 1842 to 1870, page by page, noting all occurrences of other journals and trying to determine the most important years for my study.

After this first glance, it appeared to me that I had to focus on:

1842, 43, 44 because these are the first years of the journal.

1848 because it is the year of a revolution (against the king), which had an influence on École Polytechnique because École Polytechnique students were essentially republicans and because it was in that year, that studies became free at this school.

1850, 51, 52, 53, 54 because there was a very important program change in November 1850, and Terquem vigorously fought against this change, as we will see, using foreign journals until 1854.

1855 Terquem acknowledged himself beaten, and fought in another way.

1863, 64, 65, it is Prouhet's beginning as editor and a great change for *Nouvelles Annales* and the use of other journals.

1868, 69, 70, it is the same thing for Bourget.

For all of these years, I noted for all occurrences, the journal, the author, the subject and the nature of occurrence:

- either a full article of another journal
- or an extract or a revised version of the article
- or a *Nouvelles Annales* article based on another journal's article (contestation, prolongation…)

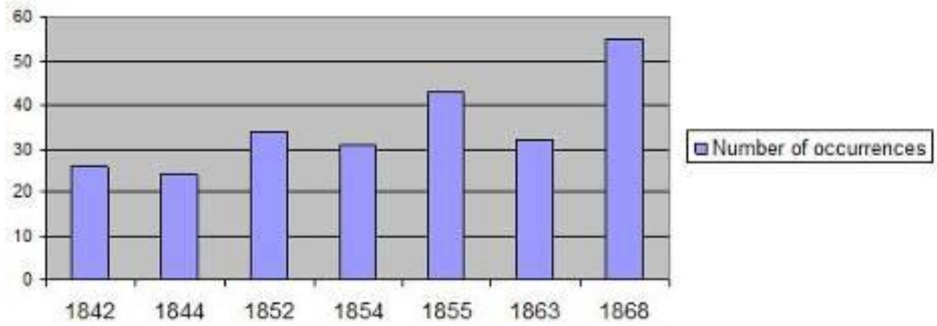
- or a summary
- or claims of priority order
- or questions asked / answers given
- or reference points cited and works used
- or miscellaneous.

After this work, what were the quantitative and qualitative results?

Quantitative results

The first quantitative results are the number of occurrences for every year pointed out.

Years	1842	1844	1852	1854	1855	1863	1868
Number of occurrences	26	24	34	31	43	32	55



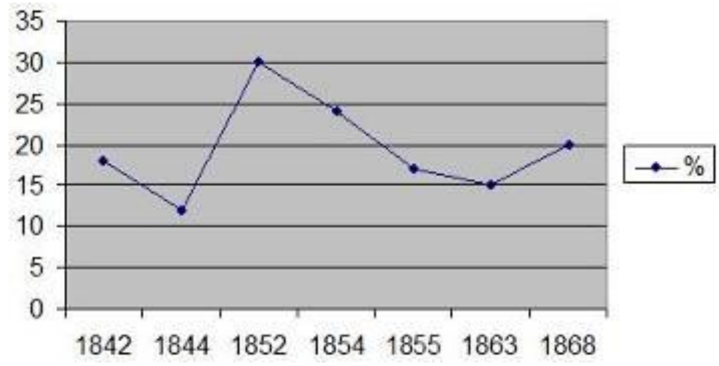
I only put on the graph significant years. We see that occurrences rise from 26 to 55 and that there is a regular progression with Terquem.

There is a peak in 1855 which has a lot of reasons; among these, the creation of a new part of *Nouvelles Annales*: The *Bulletin de Bibliographie, d'Histoire et de Biographie Mathématiques*.

Despite the peak in 1868 with Bourget's beginning as editor, it's not true that other journals had a more important role in *Nouvelles Annales*, in 1868 than in 1855. We see that point now with another graph, knowing that an article from another journal (***f another J***) is a *Nouvelles Annales* (***NA***) article made of

- either a full article
- or selected passages
- or summary
- or analysis
- or a reference to an article published in another journal or in academic publications.

years	1842	1844	1852	1854	1855	1863	1868
f another J	20	15	31	24	21	23	16
Total NA articles	113	129	103	150	121	149	79
%	18	12	30	24	17	15	20

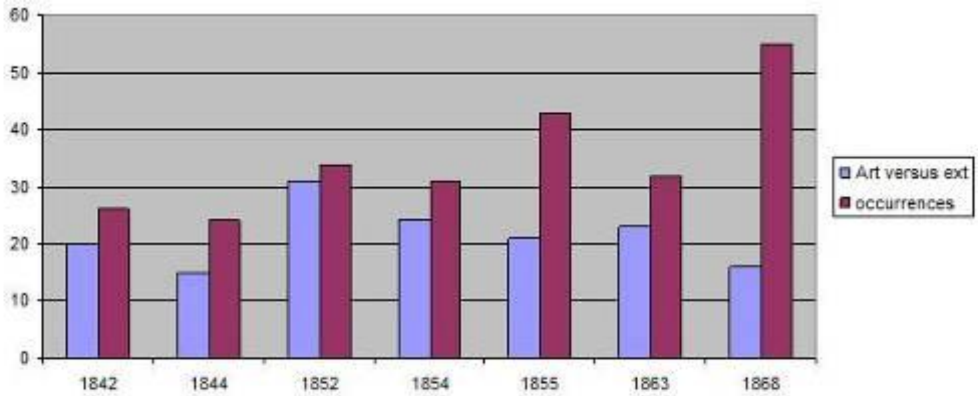


Here we have the curve of the percentage of foreign articles in the *Nouvelles Annales*. We can see that it is in 1852 with Terquem, that there are the most foreign articles in *Nouvelles Annales* whereas Bourget (1868) who had the most occurrences appearing, had far less foreign articles.

There is a trough in 1863 when Prouhet arrives and a peak in 1852 with Terquem's fight against the programs.

Another graph shows that with Terquem, occurrences are most of all, articles from other journals, except from 1855, because Terquem changes his mind and acknowledges himself beaten.

years	1842	1844	1852	1854	1855	1863	1868
f another J	20	15	31	24	21	23	16
occurrences	26	24	34	31	43	32	55



The most remarkable thing is the last diagram: With Bourget, in 1868, there is a peak of occurrences but a trough of articles from other journals because most of occurrences are footnotes reference points, questions, etc.

Qualitative results

For a qualitative study, I took, for every year, the five journals that have the greatest number of quotations.

With Terquem it's *Crelle Journal*, a German Journal very important for researchers that is number one. This is a proof of the use by Terquem of other journals in *Nouvelles Annales*: he tries, with researcher's journals, to raise the level of teaching mathematics in the higher French schools.

With Prouhet in 1863, Italian journals arrive first: the journal of Institute of Bologna and the *Annali delle scienze mathematiche*.

And with Bourget, in 1868, *Nouvelles Annales* sticks more closely to the Polytechnique and Normale schools' program and there are more old journals and French journals: the *Mémoires de l'Académie des sciences de Paris* and the *Annales de Gergonne*, a French journal which is over since 1854.

1842	***Acad Berlin***	***Acad Paris***	***Crelle***	***Gergonne***	***Journal X***
number	**4**	3	3	**7**	**4**

1854	***Arch Math Grunert***	***Camb& Dublin***	***Crelle***	***Gergonne***	***Liouville***
number	**4**	3	**7**	2	**4**

1855	***Acad Paris***	***Ann sc math***	***Astro nachrich***	***Crelle***	***Liouville***
number	**9**	2	2	**10**	4

1863	***Acad Paris***	***Ann sc math***	***Crelle***	***Instit Bologne***	***Liouville***
number	2	**4**	2	**5**	2

1868	***Acad Berlin***	***Acad Paris***	***Bull stor M&P***	***Gergonne***	***Liouville***
number	4	**8**	4	**6**	5

The use of other journals by the different editors of *Nouvelles Annales*

Now I will try to show the use of other journals by the different editors and I begin with Terquem.

1. Terquem (1842-1862)

As we can see in the first example below, articles are clearly noted as being from another journal (here *Crelle's journal*, 1835), in the beginning of the text, the author (here Jacobi) is named at the same time.

DE L'ELIMINATION DE LA VARIABLE

entre deux équations algébriques.

Par C. G. J. JACOBI, professeur à Kœnigsberg. (Crelle, XV, 101, 1835, latin.)

—

1.

Entre les diverses méthodes d'élimination qui ont été proposées, il en est une que je me rappelle avoir lue jadis dans les ouvrages élémentaires composés par le célèbre Bezout, et qui se distingue avantageusement des autres à divers titres. Mon but est d'exposer brièvement cette méthode et d'y ajouter diverses observations (*).

Nous pouvons supposer que les deux équations sont de même ordre; car si l'une des équations est d'un ordre inférieur à l'autre, il suffira d'égaler à 0 les coefficients des puissances manquantes. Soient donc ces équations :

$$f(x)=a_nx^n+a_{n-1}x^{n-1}+a_{n-2}x^{n-2}\ldots+a_0=0,$$
$$\varphi(x)=b_nx^n+b_{n-1}x^{n-1}+b_{n-2}x^{n-2}\ldots+b_0=0.$$

(*) Les auteurs du programme d'admission à l'École polytechnique n'ont pas eu la main heureuse en choisissant parmi les méthodes d'élimination celle du p. g. c. d ; la plus mauvaise, et tellement longue, qu'on a été obligé de *proscrire* la partie essentielle, la discussion des facteurs étrangers. Ce programme aurait besoin d'être totalement remanié, car il domine et entrave l'enseignement.

It's an opportunity for Terquem to give his advice on Polytechnique program and to criticize it in a footnote.

Often Terquem also gives his advice in long commentaries after an article, as we can see in this second example. After a Salmon's article in the *Cambridge & Dublin Mathematical Journal* (1848), in which Salmon says that English students learn cono-spheric curves, Terquem hardly criticizes the higher schools' programs in France:

> «Teaching in France, has been made throughout the year on the basis of conics which nevertheless remain cono-spheric cases, because the plane constitutes a particular case of a sphere. The fact that these curves are not mentioned in colleges is a pity; ***but that they are not even mentioned in the higher schools such as the École Normale and the École Polytechnique, is totally unacceptable.***
> ***To the credit of German and English universities, these curves are commonly taught which is perfectly right***.»

His criticism on the Polytechnique program, about conics, is very strong and he doesn't mince his words.

Terquem uses also articles of foreign journals as an educative tribune and to criticize French teaching.

Giving a summary of the Dublin calendar for 1850, he writes:

> «I read with great interest a report on Oxford University […] It finished with remarkable conclusions that would be of a great interest in France, when the French government will be able to do other things than an arms' factory, sometimes in favour of, sometimes against University and when the principal goal will be education and not hierarchical trivial rewards. ***These questions show what is the state of teaching and enable us to make comparisons that, for mathematics, as I can see, aren't to our advantage. Overseas, there is a spirit of progress: teaching follows science. In France, there is a stationary spirit, often, retrograde spirit***.»

He uses caustic humour to criticize teaching choices for the Polytechnique program, always starting from other journals:

In 1850,

> «In *M. Crelle's Journal* (t. XL, 2) there are three articles on number theory, by M. E.-E. Kummer, a famous professor at Breslau University. M. Crelle has acquired eternal rights to the mathematicians' gratefulness for having published tremendous works on this most noble, generous and sublime part of mathematical science. (<u>See the note at the end</u>)
>
> ***<u>Note</u>. The number theory is very little known and even disdained in France and for good reasons. This theory doesn't make wheels turn round, water gates open, gas condense and, worse than all that, isn't used in examinations; because of these reasons, calculating persons, in a majority position, ask why there is any need to study a theory which doesn't bring anything. My stubborn intelligence doesn't give me any answers to such questions. Rumour has it, by the same calculating mind that the next program for the École Polytechnique will throw away rational mechanics by Lagrange, Laplace, Poisson, and will put in place industrial mechanics***. As I believe in decency, I don't believe in this news: there is some misunderstanding.»

And in 1851, concerning Hess's article in Crelle's Journal:

> «Determinants (Cramerian functions) today rule over all mathematics. So, I suppose, it's a right thing that they have been taken away from the new program. They have been replaced by the auxiliary plane, logarithm, elementary work which have taken fruitfully their place; lovely triad, without forgetting Saint Gunther's ruler that every mathematician needs to have all the time in his pocket or in his hands.»

With the same humour, he also strongly criticizes Le Verrier, the most important responsible of the Polytechnique program, for his choices, in contradiction with his own work, starting from the *Connaissance des temps*, which is a publication of French Institute:

> «In the Connaissance des Temps for 1849, there is, in a Le Verrier's report on Uranus planet, lots of linear equation systems with four unknowns; exercises of the day, taken from good authority. ***At page 169, he uses determinants. That's what we shouldn't copy. Because we have removed these formulae from the Education program; but how would this illustrious mathematician have used them if they hadn't been taught to him?***
>
> (*) The famous mathematician astronomer used the Sturm theorem judiciously; An academician of the same name has taken away from the education program this theorem as belonging to high-level theory, useless thing; A representative of the same name has declared a high theory to be an indispensable thing. Do these three names designate the same person? O. TERQUEM.»

After an article from M. Jacobi, (*Crelle's Journal*, t. XXX, p. 51-94; 1846) concerning a particular system of first degree equations Terquem wrote (1851):

> «Astronomic application: The aim of the present report is not purely analytical. The illustrious author offered to put forward a simple process to solve numerically the equations present in the theory of the secular perturbations of the planets. ***The numeric data are taken from the remarkable work of Le Verrier on the same subject. The compared results show that the Jacobi process is far more exact than the one Le Verrier used***. ***Due to the dire lack of a journal of Astronomy, M. Liouville would fill the gap, as far as he could, to such a shameful lack for the country by inserting in extenso the report of the illustrious Prussian*** and other analogous works in his precious journal also destined to applied mathematics.»

After this vigorous fight, Terquem in 1855 acknowledges himself beaten. He doesn't think that the *Nouvelles Annales* hadn't followed sufficiently the Polytechnique program, but that it was the official program, which hadn't given sufficient attention to the *Nouvelles Annales* and their ideas. That's what he writes in the editorial of 1855:

> «The *Nouvelles Annales de Mathématiques* are entering their fourteenth year and despite the sacrifices we have often imposed ourselves, ***they haven't yet, we have to admit, been able to give us a just remuneration***. Would they have missed the goal pursued, to offer youngsters aiming to the Ecoles Polytechnique and Normale the solutions to problems that can interest them most? We think not. In fact, the *Annales* have dealt with the beautiful and difficult questions of passed exams, and also ***the questions of the new exams, when they presented some interest***. There was given numerical calculus exercises, logarithms with a scope that are to be found nowhere else. ***Despite the narrow position given to the Nouvelles Annales by the official programs,*** we shall as from January 1855 make new efforts in the interest of science.»

And he announces the creation of the *Bulletin de Bibliographie, d'Histoire et de Biographie mathématiques*, where he will put from now on, the most parts of articles of others journals:

> «***Each month there will include an added brochure with at least a pagination of its own under the title: Bulletin de Bibliographie, d'Histoire et de Biographie mathématiques, par M. O. Terquem***. The title of the brochure makes the object clear. The history of Science is that of the human mind […] All the dignity of Man is in the thought process. Mathematics are a perpetual thought process. May we be worthy of our new mission!»

2. Prouhet (1863-1867)

It is Prouhet's arrival, which gives a greater respect of programs.

He decides the end of the *Bulletin*, initiated by Terquem as we have seen before, and gives fewer articles of other journals but more quick summaries in biographical articles.

In fact, the *Nouvelles Annales* loose their great originality, due to Terquem, to become only a way to prepare Polytechnique and Normale examinations seriously.

The part "questions asked / answers given" takes more and more place in the journal, and when articles are chosen, they are articles the subject of which is part of the program examination.

For the articles of other journals, he takes only fragments and he rewrites them. He only puts as a footnote the sources of the articles, such as the author and the name of the journal, whereas Terquem is more explicit on his sources and makes it perfectly clear where his articles are taken from.

We can see the difference between the two editors, looking at the first example of Terquem (article by Jacobi taken from the *Crelle's journal*) and at the example of Prouhet below:

It is only in a footnote that we learn in which journal and from what author Prouhet took the article.

Prouhet definitively stops using other journals with the aim of giving advice and criticism on the programs.

SUR LE NOMBRE DES DIAGONALES D'UN POLYÈDRE (*).

Je désignerai par f le nombre des faces, par s le nombre des sommets et par a le nombre des arêtes du polyèdre. On sait qu'il existe entre ces trois quantités la relation

$$f + s = a + 2 \tag{1}$$

découverte par Euler.

(*) Ce problème a été traité par M. Henri Binder dans les *Archives* de Grunert, t. VIII, p. 221.

3. Bourget (1868-1870 –the end of our study)

This trend increases with Bourget as editor. He chooses to put in the *Nouvelles Annales* still fewer articles from other journals and more historical articles than mathematical articles. The fact that an article is taken from another journal is much worse indicated as it was by Prouhet.

As an example which we can see below, we will know that «Etude sur des surfaces algébriques», is taken from the *Journal des savants*, and its author only at the end of the article, and written in very small letters:

c'est-à-dire que par chaque point du plan il passe deux ovales se coupant à angle droit, dont l'étude a conduit récemment M. Darboux à une démonstration nouvelle et fort élégante du célèbre théorème d'Euler, sur l'addition des fonctions elliptiques. J. Bertrand.

(Extrait du *Journal des Savants*.)

Bourget uses of other journals most of all in footnotes and used as reference points. He respects official programs and so the articles of *Nouvelles Annales* are, for the most, of the Polytechnique and Normale schools' level and made especially by authors who write for the journal. *Nouvelles Annales* becomes a journal which lives essentially in autarky.

Conclusion of this study from 1842 to 1870

For these years, the most important editor was Terquem, who founded *Nouvelles Annales* in 1842. He wanted to use the journal for the aim of influencing on the program examination of Polytechnique and Normale schools and, more generally, French teaching, in the sense of higher level.

He took articles in researchers journals (*Crelle*, *Liouville*, etc.) that he put in *Nouvelles Annales* as full articles or long selected passages, by one hand to improve the level of students and teachers who bought his journal, and by another hand to write what the government and the men responsible for mathematical French teaching had to do.

He also took articles on the history of mathematics to give examples to follow and a more general mathematic culture to youngsters.

For all articles, the author and the original journal are mentioned at the beginning and very clearly, and Terquem used of their authority to serve his purpose and to give lessons to the ministry of French education and his staff.

It is only in 1855 that he changed his mind, seeing that his journal was not very much bought, because of the non-respect for the real program examination. So he took minus mathematical articles from researcher journals and more from books or revues of mathematical history, creating the *Bulletin de Bibliographie, d'Histoire et de Biographie mathématiques* in an appendix of *Nouvelles Annales*.

His successors, Prouhet and Bourget, were more classical. They did not use many articles from researcher's journals, and the few they used were in footnotes or in cited referenced points. Criticism of French teaching and of program examination, which was the principal aim of articles of other journals with Terquem, disappeared completely. And if the *Nouvelles Annales* was more sold, it lost (from 1863 to 1870) his high mathematical and culture level, his function of mathematics teaching consciousness and, as Terquem said, its mission: «All the dignity of Man is in the thought process. Mathematics are a perpetual thought process. May we be worthy of our new mission!»

Abstract

This presentation examines the emergence of the Journals of Mathematics in the 19th century and their role in the diffusion and the progress of this science as practiced in 19th century Italy by Giusto Bellavitis (1803-1880) in the several issues of his Rivista di Giornali*, published from 1859 to 1879.*

The present report stays within the field of the researches concerning the PRIN project on "The birth of the Italian School of Mathematics: Publications of Electronic Archives and Correspondences" coordinated by Prof. Aldo Brigaglia from Palermo University. In the project, for what Giusto Bellavitis is concerned, his correspondence with Placido Tardy, an Italian mathematician and also Rector of Genoa University, has been recently studied. In his letters Bellavitis announced the start of the publication of his *Rivista di Giornali* in 1859, in the *Atti dell'Imperial Regio Istituto Veneto di Scienze Lettere ed Arti* in Venice, and he informed about the following issues up to 1879. Our aim is to consider the topics the *Rivista di Giornali* deals with and its circulation in the main universities and research centers. In particular our interest is focused on reviews related to the articles published in the *Comptes Rendu*, in the *Nouvelles Annales de Mathématiques, in the Journal de Crelle, and in the Annali di Matematica pura e applicata*.

As for Giusto Bellavitis's biography we can give a brief outline.

He was born in Bassano del Grappa (Vicenza) on the 22nd November 1803 and he died in Tezze (Vicenza) on the 6th November 1880. He began his studies under the guidance of his father Ernesto, but he was essentially a self-taught person and this experience made him especially sensitive to teaching.

After some time spent as a municipal employee in 1843 he was appointed Mathematics teacher at the Liceo of Vicenza.

In 1845 he was awarded an honorary degree in Philosophy and Mathematics (*Laurea honoris causa*) at Padua University where he taught descriptive geometry, then advanced geometry, theory of probability, physics, complementary algebra and finally co-ordinate geometry. In 1840 he became a member of the Istituto Veneto. Elected member of the Society of XL in 1850, in 1855-57 served as Inspector of Scuola Reale Superiore di Venezia, then in 1866 he became Senator of the Regno d'Italia, and in 1866-67 Rector of Padua University.

In 1880 he died accidentally tumbling down the stairs at home.

He published 223 works and the *Rivista di Giornali*, and he gave relevant contributions to analysis, resolution of equations, curves classification, complex numbers algebra; he also developed some studies in physics, in particular optics and electrophysics and in chemistry.

He studied algebra of imaginary numbers on geometric base and he achieved his first work on *equipollenze* in 1832. In 1835 [1] he published a fundamental paper on this topic influenced by some articles and books by Buée [5], Poncelet [16] and Steiner [17].

Previous works on the same topics, but unknown to Bellavitis in 1832, were developed by Carnot [8] and Möbius [15]. Similar methods were later developed by Grassman [12] and Hamilton [13][1].

The scientific work of Bellavitis has been extensively analyzed in recent publications [4], [6], [7], [9], [10], [11].

Bellavitis together with Genocchi, Tardy and Chelini belongs to a generation which played a relevant intermediary role between the group of the old masters in the pre-unitarian Italy (Bordoni, Piola, Chiò, Mossotti) and the generation of young mathematicians (Beltrami, Betti, Brioschi, Casorati, Cremona) who developed their research after the Italian unification. Bellavitis and his colleagues gave relevant contributions to the birth of the Italian school of Mathematics thanks to their international relationships[2] and in particular Bellavitis can be considered not only one of the vector calculus founders, thanks to his method of *equipollenze*, but also the main introducer in Italy of the new European developments in this field.

The *Rivista di Giornali* was published from 1859 to 1879 in *Atti dell'Imperial Regio Istituto Veneto di Scienze Lettere ed Arti* in Venice.

It is worth noticing that Bellavitis started publishing his *Rivista* in the year following Betti's, Brioschi's and Casorati's European journey in September 1858 as if he wanted to open Italy to wide perspectives or to strengthen the attempt to "make Italy worldly".

The First Issue of the Rivista was published on the 22nd August 1859, with the title:

"Rivista di alcuni articoli dei Comptes Rendu dell'Accademia delle Scienze di Francia del prof. Giusto Bellavitis, Membro effettivo dell' I.R. Istituto Veneto di Scienze, Lettere ed Arti".

From Comptes Rendu we give a list of the arguments considered by Bellavitis (on the left of the following table) and the authors of the articles on these arguments (on the right of the table):

Interpolazione approssimata	Hermite[3]
Generazione spontanea	Quatrefages
Corpi semplici	Dumas and Despretz
Spiriti picchiatori	(Conversazione)

[1] In a previous session of this Conference a very interesting lecture on these authors has been delivered by Josep Manel Parra Serra (Barcelona University) "Geometric Algebra versus Vector Algebra as Physical Mathematics: Bridging Past and Future".

[2] The journey made in 1858 by Betti, Brioschi and Casorati in the most relevant European centers of research –organized by Genocchi and Tardy– has played a central role in the innovation of Italian mathematical research and has been extensively quoted by Volterra at the International Congress held in Paris in 1900 [18].

[3] The authors and the journals are quoted from the original issues of the *Rivista* frequently without the initials of the first name and according to the abbreviations used by Bellavitis.

The Second Issue was published, with the same title of the First, on the 18th June 1860. In the following table the subjects treated and the corresponding authors are listed.

Risoluzione delle equazioni e decomposizione delle frazioni	Valz, Ferola, Montucchi, Vieille
Ricerche sui numeri primi	Polignac
Formule per le congruenze	Sylvester
Condizione di decomposizione delle cubiche	Painvin
Cangiamento di variabile indipendente	Spitzer
Calcolo delle variazioni	Lindeloff
Porismi di Euclid	Chasles
Proprietà generali dei poliedri	Prouhet, Bertrand
Proprietà dell'ellisse	Lino de Pombo
Curve e superficie derivate	W.Roberts
Coni omofocali	Chasles
Generazione delle curve gobbe	Jonquieres
Carte geografiche	Tissot
Linee di curvatura	Aoust
Coordinate curvilinee	Lamé and Valson
Curvatura delle superficie	Babinet
Equivalenza delle copie	Tessan
Urto dei corpi	Poisot
Moto della terra	Perrot
Macchina pneumatica	Gairaud
Alimentatore delle caldaie a vapore	Gairaud
Ascensione capillare	Jamin
Cangiamento di volumi di alcuni sali	Tissier
Calore sviluppato nelle combinazioni chimiche	H. Sainte-Claire Deville
Ombre colorate	Babinet and Fournel
Striscie oscure negli spettri colorati	Robiquet
Aberrazione della luce	Fizeau, Faye and Tessan
Comete	Faye
Calcoli Astronomici	Puiseux
Fulmini Globulari	Tessan
Nuove pile voltiane	Davy
Produzione dell'ozono	Le Roux
Equivalenti chimici	Baudrimont
Agricoltura	S. Cloez and E. Dufour
Ipnotismo	Tigr

As we can see, Bellavitis's interest as a reviser is mostly oriented to the French culture and research and to one of its most important journal: *Comptes Rendu*.

Being particularly sensitive to French culture in the title of the Third Issue Bellavitis referred to another prestigious journal: the *Nouvelles Annales de Mathématiques*. In fact in March 1861 the title of the *Rivista* changed and became "*Rivista di alcuni articoli dei Comptes Rendu dell'Accademia delle Scienze di Francia e di alcune questioni des Nouvelles Annales de Mathématiques del prof. Giusto Bellavitis, Membro effettivo dell' I.R. Istituto Veneto di Scienze, Lettere ed Arti*".

The arguments treated and the corresponding authors from the Comptes Rendu are the following:

Macchina da calcolare	Dubois
Criterio per la separazione delle radici	Turquan
Numeri bernoulliani	Thoman
Somma di degli angoli di un poliedro anche stellato	Valat
Classificazione dei poliedri	Bretond
Cellette degli alveari	Villich
Relazioni di posizione tra due figure uguali	Chasles
Linee di curvatura dei ditomoidi	Aoust
Carte geografiche	Tissot
Ombra dell'elica	Dunesme
Pendolo di Foucault	Dehaut and Laroque
Derivazione in Meccanica applicata alla doppia rifrazione	D'Estocquois
Stato globulare dell'acqua	De Luca and Sudre
Freddo artificiale	Carre
Pluvioscopio	Herne and Mancon
Influenze della luna	Faye
Tuono musicale	Govi
Della visione	Giraud and Teulon
Generazione spontanea	Pouchet, Pasteur and Mantegazza
Concepimento	Demaux
Antidoto per l'eterizzazione	Ozanam and Zinno
Agricoltura	Guerin- Meneville and Paravet

The following "Quéstions", taken from the *Nouvelles Annales de Mathématiques*, are dealt with and Bellavitis gives his own solutions:

Teorema del Côtes
Sul perimetro dell'ellisse
Classificazione di una tritoma
Generazione di una triattomena
Tetraedro dato dalle posizioni di tre altezze
Problema di situazione
Disposizione sullo scacchiere di otto regine

Therefore the first three years of the *Rivista* were meant to introduce in Italy ideas and results from the European scientific culture, the French one above all.

From the Fourth Issue on, dated 1862, the title simply became: *Rivista di Giornali*, still published in Venice at "Istituto Veneto". Here Bellavitis greatly changed the organization of his critical revisions.

Author's specifications about his aim are very relevant:

> *"The increasing number of valuable mathematical works published in Europe and America […requires] a well structured collection of all the wide doctrine […] and longs for a repertoire of everything that is going to be published in mathematical science […]. It takes a long time to understand the meaning of denominations and operational symbols, and to get a right idea of the aim and the main results […]. Furthermore it is difficult to collect all the reviews that are periodically published and to understand the different languages they are written in. […]. Now, the mathematicians would avoid this reciprocal waste of time by publishing the articles of a Repertoire; and everyone could study the article he liked most […].*
> *Allow me to outline the arrangement of a repertoire suitable for my own use. In one book only, the different categories of human knowledge are included in separate pages; for each category I write down all the articles and abstracts following a progressive number, by registering the author's name and the title of the review or the work in general, and the quotations of the previous or following articles, related to it in proper columns […]"*

We can notice that Bellavitis refers to the style of his "Otto Repertori", a fundamental subject in his personal studying method and scientific data collection. In a "Repertorio" he registered theorems, problems, theories, debates, proposed or solved by the most important mathematicians of the time, following a chronological and thematic order, containing precise information about the author, the article and the journal. That thanks to the "Repertori" it is evident one could verify immediately if a given subject was been discussed, by whom, in what period and in what issues. Bellavitis also points out some subjects he deals with in the "Repertori":

> *"aritmetica, algebra, geometria (elementare, descrittiva, piana, sferica, etc.), geodesia, analisi della probabilità, meccanica, idraulica, meccanica dell'universo, merilogia ossia scienza delle azioni molecolari e dei relativi fenomeni, teoria delle vibrazioni ed acustica, aerologia, scienza del calorico, ottica, azioni chimiche della luce, magnetismo, elettricismo, chimica, meteorologia, astronomia, mineralogia, fitologia, zoologia, microbiologia, geografia fisica e geologia, arte dell'ingegnere, agricoltura ed economia domestica, medicina, arti, belle arti ed estetica, letteratura, geografia e statistica, storia civile, storia letteraria, filosofia, scienze sociali, scienze naturali, biografie, miscellanea."*[4]

In the following list we give the arguments and the authors of the articles from the Comptes Rendu analized in the Fourth Issue of the *Rivista* (1862):

Algebra	Heegmann; Sylvester
Aritmetica	C. Polignac
Calcolo sublime	Rouché
Geometria dello Spazio	C. Polignac; Chasles; Transon, Chasles and Bonnet; Bour and Codazzi; Sylvester and Chasles; Sylvester; Cremona
Geodesia	Faye
Meccanica dell'Universo	Abbadie
Scienza del Calorico	Carvallo, Clausius; A.Loir and Ch. Drion; L.Dufour
Ottica	Giraud-Teulon; Faye; Briot
Elettricismo	Marié and Davy; Moncel
Chimica	Fremy

[4] A first analysis can be found in N. Legnazzi [14] pp. 25-27 and footnotes from 24 to 29 (pp. 88-105).

Metereologia	Renou; Houzeau
Astronomia	Faye
Zoologia	Em. Rousseau
Microbiologia	Pouchet; Pasteur; A. Terreil
Geografia fisica	Griniaud de Caux
Agricolt.e Ec. Dom.	G.Saint-Hilaire; Guerin-Meneville

Here the data from *Nouvelles Annales de Mathématiques*:

Algebra	Painvin
Geometria piana	Paul Serret; Mannheim; Jonquières
Geometria dello spazio	Faure

In his introduction of Fifth Issue of the *Rivista* (1862) Bellavitis explains:

> *"Although what I define as a review has the structure of a Repertoire, it is evident that more often it is only the expression of my personal point of view; and whoever wants to get the right idea of the whole articles will have to read them in the original form, for I wish I could be an inciter. Even the quotations I made are not meant to introduce the history of every single subjects, I won't do anything but giving the example of what could be useful to let the young scholar be guided in the right way to get the knowledge of the wide field every mathematical question is a part of."*

and in the third part of the same issue he specifies:

> "I wish these debates could entreat the young people living in our provinces to study the fruitful geometrical theories, and for their benefit I add the missing quotations, as far as I know […]
> [...] It seems regrettable to me that in some articles even one only word, whose meaning is not generally adopted ,is used without being explained, as feeling like the author disdains from reading his work all those who do not consider foreign works, where that word was used, in their thinking."

In the fourth part of the Fifth Issue Bellavitis pays great attention to some articles by the Italian mathematicians. In the following we give the lists of the periodicals examined and the topics considered:

> Topics:
> *Arti scientifiche, Algebra, Calcolo sublime, Geometria piana, Geometria elementare, Geometria dello spazio, Ottica , Meccanica, Meteorologia, Mineralogia*
>
> Periodicals:
> *Annali di Tortolini, Memorie Istituto di Bologna, Nouv. Ann. Math., Comptes Rendu, The Quart. J. of Math., Rend. e Mem. Accad. Napoli*

It is interesting to analyze the aims of the reviewer. The first three issues deal with French and German periodicals in order to spread into the Italian community new ideas and recent results of the European research centres, while in the following issues Bellavitis' aim consists in involving new generations into new research subjects and into close confrontation with European scientists.

Also the Sixth Issue of *Rivista di Giornali* (1863) contains very useful observations to understand Bellavitis's thought:

> "The topics dealt with by most journals stimulates experimentation and confront between the different methods followed by modern science: among the problems raised in the *Nouvelles Annales par Terquem et Gérono* I solved some of them, the ones under the numbers [...]"
> "I do not think useless a new publication of the questions posed and not yet solved in order to stimulate Italian Geometers [...]
> In the *Giornale di Napoli*, which tries to follow the example of Terquem, some interesting questions are posed [...] The new *Giornale di Napoli*, interested in the diffusion of the mathematical knowledge and in stimulation of young minds, accepts the articles by these young researchers, who in the future will join the crown of mathematicians with which the city shines"

The following lists indicate topics and periodicals considered from the Sixth Issue to the Fifteenth one.

Sixth Issue *Rivista di Giornali* – 1863

Topics:
Algebra, Geometria piana, Geometria dello spazio, Idraulica, Calcolo sublime, Geometria elementare e descrittiva, Meccanica

Periodicals:
Atti Istituto Lombardo, Annali del Tortolini, Rendiconti e Memorie Accademia Napoli, Journal Crelle, Arch. Von Grunert, Memorie Istituto di Bologna, Memorie Accademia di Torino, Giornale Matematico di Napoli, Annali delle Università Toscane

Seventh Issue *Rivista di Giornali* – 1864 and 1865

Topics:
Arti Scientifiche, Scienze sociali, Algebra, Fitologia, Geometria piana, Geometria dello spazio, Geometria sferica, Calcolo sublime, Geometria elementare e descrittiva, Meccanica

Periodicals:
Atti Istit. Lomb., Rend. e Mem. Accad. Napoli, Journal Crelle, Mem. Istit. Bologna, Mem. Accad. Bologna, Giorn. Mat. di Napoli, Nouv. Ann. Math. par Terquem et Gérono, Comptes Rendu, The Quart. J. of Math., Memor. Soc. Ital, Proceeding of the R. Society, The Educat. Times

Eighth Issue *Rivista di Giornali* – 1866 and 1867

Topics:
Algebra, Elettricismo, Geografia, Geometria piana, Geometria dello spazio, Letteratura, Calcolo sublime, Geometria elementare e descrittiva, Meccanica

Periodicals:
Atti e Rend. Istit. Lomb., Bull. Acad. Pétersburg, Rend. e Mem. Accad. Napoli, Journal Crelle, Mem. Istit. Bologna, Ann. del Tortolini, Giorn. Mat. di Napoli, Nouv. Ann. Math. par Terquem et Gérono, Memor. Soc. Ital., Philos. Magazine, Proceeding of the R. Society, Messeng. of Math., Ann. Der Phys

Ninth Issue *Rivista di Giornali* – 1868 and 1869

Topics:
Algebra, Geometria piana, Geometria dello spazio, Calcolo sublime, Geometria elementare e descrittiva

Periodicals:
Atti Lincei, Atti dell'Ist.d'Incor. in Napoli, Comptes Rendu, Journal Crelle, The Quart. J. of Math., Ann. Del Tortolini, Giorn. Mat. di Napoli, Nouv. Ann. Math. par Terquem et Gérono, Journal Liouville

Tenth Issue *Rivista di Giornali* – 1870 and 1871

Topics:
Algebra, Analisi delle probabilità, Fisica, Geometria piana, Geometria dello spazio, Geometria sferica, Geometria elementare e descrittiva, Meccanica, Meteorologia

Periodicals:
Annali di matem. di Milano, Ann. del R. Museo industriale italiano di Torino, Ann. R. Ist. Tecnico Udine, Atti Accad. Gioenia, Atti Istit. Veneto, Comptes Rendu, Giornale dell'Ital. Letter., Journal Crelle, The Quart. J. of Math. London, Mem. Istit. Bologna, Giorn. Mat. di Napoli, Nouv. Ann. Math. par Terquem et Gérono, Memor. Soc. Ital, Journal Liouville

Eleventh Issue *Rivista di Giornali* – 1871, 1872 and 1873

Topics:
Algebra, Geometria piana, Geometria dello spazio, Geometria elementare e descrittiva, Calcolo sublime, Idraulica, Meccanica

Periodicals:
Annali di matem. di Milano, Bullet. Sc. Math. Paris, Comptes Rendu, The Quart. J. of Math. London, Giorn. Mat. di Napoli, Nouv. Ann. Math. par Terquem et Gérono, Il Filocritico, Annali Sc. Norm. di Pisa, Trans. Cambr. Phil. Soc., Archiv der Math.Von Grunert, Politecnico di Milano

Twelfth Issue *Rivista di Giornali* – 1873 and 1874

Topics:
Arti Scientifiche, Aritmetica, Algebra, Analisi delle probabilità, Astronomia, Calorico, Chimica, Elettricismo, Filosofia, Fisica, Fitologia, Geometria piana, Geometria dello spazio, Geometria sferica Geometria elementare e descrittiva, Calcolo sublime, Geodesia, Meccanica, Meteorologia, Microbiologia, Mineralogia, Ottica, Scienze sociali, Zoologia

Periodicals:
Abhandl. Böhm. Gesellsch., Analectes. Athènes , Atti Lincei, Atti Accad. Torino , The Quart. J. of Math. London, J. École Polytéchnique , Giorn. Mat. di Napoli, Nouv. Ann. Math. par Terquem et Gérono, Archiv der Math.Von Grunert

Thirteenth Issue *Rivista di Giornali* – 1876 and 1877

Topics:
Acustica, Arti Scientifiche, Algebra, Analisi delle probabilità, Calorico, Geometria piana, Geometria dello spazio, Calcolo sublime, Geometria elementare e descrittiva

Periodicals:
Assoc. Franç. Pour l'avancement. des sciences, Atti R. Accad. Torino, Atti Istit. Veneto, Atti e Rend. Istit. Lomb, Rendic. e Mem. Accad. Napoli, Nouvelles Annales Mathématiques par Terquem e Gérono

Fourteenth Issue *Rivista di Giornali* – 1877

Topics:
Algebra, Chimica, Geometria piana, Geometria dello spazio, Calcolo sublime, Geometria elementare e descrittiva, Meccanica,

Periodicals:
Archives Néerlandaises, Atti R. Accad. Torino, Comptes Rendu, Rendic. e Mem. Accad. Napoli, Giorn. Matem. Di Napoli, Nouvelles Annales Mathématiques, par Terquem e Gérono, Mem. Spettroscopisti Italiani, Mém. Soc. de Bordeaux, Mem. Accad. di Bologna, Monthly Notice of the R. Astron. Soc.

Fifteenth Issue *Rivista di Giornali* – 1879

Topics:
Algebra, Geometria piana, Geometria dello spazio, Geometria sferica

Periodicals:
Atti Istit. Veneto, Nouvelles Annales Mathématiques par Terquem e Gérono

An article published in 1869 by M.J.Houel on the *Nouvelles Annales de Mathématiques* (2° serie, tome VIII) "Sur le calcul des équipollences, methode d'analyse géometrique de M. Bellavitis" witnesses of the attention shown by the European scientific community to the *Rivista di Giornali*. The author describes the methods of the *equipollenze*, and quotes from *Rivista di Giornali* intending to report on some research by Bellavitis in the following issues of the *Nouvelles Annales*.

A more extensively research has been developed where we try to reconstruct the map of the diffusion of the *Rivista* in the most important European Universities and research centres. As for a first overview we can list the cities and the libraries where some or all the issues of the *Rivista* have been registered:

Innsbruck (Universitaätsbibliothek), Wien (Östtereichische Akademie der Wissenschaften, Bibliothek), Paris (Bibliothèque Nationale de France), Paris (Bibliothèque de la Sorbonne), Edinburgh (National Library of Scotland), London (The British Library), Berlin (Staatbibliothek zu Berlin), Braunschweig (Universitaätsbibliothek), Dresden (Sachsische Landesbibliothek-Staats-und Universitaätsbibliothek), Düsseldorf (Universitaäts-und Landesbibliothek), Göttingen (Niedersächsische Staat-und Universitaätsbibliothek), Halle/Saale (Universitäts-und Landesbibliothek Sachsen-Anhalt/Zentrale), Heidelberg (Universitaätsbibliothek), Leipzig (Universitaätsbibliothek "Biblioteca Albertina"), München (Universitaätsbibliothek), Resengurg (Universitaätsbibliothek), Passau (Staatliche Bibliothek).

A more detailed account of the diffusion of this periodical will be available in further articles.

THE INSTITUTIONALIZATION OF APPLIED BIOLOGICAL RESEARCH IN RUSSIA: BIOLOGY AT ST. PETERSBURG

Eduard I. KOLCHINSKY
Institute for the History of Science and Technology, Russian Academy of Sciences –St. Petersburg Branch, RUSSIA
ekolchinsky@yandex.ru

Abstract

Conventionally, the establishment of the V.I. Lenin All-Union Academy of Agricultural Sciences (the VASKhNIL) in 1929 has been considered as an outcome of rapid institutionalization of biological research in line with the Bolsheviks' agenda. In reality, scholars themselves initiated and supported the process using Bolshevik authorities in order to implement their own vision of the advancement of science in Russia. The foundation of VASKhNIL was not the beginning but the result of almost a century-long process of institutionalization of applied research in biology that began in 1837 inside the Ministry of State Domains. The Ministry was active in promoting new methods of land cultivation and rational use of natural resources. Under the aegis of the Ministry various academic committees and commissions were established that included agronomists, cattle breeders, ichthyologists, soil scientists, entomologists on their boards. When in 1894 the Ministry of State Domains was reorganized into the Ministry of Agriculture and State Domains, its Academic Committee defined the research agenda, planned and supervised research in the fields of agriculture and management of biological and water resources. The Academic Committee set up agricultural laboratories and experimental stations, and outlined their research programs and instructions. There were even plans for establishing the Central Institute of Agronomy, however in practice its academic and administrative tasks were divided among various bureaus affiliated with the Academic Committee (for entomology, applied biology, zootechnology, soil science, zoology of fur-bearing animals and marketable fish, etc) and created in 1894-1899. In 1901 an Academic Commission was established at the Academic Committee, which was concerned with organizing agricultural research institutions, experimental studies in agriculture and seed-farming. It was these bodies (bureaus and the Academic Commission) that eventually became the foundation for the future institutes of the VASKhNIL with Nikolai I. Vavilov serving as its first president.

Introduction

It was previously assumed that the fields of applied and fundamental research in pre-Revolutionary Russia were separated by institutional barriers; different scholars were involved in carrying out projects in these areas. Fundamental research was advanced first and foremost at the Imperial Academy of Sciences and the St. Petersburg University, whereas applied research was pursued by various governmental agencies and ministries. Therefore historians have usually claimed that intensive institutionalization of applied biological research in St. Petersburg (Leningrad) began after the 1917 Revolution and was caused by the Soviet government urging scientists to address practical problems. Subsequently a rapid growth of research institutions in agricultural sciences became one of the reasons for the rise of Lysenkoism in the 1930s. However recent studies have changed our understanding of these processes. In this year a research project ‘Biology at St. Petersburg: an encyclopedic dictionary’ has been completed.[1] It contains around 1 700 entries on various institutions (academies, research institutes, universities, experimental stations, laboratories, museums, learned societies, periodicals etc.), which have been concerned with biological and biomedical research, i.e. with life sciences. Also it contains entries on prominent scientists who made substantial contributions to the advancement of biology, to the exploration, conservation and protection of biological resources in Russia, and to the development of agriculture. Some of these entries were already published earlier in “*Biology at St. Petersburg, 1703-2010*” (2007) and “*Medicine at St. Petersburg, 1703-2008*” (2008).[2] The interaction of applied and fundamental research in the fields of agriculture and medicine in Russia, and in St. Petersburg in particular, has been recently examined in a number of publications.[3] These studies have contributed to a better understanding of the complexity and contradictions in the establishment and development of biological, medical and agricultural sciences in St. Petersburg; they have enabled us to correct many misconceived ideas about the history of institutionalization of these disciplines in Russia.

In this paper I will try to argue: 1) From the early days of biological research in Russia applied and fundamental problems were closely interrelated; 2) The institutionalization of biomedical and agricultural sciences in Russia began in the middle of the 18th century and was particularly intensive in the late 19th - early 20th centuries; 3) The establishment of the All-Union Academy for Agricultural Sciences (VASKhNIL) was not the beginning but the final phase in a long process of institutionalization of applied biological research; 4) Mass repressions of 1930s-1940s and the endorsement given to Lysenkoism by the Soviet government in the 1950s-1960s exercised a profound impact on biological, agricultural and medical research in Russia.

Original unity of fundamental and applied knowledge

The establishment of the Academy of Sciences at St. Petersburg in 1724 became an important element in the radical transformation of the country carried out by Peter the Great in the early 18th century. The reforms were necessitated by economic demands, the need to promote industrial development and popular education, modernize agriculture, and strengthen the Russian state, its international position and its potential for defence. The importation of science to Russia became an important part of the country’s modernization, which was initiated from above.[4] It is not by chance that it was arts and not sciences, which were mentioned first in the Peter I’s Decree of February 28, 1724, on the establishment of the Academy of Arts and Sciences (*Akademiia, ili sotsietet khudozhestv i nauk*).[5] From its early days science in Russia was seen as the ruler’s business, therefore it became a national tradition to give priority to applied knowledge. A disposition for collective projects was also a part of the same tradition; this tendency particularly manifested itself in expeditions organized and carried out by the Academy of Sciences in the 18th century.

Vast territories of the Russian empire could be explored only by expeditions; the scale of these voyages was unprecedented. For about two centuries scholars employed by the Academy of Sciences were engaged in the exploration of Russia’s natural resources and biodiversity. These expeditions encompassed vast territories of the Russian empire, from the Baltic Sea to the Pacific, from the Polar areas to the southern frontiers.[6] They helped to establish a strong connection between fundamental science and the needs of the Russian state. The early works produced by Russian naturalists Johann Gmelin, Georg Steller, Stepan Krasheninnikov, Peter Pallas, Ivan Lepekhin already provided information, which was extremely valuable not only for the advancement of science but also for pragmatic reasons: they described various species

of animals and plants as biological resources, and considered their potential for economic exploitation, such as fishing and hunting.[7]

Scientists, who worked for the Academy of Sciences at the Kunstkammer and the botanical gardens on Aptekarskii and Vasil'evskii Islands in St. Petersburg, carried out research on the introduction of new species of plants, which were transported from afar by exploratory missions and could be used in medicine or in various industries. They experimented with species hybridization, studied anatomy and embryology trying to find out the causes of deformity and abnormal development.[8] Later, as a rule, the members of the Academy were called to serve on various advisory boards of the state administration; they consulted the government on issues concerning economic affairs, carried out governmental assignments, took part in the training of experts on the country's biological resources, flora and fauna, agriculture and forestry, soil science, hunting and fishery, medicine, etc.[9]

Side by side with the Academy of Science emerged other centres of biological research. "Hospital schools" trained not only physicians but prominent anatomists, physiologists and microbiologists (Daniil S. Samoilovich, Martyn M. Terekhovskii, Alexander M. Shumlianskii and others).[10] The "hospital schools" formed the foundations for the Main Medical School (1786), which was transformed into the Medical-Surgical Academy in 1789. The school provided its students with sound general knowledge of biology. Many famous biologists, such as the anatomists Piotr A. Zagorskii and Vladimir N. Tonkov; zoologists Johann F. von Brandt, Nikolai A. Kholodkovskii; physiologists Ivan M. Sechenov, Ivan P. Pavlov, Vladimir M. Bekhterev; biochemist Alexander Ya. Danilevskii; palaeontologist Karl E. von Eichwald; worked for this school.[11] In the 19th century a number of new schools and research centres were established: the Clinical Institute (1885), the Institute of Experimental Medicine (1890), the Piotr Lesgaft Biological Laboratory (1893), the Women's Medical Institute (1897), the Veterinary and Bacteriological Laboratory (1898), the Psycho-Neurological Institute (1907), and a few others. Professors who worked at these schools and research centres tried to maintain the unity of fundamental and applied knowledge. A number of governmental agencies were directly concerned with biomedical research and were instrumental for its advancement in Russia: the Medical Chancellery and the Medical College in the 18th century, the Medical Department and Veterinary Administration at the Ministry of Interior, the Medical Department at the War Ministry in the 19th century. These bodies established their own academic councils and committees, enlisting many prominent Russian physicians and biologists as their members (James Willie, Karl E. von Baer, Viktor V. Pashutin, Evgenii V. Pelikan, Nikolai I. Pirogov, Sergei P. Botkin, Nikolai V. Sklifosovskii and others).

The institutionalization of research in forestry and agriculture

The Free Economic Society was founded in 1766; its aim was defined as the advancement of applied research (agronomy, forestry and cattle-breeding, among other areas) and its popularization.[12] The 1802 reform of the state administration entrusted the advancement of science and education to several governmental agencies. These ministries and departments established their own academic committees and academic councils responsible for education, research and administration in respective fields. Scholars who served on these committees and councils, particularly the members of the Academy of Sciences, the faculty of the Medical-Surgical Academy and the Imperial St. Petersburg University, which was founded in 1819, were engaged in reviewing various research proposals and projects; they produced reports, instructions and guidelines, served as governmental experts. For example, the Academic Committee for Forestry at the Ministry of Interior was responsible for forest conservation, improvement and the advancement of scientific forestry. In 1811 several schools of forestry were merged together laying the foundations of the Forestry Institute at St. Petersburg.[13]

With the establishment of the Ministry of State Domains (MSD) chaired by Piotr D. Kiselev, its Academic Committee emerged as the leading centre of applied biological research in forestry, agriculture, agriculture-related industries, fisheries

and hunting in Russia.[14] The MSD Academic Council supervised the introduction of new methods of land cultivation on the crown lands; it promoted scientific agriculture and rational exploitation of natural resources, disseminated scientific methods of fighting pests, etc. Many prominent agronomists, cattle-breeders, ichthyologists, soil scientists, entomologists, geologists, climatologists, and experts on game management served on the Council and its various commissions. In 1843 the Forest Department was transferred to the Ministry of the State Domains, and in 1851 the Special Commission for the Study of Fisheries at the Chudskoe Lake and the Baltic Sea was established. Later it organized the expedition of Karl Ernst von Baer and Nikolai Ya. Danilevskii, which examined the state of fisheries of the Ural and Volga, as well as fisheries and seal hunting on the White, Black, Azov and Caspian Seas and the Arctic Ocean. The Council produced four editions of the "*Economic and Statistical Atlas of European Russia*"; these were the earliest maps in Russia, which showed the distribution of soil types, climatic zones, the location of forests, and the state of agriculture in various provinces of the empire. Guidelines for the making of these maps were written by the climatologist Alexander I. Voeikov, soil scientist Vasilii V. Dokuchaev, geologist Alexander P. Karpinskii and other prominent scientists. The entomologist Fiodor P. Koeppen worked on the methods of fighting off pest insects, and the specialist in plant geography Sergei I. Korzhinskii experimented with the cultivation of various grape varieties. The Ministry supervised its own schools –among them the Petrovskaia Agricultural Academy in Moscow and the Forestry Academy in St. Petersburg–, as well as experimental and model farms and estates. In 1892 the Forestry Department organized a Special Expedition led by Vasilii V. Dokuchaev; its objective was to find out the causes and to explore the consequences of the catastrophic draught of 1891, and to propose methods of land improvement. The expedition party included soil scientists, geologists and plant geographers (Konstantin D. Glinka, Vladimir I. Vernadskii, Georgii N. Vysotskii, Piotr A. Zemiatchenskii, Gavriil I. Tanfil'ev and others).

In 1894 the Ministry of State Domains was reorganized into the Ministry of Agriculture and State Domains (MASD) chaired by Alexei S. Ermolov.[15] Its Academic Committee was transformed into an important division; it identified priority research areas in agriculture and exploitation of biological and water resources; it created and reformed research institutions and schools, established agricultural laboratories, experimental fields, provided guidelines and instructions. In 1898-1904 the Committee was chaired by Ivan A. Stebut. The Agricultural Bacteriological Laboratory was subordinated to the Committee. There were plans to establish the Central Institute of Agronomy, which would supervise all experimental fields, farms and stations. The institute would encompass the schools of land cultivation, soil science, chemistry, botany, zoology, agricultural machinery, meteorology, as well as a chemical laboratory, botany and zoology offices, etc. However these plans failed to materialize. Instead, its research and administrative functions were performed by a number of smaller research centres subordinated to the Academic Committee –the Bureau for Entomology (established in 1894, chaired by Iosif A. Porchinskii), the Bureau for Applied Botany (1894, initially chaired by Alexander F. Batalin, and later by Robert E. Regel'), the Consulting Bureau for Zootechnology (1894), the Bureau for Soil Science (1895, chaired by Nikolai M. Sibirtsev; in 1900 it was merged with the Bureau for Agronomy, which had been established in 1897 by Piotr S. Kossovich, changing its name to the Bureau for Agriculture and Soil Science), the Bureau for Meteorology (1897, chaired by Piotr I. Brounov), the Bureau for Industrial Zoology and Fisheries (1899, chaired by Oskar A. von Grimm). In 1901 the Academic Committee created its Academic Commission responsible for the establishment of research institutions in the field of agriculture, their course design, and the supervision of experimental research in agriculture and seed farming. The Ministry of Agriculture and State Domains also encompassed the Mining Department and the Mining Academic Committee, which was concerned with historical geology and palaeontology; it carried out research on fossil florae and faunae, stratigraphy, and was engaged in the exploration of industrial mineral deposits.

Social dislocations and the acceleration of institutionalization

In the period of dramatic social and political dislocations, which coincided with the first two decades of the 20th century, the Academic Committee chaired by Academician Boris B. Golitsyn began to play an even more important role.[16] In 1907 Efimii F. Liskun transformed the Bureau for Zootechnology into the first research institution for cattle-breeding. In the same year the Bureau for Mycology and Phytopathology, and the Bureau for Agricultural Machinery were established, while the Bureau for Particular Problems in Plant Cultivation was created in 1911. The Academic Committee also had its own Bureau for Education, which supervised agricultural schools, and the Commission for Agricultural Experiments. Many leading scientists, such as Ivan P. Borodin, E.F. Liskun, Nikolai I. Kuznetsov, Evgenii V. Wulf, R. E. Regel, Nikolaj A. Monteverde, K. D. Glinka, Vladimir L. Komarov, Dmitrii N. Prianishnikov, I.A. Stebut, G.I. Tanfil'ev among others, served at these bureaus, botanical gardens and experimental stations supervised by the Ministry of Agriculture.

After the February 1917 Revolution the Academic Committee for Agriculture was created at the Ministry of Agriculture; it was chaired by Vladimir I. Vernadskii, an ardent advocate of scientism and the chairman of the Commission for the Study of Russia's Productive Forces (KEPS).[17] Former bureaus were renamed to departments: 1) for agriculture and soil science; 2) for machinery research; 3) for meteorology; 4) for bacteriology; 5) for applied botany; 6) for specific problems in plant cultivation; 7) for gardening (its subsection for garden design was chaired by the future President of the Academy of Sciences of the USSR V. L. Komarov); 8) for mycology and phytopathology; 9) for zootechnology; 10) for fish-farming, fisheries and game-keeping; 11) for applied zoology and entomology, 12) for the organization of experimental research; 13) for forestry; 15) for bee-keeping and silkworm breeding; 16) bureau for agricultural education.[18] Many of these departments were at the same time an integral part of the KEPS: it strengthened the links between fundamental and applied research.

In 1922 the Academic Committee for Agriculture was transformed into the State Institute of Experimental Agronomy, headed by Nikolai I. Vavilov.[19] The Institute had units for soil science, applied botany and selection, entomology, mycology and phytopathology, zootechnology, applied ichthyology and scientific game and fisheries management, machinery research, forestry, agricultural microbiology, and a library. Soon Vavilov founded the All-Union Institute of Applied Botany and New Cultivated Plants and became its director. Later both institutes provided the foundations, on which the All-Union Academy for Agricultural Sciences (VASKhNIL) was created in 1929, with Nikolai I. Vavilov serving as its first President[20]. From its early days many members of the VASKhNIL were at the same time full members the Academy of Sciences of the USSR, among them were the leaders of fundamental biological disciplines: the geneticists N.I. Vavilov, Nikolai K. Kol'tsov, Grigorii A. Levitskii, Alexander S. Serebrovskii, the ecologist Boris A. Keller, the soil scientists Vasilii R. Williams, Nikolai M. Tulaikov, the physiologists Dmitrii N. Prianishnikov and Andrei A. Rikhter and others. They always advocated the unity of fundamental and applied research.

Soon Vavilov was compelled to engage in the struggle against Trofim D. Lysenko. Hundreds of selectionists, geneticists, agronomists, plant cultivators, cattle-breeders, soil scientists, foresters and other highly qualified specialists, who had begun their career in the late 19th - early decades of the 20th century, were subjected to political repressions and persecuted. Vavilov and many of his colleagues died in Stalinist prisons. Their extermination in the years of the "Great Terror" ensured the victory of Lysenkoism in the USSR, where it enjoyed absolute dominance in the 1930s-1970s. Many of its advocates are still influential in the applied branches of biology: their leverage accounts for the production of books denigrating Nikolai I. Vavilov and other victims of the Stalinist terror, while glorifying Lysenko and his 'achievements'.[21] These books are published in a massive number of copies.

Conclusions

The institutionalization of applied biological research was under way from the very moment when science was imported to Russia. Many scientists and science administrators took part in this process. The system of research institutions, which emerged in the late 19th - early 20th centuries within the administrative structure of the Russian government, became the basis for the making of institutional infrastructure for agricultural research in the USSR. The VASKhNIL was established upon the initiative of scholars, who after the 1917 Revolution used the Bolsheviks to promote their own pre-Revolutionary designs for a broad network of research institutes in Russia.

The structure of the pre-revolutionary research institutions survived the regime change and became the matrix for the new institutes –the VIR (the All-Russia Institute for Plant Cultivation), the VIZR (the All-Russia Institute for Plant Protection), the Institute of Forest Management, the GosNIORKh (the State Research Institute for Protection of Lake and River Fisheries)–, or they became a part of these institutions as laboratories, bureaus, departments, experimental stations, etc. Many of these institutions considered fundamental research as the basis for solving applied problems.

THE ACADEMY OF SCIENCES EXPEDITIONS OF THE FIRST HALF OF THE 19TH CENTURY AND THE DEVELOPMENT OF PRACTICAL BIOLOGY IN THE RUSSIAN EMPIRE

Tatiana Yu. FEKLOVA
Institute for the History of Science and Technology, Russian Academy of Sciences –St. Petersburg Branch, RUSSIA
telauan@rambler.ru

Abstract

The first half of the19th century is for the whole world the period of formation of the capitalist relations. At this time Russian science has reached a new stage in its development. Industrial development also puts other purposes and problems before science. The 18th century was a time when the enormous territories of the Russian empire had practically not been studied yet, nor was any finding considered of interest. The problems of a more purposeful approach to research had been put before scientists. Expeditions were an integral part of the Academy activity for promoting its further development and prosperity. They helped to create a data-base for the future development of science.

First of all, expeditions gave wide opportunities for carrying out various researches in the fields of geography, biology, zoology, ethnography, etc. Secondly, expeditions allowed for the improvement of scientific methods. Along the travel, scientists developed their own techniques and methodologies for research, which, after its completion, could subsequently enter into a scientific arsenal.

From the total number of analyzed expeditions (41 expeditions made by the Academy of Sciences, either separately or together with the ministries), 15 led to appreciable breaks in science – of which 7 especially in biology.

Since the first years of existence of the St.-Petersburg Academy of Sciences (1724), expeditions were an integral part of its activity. Through a studying prism of expeditions, we can to retrace the history of development of the outlying districts of the empire, the change in cultural and public life in the country, the growth of consciousness by national minorities.

In the first half of the 19th century across the Russian empire 28 expeditions took place. Outside of empire there were 15 expeditions. From all of them, only 16 were biological expeditions. But almost all expeditions during that time were complex. Scientists going in ethnographic or geological expeditions received numerous instructions concerning biology. According to these instructions, those scientists collected herbariums and made biological observations. Not only have expeditions enriched the academic science with up-to-date materials, but also were given the chance to receive trustworthy information about the nature and population of the Russian empire. Scientific fundamental and applied research methods and a technique for collection gathering were developed and improved during the expeditions. Many of those methods have reached up to now. Expeditions also promoted not only botanizing, but also the development of sciences as a whole, and its separate areas.

From all the variety of expeditions promoting the development of practical biology in the first half of the 19^{th} century, we have chosen the most representative ones, such as Baer's expedition to Nowaja Zemlya in 1837, Middendorf's expedition across Eastern Siberia in 1842-1845 and Shrenk's expedition on the Russian Far East in 1853-1856.

K. M. Baer's expedition to Nowaja Zemlja in 1837

Baer's expedition to Nowaja Zemlya in 1837 was one of the basic stages in studying the Russian North. It begun in May 1837, and its main aims were:

1. Botanical, zoological and geological investigation in the Nowaja Zemlya archipelago.
2. To collect botanical and zoological samples.
3. To make more precise geography maps.

Karl Baer was in expedition with his colleagues:

1. Student of the University of Derpt A. A. Leman.
2. Laboratory assistant of the Zoological museum E. Filippov.
3. Painter H.R. Reder.
4. Attendant Dronov.

In 6 of July 1837, K. M. Baer arrived at Archangelsk. On 19 July the explorers had reached the shores of Nowaja Zemlya. Until 21 August the scientists worked on Nowaja Zemlya. In October K.M. Baer arrived with his companions at Saint-Petersburg.

K. M. Baer's complex research allowed putting a base for Nowaja Zemlya's climatology. Nowaja Zemlya had been investigated topographical, geological and zoological relations. This expedition gave the basic file of knowledge of this region that we have now. Baer's expedition to Nowaja Zemlya represents the first attempt of approach to a modern complex ecologic-biological method for studying territories. K. M. Baer collected 135 plants of the total amount of species, 197, which are growing in Nowaja Zemlya.

A. F. Middendorf's expedition to Eastern Siberia in 1842-1845

Middendorf's expedition in 1842-1845 had a huge value for research of Eastern Siberia. The main aims of the expedition were:

1. To find out the deposit conditions for permafrost.
2. Botanical, zoological, physical and geographical investigations in the region between Turuchansk and river Khatanga.
3. To study the quality and quantity of organic life on the Far North, far from the sea coast.

Companions:

1. Topographer V.V. Vaganov.
2. Forest guard T. Brandt.
3. Laboratory assistant M. Furman.

In January 1843 A. F. Middendorf arrived from Krasnoyarsk in Turuhansk. On 25 February 1843 the researcher arrived at Turuhansk. On 12 August 1843 A. F. Middendorf reached the Taymyr peninsula. In a year on August (1844), the explorer swam in the Okhotsk sea, and only on 20 March did he arrive at Saint-Petersburg.

A. F. Middendorf was the first researcher of such a scientific phenomenon as permafrost. He was the first to collect numerous data about nature and environment of theTaymyr peninsula and the Priamursky region. He opened the Byrranga and Bureinsky mountains ridges. In reports of Middendorf's expedition, the complex characteristics of the nature of the surveyed territory are given. These reports considered detailed data on climate, vegetation and fauna of Siberia.

A. F. Middendorf offered the first scientifically well-founded scheme of ecologic-faunistic division into the districts north and east of Siberia, and in details considered a problem for modern distribution of animals. Middendorf's investigation was very important for practical biology, for example Middendorf defined the borders of various botanical-geographical zones of vegetation.

L. I. Shrenk' expedition to the Russian Far East in 1853-1855.

The expedition of L. I. Shrenk to the Russian Far East in 1853-1856 laid the basis for such a synthetic science as zoogeography. The main aims of the expedition of 1853-1857 were:

1. Botanical, zoological and geographical investigation.
2. To collect the botanical and zoological samples.
3. Investigation of meteorological phenomenon, sea ebbs and high tides.
4. Astronomical definition of a geographical position of the main points of the visited countries.

Companions:

1. Painter V. Polivanov.
2. Laboratory assistant M. Shil.

In 1853 L. I. Shrenk leaved Saint-Petersburg. In the beginning of August 1854 L. I. Shrenk reached the Nikolayev post (the coast of Okhotsk sea) with his companions, and there he founded a storehouse for the investigations. During the long autumn and winter time, they investigated the surroundings of the post and the coast of Sakhalin island.

In the spring of 1855 L. I. Shrenk, together with the other members of the expedition, went by boat upwards on the Amur. In January 1857 L. I. Shrenk arrived to Saint-Petersburg.

L. I. Shrenk, as well as K. M. Baer, suggested considering nature not as an assortment of separate species, but as a complex in which an important role was played not only by animals and plants, but also by geographical and climatic conditions. Accordingly, the studying of separate species was not possible without studying the conditions of their formation, origin and existence.

Also for the first time the researcher revealed and defined such signs of species as their morphological structure and the presence in a definite area. On the basis of such approach, the academician created the zoogeography of the Priamurja region and conducted the biooceanographic research of the Russian seas (especially the Japanese Sea). Shrenk was the first scientist to apply the method of local flora investigation. It was very important for the development of practical biology.

Conclusion

Science differentiation has now practically reached its apogee, but initial division of sciences had begun in the first half of the 19th century. During long-term expeditions, the methods which have subsequently become the basic ways of materials collecting, appeared and fulfilled. Collected data, after their processing and analysis, led to the occurrence of new branches of science, including biology. Thus, expeditions were the areas on which new methods were tested. Russian scientists, in extreme conditions, using imperfect tools, conducted unique researches promoting progress and development of domestic science.

ZEMSTVOS AND NATURALISTS: OBJECTIVES OF APPLIED RESEARCH, METHODS OF FUNDAMENTAL SCIENCE

Anastasia A. FEDOTOVA
Institute for the History of Science and Technology, Russian Academy of Sciences –St. Petersburg Branch, RUSSIA
f.anastasia.spb@gmail.com

Abstract

In their recent works, historians of Russian science emphasise that many projects which were carried out in the field of natural history in the European Russia in the late 19th century, with funding provided by local elected authorities (the zemstvos), could be defined as applied research only in terms of their objectives, but not their methods and results. For example, Vasilii V. Dokuchaev's expeditions to Nizhnii Novgorod and Poltava provinces were very important for genetic soil science; however, they failed to achieve their explicit practical goal of cadastral surveying. In my paper I attempt to analyse some reasons accounting for this tendency.
In the 19th century many Russian naturalists and agronomists sought to prove that the study of local nature was essential for the advancement of agriculture. In my view, their views were a reaction not only to a primitive state of agricultural production in the country but also to the failures in a 'blind' transfer of Western European practices. European education in agrology, as well as European literature in that field proved to be insufficient for transforming rural economy into successful agricultural enterprise. At the same time the tsarist government still refused to acknowledge that agriculture required specialised knowledge. When in the last two decades of the 19th century scientists began to study local natural environments, they were very excited about these projects, as they were convinced that the study of natural history was the first step towards rationalising agricultural production in Russia, while they never questioned their own research design: they did not consider the need to change their methods and research objectives. Many of these projects pursued applied objectives but employed methods borrowed from fundamental science. Therefore their results contributed primarily to the advancement of fundamental science. Thus in the late 19th century we observe a conspicuous gap between primitive methods of agricultural production and advanced state of research that was hardly relevant for everyday agricultural management.

It has been a common place in the history of Russian science to claim that many studies produced by 'outstanding Russian naturalists' were directly linked to the applied problems. Recently some historians have emphasized almost the opposite trend: they claim that many naturalists' studies in the European part of Russia in the late 19th century that were funded by local authorities (the *zemstvos*) can be called 'applied' only if we consider their problems but not their methods and their results. The expedition of Vasily V. Dokuchaev and his team to the Nizhegorodskaya (1882-1886) and Poltavskaya (1888-1894) governments[1] are examples of such phenomena.

In the introduction to the 14-volume "Materials" of Nizhegorodskaya expedition Vasily Dokuchaev[2] declared that one of the reasons why he had accepted the proposal made by the Nizhegorodskoye zemstvo was the urgency of the problem: the aim of the project was to work out a system of land assessment that would ensure fair taxation. However the project output turned out to be a very important contribution to soil science and plant geography –it was not particularly helpful in terms of land assessment.

Materials of Nizhegorodskaya and Poltavskaya expeditions and similar works[3] contained standard descriptions of surveyed territories, as they were conducted by naturalists. Plant geographers focused mainly on natural plant communities, soil scientists concentrated on uncultivated soils. Such objects were interesting for naturalists but not for farmers. The research methods of Dokuchaev team were methods of pure science, and Vasily Dokuchaev regularly stressed this point. Dokuchaev himself, his team and followers were more interested in pure knowledge: how would their principles of classification soils or plant communities work? Were the principles of ‘genetic’ classification of soils, which they had developed in Nizhegorodskaya expedition, applicable to other regions and to other soil types? Dokuchaev and his followers were much less concerned with immediate practical value of their research for local authorities or farmers.[4]

I am not claiming here that scientists consciously ignored practical questions they were commissioned to solve or had cynical intention to ‘satisfy their curiosity at the expense of the state’ (or in this case at the expense of the zemstvos or local landowners, since Dokuchaev’s team also surveyed private estates[5]). I agree with Alexey Karimov[6] when he suggests that Russian naturalists merely assumed: when a thorough academic research was completed its results would immediately answer pragmatic needs of agricultural practice, in other words, their utility would be self-evident.

Throughout the 19th century, Russian naturalists, public figures and agriculturists tried to convince the government that the study of local nature was the first step to make in order to improve backward Russian agriculture. I believe that this attitude was a reaction not only to the backwardness of Russian rural economy, but also to unsuccessful transfer of the European agronomical technologies.

In the 19th century, agriculture as a field of knowledge was still not a scientific discipline but a set of ‘recipes’. In some European countries agricultural technology was relatively advanced but in most cases it was just a collection of good practices accumulated by generations of peasants and farmers by trial and error. Like any other recipes, these rules produced by agricultural practice prescribed what was to be done but usually did not explain why it had to be done in a particular way. Explanations appeared only in the second half of the 19th century with the development of plant physiology, organic chemistry, biochemistry, and other disciplines.

When Russian landowners tried to copy technologies developed in Western or Central Europe, the results were most often unsuccessful. The reasons for these failures were understandable: different environment conditions required the technologies to be modified in order to match different environment.[7] Consequently, in order to adapt European technologies to Russian environment it was necessary to study the environmental conditions of a particular province.

[3] There we can include not only the expeditions of V.V. Dokuchaev and of his direct disciples, but also some others researchers, for example the surveys produced by the Kazan naturalists A.Ya. Gordyagin and R.V. Rizopolozhensky sponsored by the Kazan Naturalists Society and by the Kazan Provincial Zemstvo in 1888-1890.

[4] Perhaps only one participant of Dokuchaev’s Nizhny Novgorod expedition –N.M. Sibirtsev– seriously collected information on the tillage methods, yields, frequency of crop failures and droughts etc. Later, Sibrtsev stayed to work in the Nizhny Novgorod as a head of the Natural History Museum of Nizhny Novgorod Provincial Zemstvo. Working with Statistical Department of the Zemstvo he discussed the minimum of necessary soil studies for the land cadastre.

[5] For example, Narishkin’s estate “Pady” in Saratov province, Shuvalov’s estate in Voronezh province etc.

Everyone would agree on that: all problems began later. The Russian government acknowledged that the level of agricultural technology in Russia was considerably lower than in Europe. But it had no long-term policy on this matter.[8] From time to time the government made convulsive attempts to improve the situation: it imported technology, together with their carriers (for example, with German colonists), established the chairs of agriculture at the Russian universities, etc. However if we consider the chairs of 'rural economics' at the Russian universities we have to admit that it was only in Dorpat where agriculture was more or less successfully taught before 1840s. In other universities attempts to introduce courses on agriculture failed. Thus, Karl A. Nöldechen (1771 (1772?)-1819), who was the first Professor of rural economics at the Kharkov University (1811-18), turned out to be so inept in this position[9] that after his dismissal the University Council lost any interest in the subject itself and the chair remained vacant for more than twenty years. From time to time some other professors gave lectures on 'rural economics'.[10] Before 1865, when the Petrovskaya Academy of Agriculture and Forestry (nowadays the Timiryazev Agricultural University in Moscow) was created, Russia had no institution of higher education for agriculture; the only exception was a small Agricultural Institute in Gori-Gorky (in present-day Belarus) founded in 1842. A catastrophic shortage of specialists, agronomic training and, especially, research institutions existed until the first decades of the 20th century.

Those few landowners and managers who were trying to improve their estates and farmsteads got no support. Even if by trial and error they discovered a relatively good 'recipe', there was no structure –state, public or commercial– that could help them to promote and improve their practices. The situation did not change until the late 19th century when first agricultural experimental stations appeared in the Russian Empire.

In the 19th century Russia, with its primitive state of agricultural knowledge, 'progressive' public figures, landowners and agronomists respected scientific knowledge very much and expected benefits, which it would bring to agriculture. Under benefits they understood not only increased incomes but other things as well. Russian 'educated public' believed that as soon as local nature of their provinces would be described by scientists, academic research would immediately provide them with exact guidelines, which would enable them to get higher and stable yields without depleting soil and damaging nature; in other words, academic research would furnish them with a recipe for "sustainable development", if we apply modern terminology.

I give a couple of examples to prove these arguments. Firstly, I quote an opinion expressed by Alexander Izmailsky. Alexander Ismailsky (1951-1914) was an agronomist, who graduated from the Petrovskaya Academy. Most of his life he served as a manager on large estates in the Russian steppe provinces. He conducted several series of experiments on measuring soil moisture in different environmental conditions. His experiments and publications proved to be a valuable and timely contribution to research produced by Dokuchaev and his team.[11]

In December 1892 the Moscow Agricultural Society discussed an idea of organizing 'public works for irrigation of Southern and Eastern Russia'.[12] In his letter to Dokuchaev Izmailsky discussed this project and expressed his doubts: "what could be more logical (considering our poverty): to spend money on irrigation and afforestation of tiny plots, or on a broad survey of all environmental conditions of the Russian steppes?"[13] Alexander Ismailsky obviously supported not these small-scale experiments with their practical local implications, but fundamental science.

Another episode. In 1897, the Statistical Committee of the Free Economic Society upon the request of the Russian government discussed the best ways of assessing land value. V.V. Dokuchaev advocated his own approach based on his experience of surveying Nizhny Novgorod and Poltava provinces. In his view, a cadastral survey should start with determining 'natural characteristics of arable land on the basis of its geological, chemical, botanical and zoological characteristics, as well as their links to climate'[14]. This part should be carried out by specialists in soil science without any participation of local population. Only at the second stage of a survey, when local economy is examined, local population should be consulted. In fact, Dokuchaev's program promoted the interests of fundamental science and the governmental

agencies, which accumulate the data on the whole empire collected on the basis of a uniform methodology, and not the interests of local authorities and landowners in the provinces.

Defending the advantages of scientific approach, as compared to the methods of statistical research, V.V. Dokuchaev was unwilling to accept its limitations and made gross mistakes when he discussed economic issues. Judging from his experience of studying soils in Nizhny Novgorod and Poltava provinces, V.V. Dokuchaev suggested that a cadastral survey had to focus on what he called 'natural productivity' of soils. But Dokuchaev's concept of 'natural productivity', which Dokuchaev extrapolated from physical and chemical characteristics of soil, was very poorly related to the actual fertility of soils. Dokuchaev team conducted no experiments to assess soil fertility. A comparison of actual yields produced on different soils did not confirm Docuchaev's assessment.[15]

Statisticians from the Free Economic Society criticized Dokuchaev's program as serving the interests of the central government rather than those of local zemstvos and landowners.[16] But Dokuchaev's team, probably, was convinced that their long-term interests (working out a uniform, universally applicable method for a comprehensive description of natural resources in different regions of the Russian Empire) were more important than the short-term zemstvo interests (working out guidelines for land value assessment and cadastral surveys). This interest in developing a single standard universally applicable method for a comprehensive description of natural resources became a permanent feature of Russian soil science and plant geography in the 20th century. Which one of several terms is the most appropriate? What is the best scale to use? Which method should become the standard one for describing a plant community in any region of the country? Of course, standardization of research methods was necessary to achieve some progress. However in the Soviet era this emphasis on uniform methodology did a bad service to Russian plant geography and soil science.

Conclusion

In the last quarter of the 19th century Russian naturalists began to work together with local authorities on their projects, which were aimed at the exploration of natural resources. Both parties evidently hoped that their research would equally benefit local agriculture and fundamental science. However when scientists began to work on these projects commissioned by local authorities, they focused on their own research agenda, which was of little or no relevance for practical problems. Scientists produced knowledge, which was not immediately applicable for the needs of domestic agriculture. The sphere of applied research, which mediates between these two extremes – fundamental science and local knowledge, had not yet been created. In the last quarter of the 19th century soil scientists and plant geographers only claimed that their research was of an immediate value for practical purposes. Real cooperation between scientists and local authorities began later – at the turn of 19th and 20th century when first agricultural experimental stations were created, and zemstvos established permanent salaried positions for experts in natural sciences. But even in the early decades of 20th century we could observe a huge gap between the achievements of fundamental science (soil science, plant geography and so on) and a primitive level of agricultural technology in the country.

Abstract

Since the 1870's, Darwin's theory has been disseminated among intellectuals and scientists in Brazil. The capital city of Rio de Janeiro, just as other capitals in the world, was re-urbanized in the beginning of the 20th century inspired by the reform of Hausmann in Paris. Behind the process of modernizing the city was the initiative of sanitizing the Brazilian capital, what was undertaken under the coordination of the hygienist Dr. Oswaldo Cruz. Among intellectuals, Euclides da Cunha, a military who followed positivist orientation and was adept to Darwin's theory, based his main publication Os Sertões (The backlands) on the interpretation of Darwin's ideas. The book describes the struggle in the hinterland of the country between a group that supported the imperial government and the troops of the newly installed Republican army. The publication praises both the natural settings and the toughness of the hinterland man, contrasting him with the polite but weak urban men, more susceptible to diseases. Literature and urban architecture applied the scientific precepts of Darwinism in order to solve social, political and cultural issues of the city and the country.

Introduction

Our analysis focuses on the theory of evolution in the early 20th century, addressing the racial question central to natural and social sciences, which led to urban intellectual and social problems as manifested in the arts and popular literature.

With the end of slavery in the late 19th century, cities in Brazil were confronted with an exodus of former slaves from the hinterland. At the same time, waves of European immigrants were arriving in the country. It was at that moment that racial issues started to emerge as a fundamental question. In the early 20th century, the racial question as discussed in Brazil and many other countries was imbued with the theory of eugenics, which was seen as a science for the improvement of human heredity, leading to the popularization of eugenicist ideas (Seyferth, 2008: 148).

Our discussion compares Darwinist interpretations of the question of human race as expressed in science, art, and literature. At the beginning of the 20th century, the subject of race gained enormous prominence in Brazil, soon after Euclides da Cunha had published the novel *Os Sertões* (translated into English as *Rebellion in the Backlands*) in Rio de Janeiro in

1902, to great acclaim. Constantly recovered, Euclides da Cunha has become a mythical figure in Brazilian literature.[1] In the 1920s, the Modernist Art Movement emerged in São Paulo, with the mixing of races in Brazil as one of its main themes. This movement also adopted the work of Euclides da Cunha. The confrontation of such different intellectual and cultural productions constitutes the core of the discussions in this work.

A few studies on the racial question have drawn attention to the involvement of politics in the science of the topic, which characterized the first part of the 20th century. According to Chris Manias, race and national types divided the supporters of European Aryanism. The Germans proclaimed themselves a nation based on the idea of the white race, whereas the French rejected the idea that nation and race were linked and claimed diversity in their historical origin (Manias, 2009: 733-757). While in Europe the racial question was linked to differences between ethnic groups, in the United States, a country with a slave tradition, the problem was the discrimination against blacks by whites, against which Einstein was one of those who protested. Speaking at Lincoln University in 1946, he pronounced the famous sentence: “The separation of races is not a disease of coloured people but a disease of white people. I do not intend to be quiet about it”(Jerome, 2004: 628).

Although Brazil also had a tradition of slavery, the racial question there took the form of miscegenation and involved all sectors of society: intellectual, scientific and political. For human sciences in general, in the first decades of the 20th century, race meant eugenics; however, interpretations were not homogeneous. These issues appeared during the First Brazilian Congress of Eugenics, organized by the anthropologist Roquette Pinto, of the Museu Nacional in 1929. For Nancy Stepan, the existence of both a soft and a hard form of eugenics in Brazil within the neo-Lamarckian tradition and the opposition that developed between the neo-Lamarckian racialists and the Mendelian anti-racialists suggested that the inherent logic of science does not determine its social meanings and outcomes (Stepan, 1990: 145).

Race, man and environment in literature

The determinism of man and environment according to evolutionist ideas appeared in Euclides da Cunha’s book *Os Sertões*. The author emphasizes that the book was based on the theory of evolution and, in fact, he uses expressions such as “struggle for life”, “adaptation” and even a neologism in Portuguese: “*mutuar*” (to mutualize) –implying mutual exchanges, in this case between what he called physical (subject to genetic action) and geological (stable) agents– to define the backlands and their inhabitants, demonstrating his knowledge of Darwinian theory[2]. However, while emphasizing determinism in the environment, he mentions Buckle and does not hide his appreciation for that positivist intellectual who praised the powerful action of the environment on society.[3]

Os Sertões tells the saga of the struggle of a group of backlanders (inhabitants of the remote inland area of north-eastern Brazil) against the forces of the newly founded Republican government, which had replaced the Monarchy which had governed the country since its independence in 1822. The group was led by Antonio Conselheiro, a mythical figure whose image is still considered holy today. What is relevant about this work is not really the history of the fight between the group and the army, but, the image which Euclides da Cunha depicts of those backlanders, who gained strength in the “struggle for survival against an inhospitable environment, of dry land in the winter and fertile in the lush summers”, which he describes perfectly. For Euclides da Cunha, the backlanders are descendants of the white men who ventured into the hinterland (*bandeirantes*) and Indians, and he concludes that “the inferior race reacted positively on the superior one”, becoming a symbol of Brazilian nationality or, in the language of the time, “the race” that characterizes Brazil.

Euclides da Cunha’s description of the landscape is magnificent. The impotent land has a tormented appearance, scorched by “external agents”, with stupendous relief and a stunted flora resulting from the climate of torrential rains following long periods of relentless sun. The land is subject to forces which act silently during the only two seasons in the region, causing molecular imbalance. On the almost naked hills and in contorted dry river beds, the flora is a tangle of branches in a representation of the land’s martyrdom. In the alternation of days and nights, the land suffers from the extreme dryness of the air and faces sudden changes in temperature, adding the martyrdom of dilations and contractions, an alternation that becomes worse when the rain falls and closes the cycle of drought.

In an evolutionist view, Cunha states that the incipient region is still preparing for life because lichen still attacks the rock, fertilizing the earth, and a flora of rare resistance tenaciously struggles against the scourging climate.

---

[1] See Candido, 2006; Santana, 1999; Martins, 2001; Abreu, 2006; Sousa and Galvão, 2007. In the 1920s, Euclides da Cunha was honored by the anthropologist Roquette Pinto, who named a room in the National Museum of Natural History in his honor. Lima (1999) draws attention to the new intellectual interest in the backlands in the early 20th century.

[2] See Souza, Vanderlei, 2010.

[3] According to Kaat Wils, Buckle, whose ideas were influential in Brazil, was a staunch Comtian positivist historian who believed that civilization was the result of the development of empirical knowledge. His positivist beliefs were seen as being closely related to Marx’s historical materialism (Wils, 1999).

He describes the drought as an intolerable intermittence of extremely hot days and freezing nights: "The naked earth having counterposed in permanent conflict the emitting and absorbing capacity of the materials that form it ... is seared by the sun and absorbs its rays, and multiplies, reflects and refract them in a dazzling reverberation, in which the leafless branches of the defeated flora collapse" (Cunha, 1927: 28).

The flora of the *caatinga* (a dry forest ecosystem of the semiarid region of northeast Brazil) smothers man and subdues him as it spreads over the land in spiny foliage, which explains the original account of the "struggle for life" in the backlands.

Fig. 1: Caatinga: a dry forest ecosystem of the semiarid region of northeast Brazil.

The inhabitant of the backlands is a *mestizo*, or a mix of the white men who set off to explore the interior –the *bandeirantes*– and ended up staying there, and the indigenous peoples, whom they had dominated and enslaved, but whose nature they also took advantage of. Thus the backlander's character evolved, blending the adventurous nature of the colonizer and the impulsiveness of the indigenous people, and influenced by the isolation, which forced him to react to his environment. The Indian was diluted in the backlander and this gave him intimacy with his environment, preventing him from degenerating. Reaffirming the theory of evolution, Cunha further asserts that in the hinterland the struggle for life was wild in nature, forcing people to face the horrors of the drought and the cruel battles with the arid land, compensated by the abundance that came with the return of the rainy season. "The backlander is first and foremost a strong man!" However, Cunha continues, "he is frozen in time, discarded by the general movement of human evolution. He depends on the land."

In his determinism, Euclides da Cunha does not attribute the destruction of the environment to the inferiority of the races, but he accepts polygenism, affirming that the American races are autochthonous, a common idea among anti-Darwinian anthropologists.

Euclides da Cunha's ideas were rediscovered in the 1920s by the modernist art movement in São Paulo, which reoriented the picturesque and the exotic elements of backlands literature that Euclides da Cunha did not encompass.

Anthropophagic art

The Anthropophagy Movement emerged in art and literature as an icon of Brazilian modernism breaking the chains of intellectual colonization, not through anti-Eurocentrism, but through the blending of European culture, which had shaped Brazilian intellectual life, with the cultural expressions of people from the interior of Brazil. The movement was an intensification of the well-known Brazilian modernist movement, which had burst onto the scene in the 1922 Modern Art Week (*Semana de Arte Moderna*), a week of art exhibitions and book readings and launches held in the city of São Paulo. That week marked the beginning of the *Pau-Brasil* (Brazil Wood) art movement, which was later radicalized by the Anthropophagy movement.

The contrast between the two movements is reflected in paintings by Tarsila do Amaral. In her Pau-Brasil phase, natural beauty was painted in a spontaneous, ingenuous, happy way, revealing the Brazilian landscape openly and directly, with no mystery, whereas in her Anthropophagic phase the simple, brutal, barbaric, illogical face of nature was reinforced

(Gotlib, 2003: 149), emphasizing the wild and the barbaric. The Anthropophagite Manifesto was marked by the dichotomies of town and country and of rationalism and magic (Amaral, 2006: 24).

In 1928, in São Paulo, the painter Tarsila do Amaral[4] gave her husband, Oswald de Andrade (who was a writer and one of the leaders of the literary modernist movement) a birthday gift of a painting depicting a strange figure, which they mutually agreed to name *Abaporu*. The word, taken from the Tupi language, meant "anthropophagous": *aba* –man; *poru* – one who eats human flesh. The painting shows a strange, enlarged figure, with an accentuated contrast between its enormous feet and hands and its minuscule head on top. The earthy colour of the figure contrasts with the blue sky and the blazing sun, a reminder of the baking heat of the backlands. Below, there is a lone green cactus, a characteristic plant of that region described by Euclides da Cunha.[5] Thus was created the Anthropophagy Movement.

Fig. 2: *Abaporu*.

The Anthropophagite Manifesto emphasizes the "barbaric" character of the Brazilian cannibalistic or anthropophagous "savage", capable of devouring or digesting the culture of the country's colonizers –not only the Portuguese, but also other Europeans, including all those that emigrated to Brazil, such as Germans and Italians, and also Africans and Asians (Andrade, 1995).

In the words of the literary critic Antonio Candido, the Modernist Movement in its heroic phase essentially released Brazilians from a series of historical, social and ethnic hang-ups, which were triumphantly brought to the surface of literary consciousness. Modernism adopted a philosophy which attributed a constructive, heroic meaning to the crucible of races and cultures located in a harsh environment. That was a view contrary to the colonizing attitude of the 19th century, which extolled the profusion of nature in Brazil and underestimated man, who was seen as barbaric and inferior. Modernism accentuated the rusticity, the dangers, the obstacles of tropical nature and included the *mulato* and the black man as subjects for study and inspiration. "Primitivism is now a source of beauty, and no longer an impediment to the elaboration of culture. This is true in literature, in painting, in music, in the sciences of man" (Candido, 2006: 127).

In the case of Tarsila do Amaral, it seems that Anthropophagism must already have been present in the 1922 movement, since in 1923 she painted *A Negra* (*The Black Woman*) with a refined Cubist technique and Legerian forms in a design which accentuated not only the harsh, illogical imprints with which slavery marked slaves –disproportionate breasts, which nursed the master's children, and enormous hands and feet representing the hard work in the fields– but also the

[4] Tarsila do Amaral lived in France in the early 1920s, where she studied under Fernand Léger and was introduced to the intellectual circle, developing a close relationship with the poet Oswald de Andrade.

[5] Transcending the botanical descriptions given by Euclides da Cunha, the cactus comes to be seen as a representation of backland Brazilianness. It was already being used in Brazilian garden design in the 1920s and the famous landscape gardener Burle Marx used cacti in his first projects in the 1930s (Martins, 2009: 152).

physical features of the black race –thick lips, reflecting a question which dominated the anthropological sciences at that time: the study of the races[6]. It is relevant to emphasize that those were the times of eugenics in the natural and social sciences.

In 1928, in the middle of the scientific discussion about eugenics, Tarsila do Amaral painted *Ovo* (*The Egg*), representing the life cycle, and the large serpent which, according to Amazonian legends, used to appear to demand the rescue of a damsel. The egg represented the genesis of a being that was subject to its environment, represented by the serpent surrounding it.

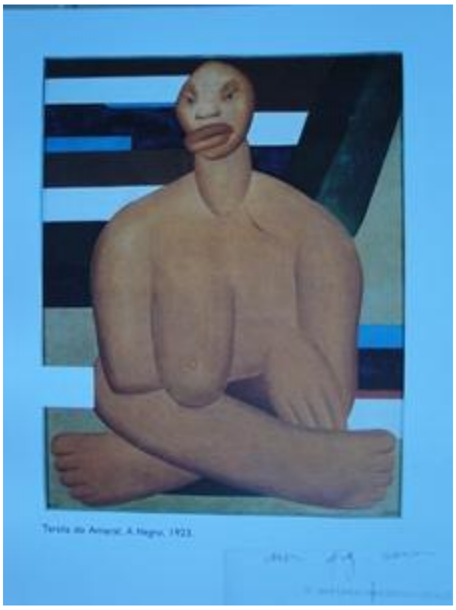

Fig. 3: *A Negra* (*The Black Woman*)

Fig. 4: *Ovo* (*The Egg*)

Soon after *Abaporu* Tarsila painted *Antropofagia*, a painting which crossed *A Negra* and *Abaporu*, "a primordial couple that originated Brazilian culture". The anthropophagy movement implicitly brought with it the issue of immigration, a subject that permeated both politics and science in that decade.

Eugenics and anthropology

In 1929, when the First Congress of Eugenics was held in Rio de Janeiro, the central subject was the immigration policy that the government was putting into practice. In the conference proceedings, Roquette Pinto stated that immigration should not be promiscuous. In his view, individuals should not be submitted to the influences of the environment to the point that their hereditary characteristics were altered; therefore, the selection of migrants had to be rigorous and had to take into account the collective attributes of different populations: their individual conditions, and the mental and moral qualities of each one, which would determine the value of the racial element, Any immigrants with a criminal background should be excluded and subsidized immigration was unacceptable, because poverty was an indication of mental and moral inferiority (Roquette Pinto, 1933:75). Racial differences were not mentioned.

Grounded in Darwinian theory, unlike some eugenicists, Roquette Pinto followed the American Jennings in concluding that heredity was nothing more than the presence of biochemical material. Each gene contains hundreds of chemical bodies which react among themselves, which makes it impossible to control them. Therefore, during development, heredity is a potential that depends on environmental conditions, which means that upbringing plays a key role. Man would be in control of his destiny if the eugenic ideal were in fact feasible: to multiply the best... But who would be the best?

As already mentioned, the question of race was one of the most important scientific issues facing the natural and human sciences at that time. In Brazil there was a belief in the "whitening" of the people, which was a continuation of a

[6] Roquette Pinto, an anthropologist at the National Museum in Rio de Janeiro, defined anthropology at the beginning of the 20th century, unlike the "old anthropology", which wasted a lot of time arguing about the origin of man and other remote subjects, as "modern anthropology", which deals with current issues: "what are the factors of race?" (Roquette Pinto, 1933: 62).

scientific view held in the 19th century. In 1895, the painter Modesto Brocos y Gomez showed his painting *Redenção de Can* (*Redemption of Ham*), which was seen as a representation of the ideology of the whitening of the Brazilian race (Schwarcz, 2003).

Fig. 5: *Redenção de Can* (*Redemption of Ham*)

In 1911, Roquette Pinto attended the First Universal Races Congress in London as assistant to the director of the National Museum, João Batista de Lacerda. During the event Lacerda presented a polemical work entitled *Sur les métis au Brésil* (*On the mestizos in Brazil*), in which he showed the influence of black people on family morals, on the social and political formation of the country, and on the gradual whitening of the Brazilian population. At the event, Lacerda announced that in one hundred years the Brazilian population would be white, based on data from the official 1872-1890 statistics of E. Roquette Pinto (Castro Faria, 1952: 22). This idea had a great impact. The debate continued throughout the 1920s and, for many eugenicists, miscegenation was seen not as a cause of degeneration, but rather of regeneration, because it led to the stabilization of the whitening of the population by natural means.

At the Eugenics Congress of 1929, the theory of natural and "social" selection became the dominant idea and ended up defining even eugenics. Most participants believed that biological crossing accompanied migratory movements, especially in countries like Brazil, where whites, blacks, and Indians lived together (Roquette Pinto, 1933). Roquette Pinto analyzed this question taking the theory of natural selection into consideration. He explained the miscegenation of races using two ideas of selection: biological and social, and he concluded, quoting from Eugen Fischer, that the characters of two races that have crossed remain side by side in the descendants, waiting for selection to prompt one of them to become dominant.

Miscegenation is *combination*. It is absurd to use the expression *a mix of races,* explained Roquette Pinto, still quoting from Fischer. As in a chemical reaction, the substances that cause it are not the same as those that result from it, nor do they retain the same properties. A selective process, he stresses in his Mendelism, is not an infinite transformer of organisms, but it is capable of taking apart phenotypes and giving prominence to genotypes. That is what was happening in Brazil.

> It is an idle and anti-scientific concern to believe that Brazil will some day be inhabited by an anthropological type. Only those who erroneously confuse race and people desire that utopian unity for this country (Roquette Pinto, 1933: 171).

In his view, the problems that were attributed to miscegenation, such as few offspring, susceptibility to disease, a short lifespan, etc., were the result of social selection. The mixing of white and black, like any other mixture, does not cause biological inferiority, but it does result in social problems. Mixed families, with white and black parents, are small, but not due to problems of infertility. Their grandparents had been exposed to the most atrocious social conditions. Although there is selection of the fittest, *mestizos* are still vulnerable to countless diseases (syphilis, malaria, worms, etc.) more than to addictions (drunkenness). *Mestizos* were not constitutionally weak, but they suffered above all from the precarious social conditions to which they were constantly subject. Anthropology proved that people in Brazil needed to be *educated,* not *replaced*. That was one of the conclusions of the First Congress of Eugenics. It should be emphasized that Roquette Pinto's anti-racialism expressed his political position. As demonstrated below, the backwardness of certain communities –the Blacks and also the Indians– was due to the poor social conditions to which they were subject.

Within this same realm of ideas, the sanitarist Belisario Penna claims that it was not race that incapacitated backlanders and *caboclos*[7], but rather epidemic and endemic diseases. Sanitation was eugenics for him. The eugenization of the Brazilian people was not a matter of race, but of hygiene (Stepan, 2005: 172).

Roquette Pinto's book, *Ensaios de Antropologia Brasiliana* (*Essays in Brazilian Anthropology*), in which he disseminated these ideas, was published in 1933, the same year in which Tarsila do Amaral painted *Operários* (*The Workers*). The painting was part of a phase in the artist's life when she was a member of the Brazilian Communist Party. By portraying all the races in the country, the painting seems to satirize Galton's representations of eugenics.

APROPRIATION OF PSYCHOLOGICAL TESTING IN THE SPANISH PEDAGOGICAL CONTEXT

Annette MÜLBERGER

annette.mulberger@uab.cat

Abstract

The paper starts reflecting on the specific problems of history of science when dealing with what is called "the periphery". The author calls for a historical account grounded on a specific local context. To do this it is necessary to start with the use of open and context-sensitive questions that could guide us in order to know why some scientific debates and practices made sense in a certain scientific community or local context, and not others. Thus, the aim of the present paper is to explore the specific functionality psychological testing acquired as scientific practice within the Spanish school system and local pedagogic tradition.
The primary sources studied make us think that the introduction and use of intelligence testing was not so much dictated by a real problem that school teachers detected in their classrooms, but viewed as a medium to legitimize professional pedagogic training. It was used to foster and upgrade the professionalization of Spanish reform pedagogy as scientific undertaking.

Introduction: historiography at the periphery

Mental testing, and specially the measurement of intelligence, has become crucial in defining the role of the psychologist in modern society. Some historical work has already dealt with how this device appeared (Carson, 2007; Fancher, 1985; Gould, 1981; Richarson & Johanningmeier, 1998; Rose, 1979; Sokal, 1990; Wolf, 1969; etc.). These works present a more or less contextualized history on how the ideas about intelligence in relation to the design of new methods of psychological measurement like the intelligence test of Binet and Simon were developed in France and transferred to the United States. Historians like Carson (2007) and Richarson & Johanningmeier (1998) explain the emergence of the mental test in France at the beginnings of the twentieth century and its spreading in North America a decade later arguing that the mental test as technical device emerges within a modern republican society characterized by a certain meritocratic tendency or organization.

But what happened in other places? How was psychological testing introduced in places like Madrid or Barcelona? In the present paper I follow the sensitivity expressed already by Morrell (1985) and, afterwards by other historians of science (see for example Gavroglu et al., 2008; and Nieto, 2008), towards a local history in which the individual and idiosyncratic actions of agents and their choices from the options available to them are as much the stuff of historical change as broader movements. Recently it has been the aim of the STEP group (Science and Technology in the European Periphery) to promote the peripheral factor as historical phenomenon. To express a transfer of ideas and practices they proposed the concept of "appropriation" in order to avoid the idea of passive reception. Now the emphasis lies in a process that confers an active role to the historical scientist on the periphery. Historical actors select, censure and promote certain scientific knowledge and practices, thereby negotiating and using certain strategies of legitimization in consonance with the idiosyncrasy of their local setting. Certain situations and local traditions allow some ways of doing and reflecting things, while simultaneously excluding or inhibiting others.

Following the direction marked by recent history of science I would like to argue for taking even a step further, revising carefully our research questions. Instead of building on questions borrowed from international mainstream historiography, it is necessary to use context-sensitive questions which may help us understand what particular contextual conditions governed and made sense of some scientific debates and practices, and not others. Thus, instead of guiding our inquiry by the assumption, for example, that intelligence testing should have been as important for Spanish pedagogy, as it was in the U.S. during the same period, we first try to understand the specific prevailing local conditions, asking whether psychological testing made sense within the context of the Spanish school system and pedagogic tradition.

Historical research is still rare on how novel (foreign) psychological techniques, like mental testing, were applied at the periphery, specifically in Spanish schools, and on the subsequent exploitation of the results obtained in such testing. On yet another level we need to know how Spanish scholars analyzed, used, and worked with some of the innovative diagnostic devices. The interesting question is not when Spanish scholars started employing modern techniques or who where the first to use these instruments. More fascinating is the question of why certain pedagogues became interested in mental testing and the problem of abnormality in Spain in general. These issues disclose interesting shifts in the role of psychological techniques taking place during the process of their appropriation in the Spanish pedagogical context.

Child abnormality: importing a new human classification

Once schooling became widespread, the “abnormal child” suddenly appeared as a socially threatening entity in the primary classroom. It was a kind of problematic child that supposedly disturbed normal education in public schools, once general schooling had become compulsory for all children from 6 to 9 years and free of charge for the poor. Although this is what many historians explain, when we examine the pedagogical texts published in Spain after the turn of the century, we find that the concept was clearly imported from the North (Del Cura, 2004; Herraiz, 1995; Huertas, 1998 deal with how the interest in abnormal children appeared in Spain).

The meaning of the term "abnormality" was very diffuse, usually defined referring to *“…the ones whose common characteristic is the incapacity, due to their physical and intellectual constitution, to follow normal pedagogical instruction as taught in public schools”* (Cuello, 1909, p. 330). Child mental abnormality became a major issue in Europe between about 1880 and 1910, carving out four basic concerns: speculation about possible causes, methods for diagnosis, and the need for special treatment and education. In Spain the most active promoter of the abnormality problematic in relation to education was Francisco Pereira (Doménch & Corbella, 1997).

Someone who linked his reflections on abnormality to criminology was a professor for law at the University of Barcelona: Eugenio Cuello Calón. He had previously received a grant by the JAE (Junta de Ampliación de Estudios e Investigaciones Científicas) to visit France, Belgium, and Germany from 1908 to 1909. Through his stays abroad he wanted to learn about experimental proceedings in the psychological study of the abnormal child and the problems related to criminal infancy. Once back from his journey, he presented a well-informed report (Cuello, 1909), commenting on recent research in that field (see also Cerezo, 2001). In terms of useful methods for diagnosing mental abnormality in children, Cuello mentioned several objective procedures such as anthropometric measurement, the observation of behaviour, questionnaires, and mental tests. He drew special attention to new mental tests developed in France (Binet & Simon, 1905; 1908). Although he valued quantitative (psychometric) methods because they *“represent a nice medium for analysis and comparison”*, he also advised that they should never be the aim in itself: *“we do not measure just to measure”*, but to determine quantitatively a phenomenon in order to assess its variations and the conditions of its existence (Cuello, 1909, p. 336). In conclusion he insisted on the utility of this research for *“it should not be forgotten that the research of normal and abnormal child psychology has not been developed exclusively to satisfy scientific curiosity but to obtain serious and precise data on which to base education”* (Cuello, 1909, p. 338).

The "abnormal” or “retarded” child became a modern classification for human beings, introduced by Demoor, Decroly, Ley (1904), and others in the framework of a more personalized child-centred pedagogy. As a product of medical classification, thought of as a specific type of human being that was not completely pathologized, a kind of child seemed destined to “exist at the margin” between pedagogy and medicine. Nevertheless, it was a precious “good” courted from several sides, by pedagogues, clinicians, psychologists, and criminologists in an attempt to establish or expand professional expertise.

Cuello’s report shows that besides his legal training he was also well-informed about recent psychological, pedagogical and clinical contributions to child psychology. He returned form his scientific travels with new ideas and techniques, extensive bibliographic references and personal testimonies from visits to various scientific institutions. Moreover, Cuello’s text indicates that it was not the actual abnormal child sitting in the classroom of Spanish primary schools that was causing problems and pressing pedagogues to find a solution. At that time the Spanish school system struggled with other big problems: there were simply not enough public schools and the existing ones were mostly in deplorable shape (see Cuesta, 1994). The problem of abnormality in school interested mainly a minority, the elite circle of the Madrid and Barcelona liberal bourgeoisie. It made sense in the context of a new child-centred pedagogy like the reform project pursued by the Free Institution of Education (Institución Libre de Enseñanza), and other European pedagogic institutions, which called for more individual treatment and education adapted to the special needs and personal traits of each child.

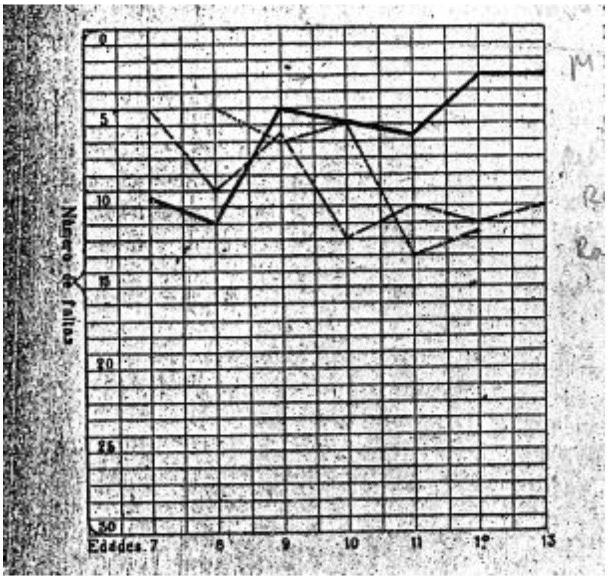
While Galton's passion for quantification bloomed elsewhere in psychology, Cuello indicated in his report that the development of quantitative methods was not on the agenda of Spanish scholars. Instead, the prime goal of progressive scholars, linked to or influenced by the ILE, was educational reform. Thus, psychological methods like mental tests interested Cuello and his colleagues only inasmuch as they were instrumental to their effort to modernize their own educational system.

Mental testing for teacher's promotion

Anastasio Anselmo González Fernández (1870-?), a teacher for experimental and special pedagogy at the teachers' college (Escuela Superior de Magisterio) in Madrid, was eager to diagnose quantitative levels of psychological capacities in children (Domenech & Corbella, 1997).

Already in 1911 González had recommended a massive application of French mental testing in official educational regulations as a procedure for the justification of teacher promotions. If we are to promote certain teachers, he reasoned, that promotion should not be subjective but based on an objective, semi-mechanical procedure. The solution is provided by Binet and Simon in their book on abnormal children (Binet & Simon, 1907): *"The method is simple, the examination [..] does not require more time than an ordinary one; while all subjective elements disappear almost entirely"* (González, 1911, p. 782). González assured that the result would be useful: *"the average of instruction would be obtained for each case, the result of the students of a series of analogue schools; based on this average it would be extremely simple to determine a numbered order in which the corresponding teachers merit ascent"* (González, 1911, p. 782).

The article indicates that he, as a trainer of teachers, instructed his students to apply tests in Spanish schools. The graph below shows the outcome of one such research, studying attention levels of schoolchildren at different schools.



Two student-teachers measured the level of attention in three different kinds of schools in Madrid: a public school, a traditional private school, and what was called a "radical" private school. No names are given but it is highly probable that the traditional private school was a Catholic school run by a religious congregation, while the radical school was probably a "freethinker" school run by anarchists or masons.

The scale on the left goes from 0 errors (top) to 30 errors (bottom), while age increases from 7 (left) to 13 (right). González proudly exclaimed: *"It can be seen that the best results have been obtained by the public school"* (González, 1914, p. 784). Although the children start with a lower attention level in public school, at the age of 7 they quickly surpass the children from other schools showing the lowest number of errors from 9 years onwards (see darker line going upwards).

We find, then, that initially Anselmo González and his trainees did not use psychological testing arrangements to detect abnormal children. He proposed an allegedly objective technique for organizing and prescribing a new merit system for teacher promotion. In this case the introduction of scientific psychological measurements was taken for an objective, apolitical way of comparing different kinds of schools. In his doctoral thesis González had already stressed that one of the greatest influences on the attention span of pupils is the pedagogical method used by the teacher. Therefore he was arguing for higher scores and consequently the faster rise of the public school teacher, while downgrading the pedagogical methods used at private schools (allegedly unable to maintain a higher attention level in pupils).

González's publication shows how pedagogy became a battlefield for the growing social and political dissonance in Spanish society during the *Restoration* period, before World War I. In an attempt to organize adequate education, several social groups had founded their own schools which were competing with each other. In this setting his text testifies his demand for a just distribution of the salary, which seemed to be more pressing than selecting abnormal children.

Mass testing in Spanish schools

A few years later,[1] González worked out a book on mental testing entitled *Diagnosis of Abnormal Children* (González,1914) (see also Cerezo, 2001 and Doménech & Corbella, 1997, some of the few historians that deal with Gonzalez's pedagogical contribution). In the well-informed book he discussed different modern intelligence testing systems.

After describing the various proposals and despite problematic aspects pointed out by Treves, Safioti, and Nayrac at the first International Conference of Paidology in Brussels, he proceeded to advocate Binet & Simon's pedagogical and psychological tests. Referring to the version of 1911 he stated: *"Binet's method satisfies all the exigencies of a good pedagogical diagnostic method, and with the help of it we can obtain a classification of the pupils that allows to send every child to the institution which corresponds to its intellectual level"* (González, 1914, p. 221). The book informs of massive application of the test at Madrid schools, done by his teaching students: *"From the moment Binet's definitive test was published, all the students of the course on abnormal pedagogy at the teacher's college applied it in various schools in Madrid. This has allowed us to obtain a high number of observations because usually each student has studied 200 schoolchildren, which nowadays makes a total sum of more than 20 000 observations"* (González, 1914, p. 212).

While applying the test, Spanish pedagogues like Gonzalez introduced several changes to the tasks included in the Binet-Simon test and its application. One of the first adaptations was to alter task order, exchanging exercises for eight year olds with those for nine year olds. They justify this change by referring to an observation also made by their French colleagues, namely, that a crisis in development takes place at that age, making the correct selection of tasks extremely difficult. Another significant modification was to increase the time limit for tasks.

Nevertheless, acting at the periphery, González was eager to reduce the relevance of these modifications while insisting that *"the basis of the Binet-Simon method subsists, because our modifications affect only details, directed towards a better adaptation of the method to application in our country"* (González, 1914, p. 219). He concluded proudly that the results are completely compatible with those obtained by foreign researchers: *"Thus, there is no disagreement; on the contrary, the results are identical and this amounts to new precision checking of the method for the assessment of child intelligence"* (González, 1914, p. 216).

Conceptual and technical appropriation at the periphery

With the rise of industrialization and the spread of democratic ideas during the nineteenth century life also changed in Spain, at least in some regions and in the cities. While the state was acquiring more responsibility, the topic of education became an issue of debate. From the 1880s on, efforts had been made to establish alternative private schools. One initiative was that of the ILE, promoted by some of the liberal and republican intellectuals. Another was pushed forward by anarchist workers associations. Towards the twentieth century most of the supporters of these initiatives realized that an educational reform of the country could not be based on the founding of private alternative institutions but needed a broader initiative led by the state, organizing public education for all. But the continual blocking of school reform initiatives by some conservative politicians and authorities who feared an emancipation of the "mob", slowed this tendency (Cuesta, 1994).

Still, at the beginning of the twentieth century we find Spanish public schools in a deplorable condition. The overcrowding and unhygienic situation let infectious diseases spread easily; education itself consisted mainly of exercising severe discipline (García Hoz, 1980). These circumstances prompted Spanish physicians to initiate hygiene campaigns while pedagogues fought predominantly for bearable working conditions.[2]

[1] following historians like Domenech and Corbella (1997) it was in 1914 edited again in 1929.

[2] Of course the situation was much better in private schools, especially in the case of recruiting the offspring of the better situated social classes. Secondary education was mainly offered in private elite schools which usually were in the hands of different religious congregations (Jesuits, Franciscans, Benedictines, Capuchins, Aesculapius, etc.).

In this context, scholars started a campaign to detect and separate "abnormal children" from others for reasons similar to those of the hygienic movement: to *purge* the classroom of the infectious and unhealthy *germ* called "abnormality" in an effort to prevent things from becoming socially dangerous. Cuello, for example, said that the abnormal child was not only disturbing at school but also a problem at home because of the *"ease with which they infect other family members with mental abnormality"* (Cuello, 1909, p. 376).

Nevertheless, for half a century Spanish institutions were not prepared to deal with the individuals thus sorted. Molina's research (Molina, 2009) shows that the "Central School for Abnormal Children", founded 1922 in Madrid, was one of the very few public specialized institutions. This implies that using mental testing to separate normal from abnormal children did not make much sense during the first two decades of the twentieth century in Spain. Private Schools were already economically selective and in public and rural schools grouping in the classroom was normally the only option anyway.

The primary sources studied here of Anselmo González make us think that the introduction and use of intelligence testing was not so much dictated by a real problem that school teachers detected in their classrooms, but viewed as a medium to legitimize professional pedagogic training. It was used to foster and upgrade the professionalization of Spanish reform pedagogy as a new scientific community. Accordingly, to enhance psychological expertise in his pedagogical students, González published a textbook in 1921 specifically on psychological testing.

In Madrid, Barcelona, and other big cities, competition was rigorous among private and public schools. The new professional community coming from training in teachers colleges faced competitors. Therefore teachers like González at the public school used the testing method to mark themselves as more professional, scientific, and modern –top quality pedagogues. As part of this effort to distinguish and promote public instruction we find a surprising shift of functionality in the appropriation of the mental testing technique. Anselmo González proposed in 1911 to use Binet and Simon's mental tests as an innovative, rational, allegedly objective and apolitical instrument for officially regulating advancement in teaching careers. Within the Spanish educational context it seemed more pressing for a public teacher to fight for a decent salary by proving the superiority of his pedagogy over that of his competitors from various private schools, than to worry about classifying individual children in terms of normality or abnormality. With his awkward graph in hand, González tried to demonstrate the superiority of pedagogical methods employed in public schools by revealing results of attention level measurement.

With regard to the process of appropriation, the texts of the Spanish authors expressed timid critique and modified the material only slightly, while expressing great respect for the foreign publications. Being in the position to apply a translated version of the French test in Spanish schools let them feel nearer to the researchers they idealized, like Decroly, Binet, and Claparède. By attending international meetings, undertaking scientific travels welcoming visits of foreign researchers, and taking advantage of the access they had to certain scientific literature and instruments, the Spanish pedagogues sought contact with modern science (see also Mülberger, 2008). Paper and pencil tests like Binet and Simon's intelligence test made it possible for Spanish teachers and pedagogues to act as scientists without needing well-equipped laboratories and sophisticated technical know-how. The testing seen as a scientific endeavour easily crossed national and scientific borders. Gonzalez argued complacently that the test had been applied successfully not only in America, England, and Belgium, but in Spain, too. Nevertheless, it was not scientific curiosity that prompted scholars like him to appropriate the test to his local context, but a desire within the Spanish reform movement to legitimize teacher training programs and to upgrade and make more professional the pedagogic occupation.

Abstract

The present paper deals with the intelligence testing applied and promoted by a Catalan teacher called Llorenç Cabós in the 1920s. This teacher of a graded school of Barcelona decided to learn by doing, organizing a series of paper and pencil testings in the classroom. Our research evidences the supportive policy of the local government for such an initiative and how a local daily newspaper referred to the event as a kind of scientific spectacle.

The thesis we defend is that there was no need in Catalan schools to classify students but a clear interest to professionalize teacher's career and to promote certain schools. Testing meant to Cabós to run an experiment. Tests were easy to get and to be used to obtain numeric results. Whatever these numbers meant, Cabós interpreted them as a direct contribution to science.

Introduction

In Spain some pedagogic reform initiatives appeared in several places, especially in the areas in and around the cities of Madrid and Barcelona. As we will see, in Catalonia the specific local and political context left space and even empowered new proposals in the field of pedagogy with a clear interest in psychological issues (see also Cerezo, 2001 and Moreu, 2000). This tendency became more evident in the 1920s, a decade in which new topics like "intelligence" were raised. Our main interest lies in knowing how psychological testing methods were perceived, used and spread in the local Catalan context. Therefore, the paper will focus on the initiative of using psychological measurement in pedagogy pursued in the 1920s by the pedagogue Llorenç Cabós.

We will approach our topic by tracing, in the first place, the political and social context. The twentieth century started in Catalonia displaying strong social conflicts. The first general strike organized in 1902 in Barcelona is a good example for the workers growing reaction towards the new capitalist power of Catalan industry. The tragic week in 1909 and the crisis of

1917 evidenced an extended discomfort, certain instability of the middle classes, and growing strength of the workers movement.

In such a setting, marked by social changes and tensions, we find several groups that viewed school as a medium to enhance their political interests and social values (Cuesta, 1994). One group can be characterized as the conservative, Madrid-oriented Catholic sector, enhancing traditional schooling organized by religious congregations. A second group was the liberal and republican bourgeoisie looking for an inter-confessional school system. These reforms were often strongly influenced by and connected to the *Institución Libre de Enseñanza* of Madrid. In their attempt to reform the educational system they took over the spirit of modern pedagogy based on the child's needs. Some of them defended the right of the child to receive education in their mother tongue, which meant the introduction of Catalan as official school language. A third group of schools underlined the necessity of laic instruction to ensure confessional liberty. Also from the anarchist workers similar initiatives for a school reform were launched, exemplified by Ferrer's "Escola Nova" (Cuesta, 1994).

In this paper we will focus on an impulse for mental testing that came from a Catalan teacher called Llorenç Cabós i Badia, linked to the third, rationalist, group of Ferrer i Guardia. The former worked in one of the public graded schools in Barcelona. The reason why we deal with his work here is twofold: first, he became one of the main popularizers of psychological testing in Barcelona and, second, he was the first to adapt intelligence tests to the Catalan linguistic context.

He was no lonely forerunner but one of the historical actors within a social and institutional network that opened space and even enforced projects dealing with the introduction of psychological testing in the classroom of Catalan schools. At a time of renaissance of Catalan industry and culture, the regional Government (Mancomunitat) was actively trying to improve primary education. In this regard the policy and political intervention developed around 1920 by the regional government and the Barcelona city hall was clearly supportive.

A pedagogue introduces himself into the world of testing

In the Catalan newspaper *La Vanguardia* of the 19th of March 1922 as well as in the pedagogical journal in Madrid "*Revista de Pedagogía*" (1922, I, 4, p. 160) we find an anonymous note informing about the visit of teacher-students to Cabós' school to see a trail in infantile intellectual measurement applied to one case. It was a "public demonstration" only for a group of students trained to become teachers. The newspaper commented that the mental testing presentation was made with great exhibit of skills ("*con gran maestría*") by Cabós, using the Binet-Simon test. The newspaper *La Vanguardia* wrote that in the end "*the visitors remained extremely satisfied with such a practical lesson*" (LV, 19th of March 1922; p. 11).

Cabós was a teacher at a graded school located at the "Paseo San Juan" (nº 43) in Barcelona, interested in psychological testing methods. In 1920 he published the results of a seemingly auto-didactical application of the Yerkes, Bridges and Hardwick test to 100 schoolboys (with ages between 7 and 14 years) (Cabós, 1920). The American scale was a modified version of the Binet-Simon edited in 1915 under the title *"A point scale for measuring mental ability"* by Warwick & York (Baltimore). At that time, several psychological testing systems were sold on the Spanish market[1]. Cabós informed that he had other scales available but that he started applying this one for no other reason that for "having it at hand".

In his report it is clear that the local authorities supported him on this behalf. He thanked the school director and the Cultural Committee of the Barcelona city hall (Comissió de Cultura de l'*Ajuntament de Barcelona*). This Committee, created in 1917 under the direction of Manuel Ainaud i Sànchez, was efficient in ameliorating the public school service in the city by carrying out an ambitious plan that included the establishment of several new well-equipped public schools (called "Grups Escolars"). The report published by this committee in 1916 shows clearly the intention of the city hall to support paidology, understood as modern science of the child. Already in 1911 Eugeni d'Ors, a member of the committee, had recommended Catalan teachers to apply this new technique in order to register and classify retarded schoolchildren. Now that Cabós was willing to work on a trail run, the Committee supplied the school with a substitute teacher for the course 1920-21 permitting Cabós to dedicate his time to the testing. The policy of the city hall of that time clearly enforced paidology as research project and training program for teachers and enhanced local applications and adaptations of intelligence tests.

Before exposing the results in detail Cabós announced his positive impression that "*The Barcelonean child is calculating, ingenious, lively and* mischievous", he stated satisfied (Cabós, 1920, p. 41). After examining 100 children of different ages he could show with the help of tables and graphs, the intellectual superiority of the local infantile population. Here we reproduce one of the tables where he compares his scores with the lower scores obtained by Yerkes-Bridges (Cabós, 1920, p. 44):

---

[1] The Yerkes et al. scale cost 2 dollars at that time; for a list of different tests (see Herraiz, 1995).

In 33% of the children he diagnosed a slight backwardness, while 62 % were advanced with regard to their age. Only in 5% of the cases the mental age was the same than the chronological age. These results are surprising because previous attempts to apply intelligence tests had evidenced a lower performance of Spanish children (Comissió d'Instrucció Pública i Belles Arts, 1916).

Cabós' contribution (1920) ended with three conclusive statements. First, he could inform that the application of the metric scale of intelligence is really easy. This statement surely invited other teachers to follow his example. Secondly, in his opinion the application of psychological tests should be made compulsory for graduate schools, where there is enough personnel to take care of this service and therefore not to be applied in unitary schools. This meant that only certain privileged, bigger schools should or could organize massive psychological testing. Although the school service of the city was still deficient in the 1920s Barcelona was proud of some modern (private) "model" schools like the "Escola del Mar" or the "Escola Horaciana". Thirdly, Cabós insisted in the importance of keeping a register of the achieved results for each student.

Expressions like the following: *"acts say more than words"* (Cabós, 1920, p. 44) show his preference for quantitative information and the value he gives to numbers *per se*. This becomes evident in his report where he dedicated more space to expose numeral results than to interpret them. In his opinion: *"the view of these numbers invites the reader to numerous thoughts which should be made by himself"* (Cabós, 1920, p. 43).

The attraction of testing: popularizing psychological testing with the help of public demonstrations

Noticing general interest in his testing and his success of his public demonstration, Cabós promised to complete the demonstration very soon. This time he would apply the Terman test (1916), a popular intelligence test which was a revised version of Binet-Simon's. The most important difference was "mental age" being replaced by "intelligence quotient".

About five weeks later, news on Cabós performances with testing appeared again in the newspaper. Now it was Cabós who went to the teacher's school ("Escuela Normal de Maestros") to give a public demonstration of the use of the Terman test. He applied it to measure the intelligence of a 15 years-old boy. With regard to the tasks included in the test the newspaper comments: "*These vary in number and in difficulty, depending on the age (...). They are accurate and demanding, some did call the attention because of their ingenuity*". All in all, it was clear that "*The experiment resulted* (to be) *very interesting...*" (see Notas in *La Vanguardia*, 2nd of May 1922; p. 5).

In a second publication in the "Journal of Pedagogy", Cabós (1922) analyzed more carefully the performance of his children in each task. Therefore he recognized the linguistic problems of his sample. The task of constructing a sentence using three given words, for example, resulted very difficult, being solved only by 37 % of the schoolboys. The explanation of this result comes right away: "*The language tasks are more difficult for bilingual persons*" (Cabós, 1922, p. 94). The majority of his school children were Catalan or Valencian. They spoke two languages: their mother language and Spanish.

Mental testing was something new to the Catalan public, although there were some schools proud of working with personal "anthropometric profiles", introduced in selected schools like the graded primary schools "Districte VI", directed by the physician Estrany. This school counted with a complete medical support permitting a technical control of the schoolchildren with regard to physical, psychological, and pedagogical variables (Galí, 1979). Another similar school that could count with medical and psychological support was the "Escola Horaciana". Galí informs of a regular psychological control that was carried out in these private schools to know the intellectual age of each child.

It is important to keep in mind that Cabós did not have any formal training as scientific researcher in psychology or in psychological measurement. His audacious decision to "learn by doing" turned him into an attractive example or forerunner, a courted expert during a time in which curiosity and interest for this new scientific way of doing paidology was growing in the local setting. For this reason he received invitations, such as to give a course at the Barcelonan Teacher Association on *"the measurement of intelligence*" (see Notas in *La Vanguardia*, 8th of July 1923, p. 5) and lectures at the Teacher's summer school. The way in which he introduced the intelligence measurement in the first course for teachers shows that for him the application of a mental test meant to run a psychological experiment. Testing was perceived as a way to introduce scientific methods into the field of pedagogy. In order to know what he presented in the second course it is worthwhile to take a closer look at the report of the summer school.

The teacher's summer school: a place to spread mental testing

After his start into psychological testing, Cabós was pushed further into intelligence measurement by the *Federation of Catalan National Teachers* (*Federació de Mestres Nacionals de Catalunya*), which was the entity that asked him to lecture on this subject in the Summer School for teachers of 1922 held in Barcelona (Cabós, 1923; Monés, 1977).

This Federation unified several local teachers associations that had emerged after 1901. Previous to the creation of a teacher's trade union, it tried to supply support to public teachers and cooperated between 1914 and 1923 with the pedagogical reform initiatives launched by the city hall and the regional government (Monés, 1977). One of these initiatives was the Summer School for teachers (Escola d'Estiu) held during this period as an intensive course of one month of duration during school vacations to foster pedagogical training for professionals in the field of education. The school offered an interesting forum for a debate about recent pedagogical tendencies and methods. No wonder topics like abnormality, intelligence, and psychological diagnostic methods were dealt. Surely Claparède's personal visit and participation as invited lecturer in the summer school of 1920 helped to enforce interest in these topics.

Using foreign intelligence tests, Cabós recognized the need to adapt the language test to the Catalan speaking population. In a talk he gave at that teacher's summer school (Cabós, 1923) he informed about an adaptation he had made of the Terman vocabulary test. This test consisted in asking the child to define words like friendship, laughing, and cinnamon counting the number of correct definitions.

Instead of preparing a list of the most common words used by his local population he preferred to translate the list of A.M. Aguayo's collection of Spanish words assembled in Cuba (see Aguayo, 1921) into Catalan. Thus, Cabós explained: *"Taking into account the need of work in Catalan, we have limited ourselves to translate, as exactly as possible, the Spanish Vocabulary of Dr. Aguayo, evidently as a provisional measure, willing to modify it due to the demand of the practical application which will hopefully get extended all over Catalonia"* (Cabós, 1923, p. 55).

Cabós not only adapted the test itself to the local language, he also prepared a booklet for the application of the Terman scale (Quadern-registre) in Catalan language. The text was edited by the Committee for education of the city hall and distributed for free at the teacher's summer school. The handing out of this material together with his explanations on the different tasks of the test was a clear invitation for Catalan teachers to apply intelligence tests in their respective classrooms. He ended his talk insisting in the necessity for the modern teacher to have at hand an "*accurate research instrument*" (Cabós, 1923, p. 59).

Here we reproduce the first two pages of Cabós' record-booklet for the Terman scale[2].

Aqueixos tests han estat seleccionats havent tingut present sa adequació, varietat i rapidesa amb que poden ésser posats. Si hom posa solament els tests de l'escala abreujada tindrà cura de donar-los-hi la valor següent: De l'any III al X, 3 mesos per cada test vençut; a l'any XII, 4 mesos per test; a l'any XIV, 6 mesos; a l'adult mig, 7 1/2 mesos; a l'adult superior, 9 mesos.

Conclusions

In the Catalan pedagogical context we find in the 1920s a noticeable sensibility with regard to psychological testing. In an attempt to modernize pedagogy with the use of scientific methods and experimentation, local authorities stimulated non experts like the pedagogue Llorenç Cabós to start applying the new accessible devices of mental testing. In Spain some public entities and institutions already cited in our paper like the city hall and the regional government was clearly supportive.

In the international scientific exchange, mental tests were a very attractive product for two reasons: First, they were cheaper than any of the previous requisites for psychological experimentation based on physiological brass-instruments. Second, also their use was perceived as more intuitive and easy. The results obtained in form of number seemed to stand for themselves as scientific valuable and comparable data. Thus, the project of a modern science as universal undertaking publishing and commercializing affordable technical methods helped Catalan pedagogues to get in contact with modern scientific pedagogy and paidology.

A teacher like Cabós, with no previous psychological training, was able to translate from French or English the tasks or questions to be passed to the school-children and, of course obtained results. Whatever these numbers really meant or represented, it was a way to compare, what he considered scientific results with what other (foreign) researchers had obtained. The act of passing the test became a kind of spectacle that was even mentioned in the daily Barcelona press like the newspaper *La Vanguardia*.

The local city hall made possible the distribution for free of a booklet with instructions, tasks and the register of results translated into Catalan by Cabós. His public demonstrations, his lectures at the summer school and other teacher's meetings, his publications in several pedagogical journals like the Butlletí (also distributed for free to the Catalan teachers, sponsored by the regional government), helped to spread mental testing in Catalan schools.

In our view psychological testing did not start as a result of a local need to classify children by their mental age or IQ in public schools of Barcelona. It seems to have been a way to professionalize the work of the teacher, to turn the teacher into a scientific researcher (see Mülberger's paper in this session). The competition between schools enforced a comparison. Therefore Cabós refers proudly to his modern, graded school and the intelligent Catalan children present in its classrooms. He was eager to show the intellectual superiority of his sample. In the case of the linguistic task in which his children did not perform that well, he excused them, mentioning their bilingualism. At this moment he recognized the need to translate the language task into Catalan. Whereas the pedagogical laboratory under the direction of Dwelshauvers would soon undertake a sampling of the most used Catalan words, Cabós at that time had no other repertoire at hand than a word list elaborated in La Habana.

WHEN AN INSTRUMENT CROSSES BORDERS: MEASURING MIND IN EARLY TWENTIETH-CENTURY FRANCE AND AMERICA[1]

John CARSON
University of Michigan, USA
jcarson@umich.edu

Abstract

How have modern democracies squared their commitment to equality with the fear that disparities in talent and intelligence might be natural, persistent, and consequential? This talk explores the story of how the American and French republics turned to the sciences of human nature, and specifically particular practices of measurement, to help make sense of the meaning of human inequality. These sciences' exploration of the status and character of human mental differences, it contends, provided a range of political theorists, social scientists, and practical politicians with seemingly objective grounds for interrogating the limits of human equality and developing what could be represented as a justifiable basis for social distinctions. In general, mental philosophers and political theorists on both sides of the Atlantic argued that if the "false" distinctions of wealth or family background or beauty or any of the other accidents of birth could be eliminated, then the "true" ones, those reflecting fundamental aspects of a person's nature, could come to the fore. However, over the course of the nineteenth and twentieth centuries, the specific ways in which each society responded to the evolving sciences of human nature diverged sharply as these nations addressed the problem of balancing equality and difference. This talk will investigate the nature of that divergence and the crucial role that determinations of, and contestations over, ways of assessing intelligence played in both societies, constituting shadow languages of inequality used to help organize educational systems, justify racial hierarchies, classify army recruits, and direct individuals onto particular educational and career paths. It will also explore some of the hesitations about, and resistances to, these practices as they were elaborated and enacted.

"Standardizing the mind is as futile as standardizing electricity," Justice John W. Goff of the New York State Supreme Court proclaimed in 1916, thereby proving himself as prescient about psychology as he was about physics.[2] Electricity, as the folks at Duracell or Eveready could attest, has become a very well standardized object. Indeed, as Simon Schaffer has

[1] This talk is adapted from John Carson, *The Measure of Merit: Talents, Intelligence, and Inequality in the French and American Republics*, 1750-1940 (Princeton: Princeton University Press, 2007).

[2] "No Psychology in Law," *Literary Digest* 53(1916): 405-406 and "Court Bars Binet Test," *The New York Times*, July 19, 1916, p. 7.

argued, one of the great achievements of late nineteenth-century electro-physics was its creation of a "manufactory of ohms," a site where a standardized electrical unit could be produced and converted into a black-boxed instrument capable of being dispatched around the world to regulate electrical practice and the electrical measurements on which it depended.[3] Schaffer's story of the ohm does not stand alone. Work during the last two to three decades on the history of metrology (the science of standards and measures) has again and again found the Schaffer's basic narrative applies, whether to the standardization of the meter as described by Ken Alder or of the lab rat, as recounted by Karen Rader.[4] Various possible standards are proposed, often by rival research groups; technical problems in constructing and making reliable the standard are eventually solved; and the standard that triumphs is then both distributed across a network of relevant practitioners and used to regulate subsequent work in the field. Bruno Latour has in many ways embraced this understanding of standardization as one of his central analytics, describing the development of actor networks with centers of calculation that regulate far-flung practices and ensure that there is calibration throughout the system.[5] It is essentially an imperial story, where a metropolitan institution defines (and often physically maintains) the standard, and then demands that provincials everywhere adopt that standard if their work is to be taken seriously.

This picture constitutes, I think, one of the main meta-narratives that historians of science and other science studies scholars have at our disposal for understanding the development and deployment of scientific instruments and standards. But it is not the only one. A second narrative, drawn one might say more from post-colonial studies, emphasizes less the co-optation of the periphery by the center, and more the adoption, adaptation, and repurposing of artifacts and ideas as they circulate between putative metropoles and provinces.[6] Two very well known examples in science studies of this sort of story are Madeleine Akrich's research on the transfer of technical objects, as she calls them, between Europe and Africa, and Ron Kline and Trevor Pinch's study of the role of the user in shaping the early history of the automobile in rural America.[7] Both emphasize that the wishes and designs of producers, including their imagined consumers and the imagined uses of the artifacts, are only one of the factors shaping what will happen when a technical object is moved to a new locale. Instead, the nature of local conditions, the cultural contexts into which the artifacts are introduced, and the needs/interests of those wanting to adopt the artifacts all have powerful influences on what will be adopted and how it will be used. Rather than the center dictating to the periphery and regulating its actions, this narrative emphasizes the plasticity of techno-scientific objects and the power of local conditions and actors to remake, either subtly or dramatically, the object being transferred as it is adapted to its local environment. It is a story less of empire than of evolution, with emphasis on variation and local adaptations.

This second meta-narrative also resonates with the early history of the Binet-Simon metric scale of intelligence. Created in France by Alfred Binet and Théodore Simon in the period 1904-1911, the Binet-Simon scale quickly spread widely, not only to the United States, but, as the papers in this panel demonstrate so well, to many parts of the world. Importing the Binet-Simon, however, almost always required some sort of local adaptation, if only translating it into the relevant language. And most often many other transformations were made as well. Provincials, in other words, were rarely content to take the instrument as defined in the metropole and to let its structure discipline their activities. Rather they engaged with it creatively, transforming elements to fit local needs and contexts. Such a story certainly holds true for the United States, itself a nation as much on periphery as in the center vis-á-vis Europe even up to the early twentieth century. When the Binet-Simon metric scale came to America, though many psychologists embraced it quickly, they just as quickly began to change it, adapting the instrument to not just its new language, English, but to its new home. And they did so with scant worry about what psychologists in France might think about their endeavors.

Thus, we seem to have two compelling but rather different, if not contradictory, narratives for the dissemination of the Binet-Simon metric scale in the early years of the twentieth century. If one foot lay clearly in the rather imperializing landscape of metrology, of the production of potentially universal standards supervised from metropolitan centers, the other lay just as firmly in the provincializing terrain of evolutionary adaptations and transformations in response to local conditions. In particular, these competing accounts raise two important questions: first, how did local practitioners, in the process of translating, adapting, and often transforming the metric scale, still have confidence that it worked? What convinced them of

its efficacy once it was no longer the "same" instrument as that being deployed in Paris? And second, how were results arrived at within the context of one locale meant to be linked with those in another? Was there interest in the creation of a universal measuring standard, and if not, what was the status of this instrument, and by implication, the field of mental measurement meant to be as a science? In my brief time this morning, I will try to cast at least cast a little bit of light on both of these questions by taking a much too quick look at the early history of the Binet-Simon test in France and America.

When Alfred Binet commenced work in 1904 on the first version of his metric scale, published in 1905, the direct impetus was his appointment to a ministerial commission on children lagging in school. The scale began, as Binet and his colleague Théodore Simon explained at the Fifth International Congress of Psychology in Rome (1905), as a new means of diagnosing idiocy, imbecility, and feeblemindedness (*débilité*), and distinguishing these subnormal types of intelligence from normal minds lacking sufficient training. Their initial goal was to replace what they deemed the "arbitrary" classificatory methods of doctors and educators with a procedure for defining degrees of intellectual deficit that was more objective, precise, and above all scientific. The thrust of Binet's work in the 1905 scale was to remedy this lack of precision by creating a series of tasks that would differentiate unambiguously between the normal mind and the various degrees of subnormal intelligence.[8]

To accomplish this, Binet developed a series of thirty tests arranged from simplest to most difficult. Calibrated through application to "normal" children, the series contained sets of tests that, Binet contended, could be passed by individuals of one level of intelligence, but not of a level below. At its simplest, therefore, the Binet-Simon was constructed as a series of barriers that would stratify a population into its "natural" intellectual levels along the scale of mental development. While Binet originally conceived of the test as limited to subnormals, the test's "genius," as it were, was its equation of subnormal intelligence with arrested normal intelligence and thus its creation of a scale that in principle could apply to normal children as well as the feebleminded. Adhering to a fundamental tenet of French clinical psychology, that the pathological differed only in degree from the normal, Binet imagined the metric scale as a means of determining a precise relation between abnormal states of intelligence and normal intellectual development. "Here, in our studies on children," Binet commented in 1905, "it is not only a comparison that is necessary, it is a physiological, anatomical and anthropological table of standards [barême] to which one must return every time with each new subject to determine in what measure this subject is inferior to the normal."[9]

The crucial word here is "barême," which signified a standard that captured some aspect of what it meant to be "normal" and that could be used to analyze deviations from this normal state. Binet's "barême," however, suggested a second feature as well: the possibility of measuring the degree of deviation from these objective standards. And Binet's scale itself did not just compare diseased with healthy, it also measured the degree of intellectual development. This became particularly apparent in his 1908 revision of the scale, which was comprised of an almost totally new collection of fifty-six tests, arranged in sets according to mental age, and calibrated so that most normal children of the relevant age could pass them while at most half of the age just below could do so. In addition, Binet added to the 1908 scale an explicit procedure for determining a numerical intellectual level, the "niveau mental," and more rigid criteria for a correct response. These changes substantially increased the emphasis on precision and expanded the scale's target population to include normal children as well as subnormals.[10]

As is well known, the reception of the Binet-Simon intelligence scale in France was lukewarm at best. Almost immediately, French physicians proved hostile to a diagnostic technique that apparently challenged their authority, a reaction that pushed Binet to reorient his intelligence work away from medical diagnosis and "toward practical and social questions," as he declared in 1908.[11] Although Binet worked assiduously to identify a range of possible uses for the scale and to promote it to everyone from the Ministry of Education to the French army, the actual uptake of the instrument was modest. Binet's sudden death in 1911 at the age of 54 deprived the scale of its most important champion. While most French psychologists acknowledged that the Binet-Simon was a measuring instrument of some practical value, few found it of more than limited relevance to their own research programs. The orientation of French psychological investigation in the early twentieth century was overwhelmingly toward clinical studies of individual pathology or laboratory experimentation on basic psychological functions, not toward the practical applications of psychological science to social problems. Moreover, most institutions remained content with time-honored methods for identifying the mentally subnormal (the arrièrés), the mentally superior, and those best suited for certain types of training or occupations.

Outside of France, however, the response to the Binet-Simon metric scale was anything but ambivalent, notoriously so in the case of the United States. The 1905 Binet-Simon scale arrived in America in 1908, one of the spoils of a research junket to Europe undertaken by American psychologist Henry H. Goddard of the New Jersey Training School for Feebleminded Girls and Boys in Vineland. Goddard commenced experimenting with the scale soon after his return, but found it of limited value. When Binet published the 1908 revised Binet-Simon, Goddard at first hesitated to use it, recalling later that it had "seemed impossible to grade intelligence in that way. It was too easy, too simple."[12] Intrigued by the possibility, however, Goddard finally administered the revised instrument to residents at his school, and reported himself to be amazed by the results. The scale, he declared, provided accurate diagnoses of the mental levels of all of the children he had examined. What had taken Goddard and the staff months to determine through long exposure to the subjects, the Binet-Simon was able to reveal in a single testing session.[13]

It would soon be clear that Goddard's experience was by no means unique. By 1916, when Lewis Terman completed the Stanford-Binet, his version of the Binet-Simon intelligence scale, intelligence was already something of an industry in American psychology. Articles either about the Binet-Simon scale or research data generated by the scale filled professional journals; numerous rival versions of the scale competed for clientele and professional dominance; and a great deal of hand-wringing was in evidence about the improper use of the technology by those deemed "ill-trained" to apply it appropriately. American psychologists were infatuated with the test; they adopted with few reservations what their French counterparts found either uninteresting or problematic. In the process, however, they adopted wholesale the version of intelligence—singular, hierarchical, unidimensional—built into the Binet-Simon instrument, as well as a vision of how the scale might best be deployed.

Once Goddard began the process of Americanizing the intelligence test, others quickly followed. Terman and his student Hubert G. Childs began to investigate the 1908 scale in 1910, conducting extensive experiments on schoolchildren in California that would result in their first revision of the scale, published in 1912.[14] Edmund B. Huey praised the test in 1910 as "the most practical and promising means yet made available for determining the fact and for measuring the amount of mental retardation" and produced a translation, as did Fred Kuhlmann in 1911.[15] Other psychologists also jumped into the fray. Although complaints about details of the French scales abounded and almost every psychologist altered the tests at least slightly to meet their own needs, the Binet version of the scale remained dominant. Many psychologists were uneasy about this fact, aware that a measuring instrument designed for Parisian children might be inaccurate for Americans, with their different set of culturally specific background knowledge, a criticism Leonard P. Ayres leveled explicitly in 1911.[16] In 1916 these worries were mostly alleviated with Terman's publication of the Stanford-Binet, his overhauled version of the Binet instrument standardized on an American population.[17] While some psychologists—most notably Robert M. Yerkes—continued to express misgivings about the Binet approach and to propound alternatives, the majority of the testing community adopted the Stanford-Binet as the standard test for measuring intelligence, a position it maintained until well into the century.[18]

With these quick sketches of the very different careers of the Binet-Simon metric scale in France and America in mind, I would like to return to the issues I posed at the outset. On the surface, the story of the Binet-Simon scale does not fit very well with the standard metrological narrative about the development and deployment of standards, the dominance of metropole over periphery. Although Binet and Simon's express purpose was to standardize diagnoses of subnormal intellect, and although they built their equivalent of the standard ohm—their barême based on the performance of Parisian school children—into the heart of the scale, the American adopters of the instrument never felt particularly comfortable with this standard. Many did admit that simply translating the scale was enough to make it work; indeed, recall that Goddard reported himself to be astonished by how accurately the 1908 scale was able to classify the subnormal population in his asylum. Nonetheless, almost all of the American psychologists who began using the Binet-Simon scale tinkered with it, changing

tasks, altering acceptable answers, and generally remaking the scale to fit their own conceptions of what an accurate measurement of intelligence would look like, given the population they were working with. They seemed, in other words, completely unworried about the decoupling of their instruments, and thus of their measurements, from those produced in Paris. Terman's creation of the Stanford-Binet completed this process. Not only did he replace most of the Stanford-Binet tasks with his own, but introduced a new barême as well, his 965 California school children. What was now left to connect the findings produced by the Stanford-Binet in America with those of the Binet-Simon in Paris?

The answer, of course, is not much, though it is also not clear that anyone really cared. With Binet's death there was no central figure in France with sufficient interest and authority to demand that the measurements remain commensurate, that the Parisian standard prevail. Moreover, the kinds of problems that the metric scale was meant to address were in many ways local ones: which students needed special education, which recruits would benefit from advanced training. There was little social need to have these determinations be able to travel and to accord with one another. When that issue did become pressing in the United States, it was to make the evaluations work on a national scale, and quickly the Stanford-Binet with its ability to provide a single measure, the IQ, came to fill that role. For decades after, one of the most important ways of authenticating new mental tests in America would be to ensure that they correlated with Stanford-Binet IQ scores. So perhaps it was the Stanford-Binet that eventually took on the role of standard setter, with IQ becoming a widely employed way of expressing the measured level of a person's intellect.

But with regard to the Binet-Simon, I do not want to suggest that the story of its dissemination unproblematically fits the model of adaptation and local contextualization. Certainly in the U.S. case, and I suspect in others we will hear about today as well, there were clear limits to how much the Binet-Simon could be transformed. In particular, even though its specific standard population did not end up prevailing, its method of using age stratification as a way to assess intelligence and its vision of intelligence as a singular entity that could be numerically gauged did. Almost every American psychologist who worked with the metric scale considered the technique of using age-stratified performance by "normal" children as the way to assess precisely intellectual deficit to be Binet's key innovation, and most marveled at how well that worked. They might not agree on the specific tasks that best correlated with chronological age, but all embraced the method. And, with even less equivocation than Binet, most also embraced wholesale the vision of intelligence—singular, hierarchical, unidimensional— that the 1908 and 1911 scales embodied, as well as his ambitions for the possible social roles that the scale could fulfill. Flexible in some ways, the Binet-Simon scale proved extraordinarily obdurate in others.

PSYCHOLOGICAL MEASUREMENT IN BRAZIL IN THE 1920S[1]

Ana Maria JACÓ-VILELA

UERJ – Universidade do Estado do Rio de Janeiro, BRAZIL
amjaco@uol.com.br

Abstract

The paper traces the historical context to show the specificity of the development of Brazilian psychology while discussing the notions of centre and periphery. It focuses on the measuring with psychological tests in the early twentieth century. The great cultural, political, and economic effervescence taking place in the 1920s transformed the experimental laboratories into places where psychological measurement was applied. Additionally, local laboratories of the so called "Normal Schools" were dedicated to prepare teachers for elementary education. The Brazilian Mental Hygiene League is also presented and its function is compared with that of the New School movement in relation to psychological testing. Our analysis seeks to clarify the relationship between the expanded and consistent presence of psychological measurement and the institutional support of the government, which led in many cases to a transformation of psychological measurement in something like a state project.

Introduction

Brazil entered the European universe in 1500, when the first Portuguese ships arrived at what today is Brazil's territory. Colonization left deep marks in the Brazilian way of living and thinking from there on. The production and dissemination of scientific knowledge was quite limited until the early years of the 19th century. It depended chiefly on the importation of foreign works and brief internships in the European territory, mainly, in France, taken by those interested in psychological topics. The elites were satisfied with Brazil's role as an exporter of agricultural and mineral products and as a receiver of ideas as well as manufacturing methods developed in other places. Taking this road, republicanism spread in Brazil since the second half of the eighteenth century. (Fausto,1995). It was up to the intellectuals engaged in the republican cause to reform the State in order to meet the challenges of an economically and culturally backward nation and lead it toward a civilized model of a European nation. In this sense, the reduction and/or elimination of illiteracy was considered fundamental. It is estimated that around 65% of the Brazilian population was illiterate in the early twentieth century, very different from the Argentine situation. (Fausto & Devoto, 2004).

[1] Support: CNPq, FAPERJ, UERJ.

The political and intellectual elite tried to ameliorate education because the educational system was perceived as deficient, in the sense of being archaic, artificial and based too much on memorization and physical punishment (Gondra, 2004). In the year following the proclamation of the republic, new legislation modified the teaching system (Decreto Brazil, 1890).

This brief historical contextualization is important since it points out the specificity of the Brazilian case also in relation to discussion of the notions of centre and periphery: Brazil only takes what is known as a "peripheral" position in the nineteenth century. With the creation of the first university courses a great effort was being made to reproduce the ideas and practices developed in the centre in the most "correct" way, thus seeking to become a "civilized" nation. Psychology was also part of the "group of new ideas" that arrived to Brazil (Romero, 1926): positivism, evolutionism, materialism.

The present paper focuses on texts published in Brazil at the beginnings of the twentieth century that deal with psychological measurement. Psychological measurement was practiced initially, but not exclusively, in laboratories of experimental psychology. The great cultural, political, and economic effervescence taking place in Brazil in the 1920s turned the experimental laboratories into places of psychological measurement, with the new laboratories of the Normal Schools becoming active. Meanwhile also the Brazilian Mental Hygiene League developed an interest in psychological measuring as we will see in our review of the journal "Brazilian Mental Hygiene Archives". The New School movement shared some of the aims of the League and, therefore, was open to psychological testing. Our analysis makes clear the close relationship between the increasingly consistent presence of psychological measurement and the institutional support of the government, which led in some cases to transform mental measurement into a kind of state project.

The first phase of psychological measurement

After the first psychological laboratory had been founded by Bomfim in 1906, some other laboratories would appear, most of them in the "Normal Schools" –institutions for preparation teachers to elementary schools. (Olinto, 1944/2004).

Probably the proposal for an invitation of the psychology professor Clemente Quaglio (1872-1948) was decisive for the arrival of the Italian pedagogue Ugo Pizolli (1863-1934) to Brazil, who in 1914 spent seven months at the School of Anthropology, Pedagogy and Experimental Psychology of the Escola Normal da Praça in São Paulo (Centofanti, 2006; Antunes, 1999). He taught the use of ordinary lab instruments, and argued for the implementation of a "biographical card" in schools. In Pizolli's view the teacher needs to have some psychological knowledge which permits him to distinguish between normal and abnormal children (Centofanti, 2006). The influence of his scholarship would be noticeable. After Pizolli's brief stay, the laboratory of the Normal School of São Paulo began to operate precariously. Monarcha (1999) states that Quaglio used "various measurement methods, among which was the metric scale of intelligence of Alfred Binet and Théodore Simon; he probably was undertaking the first application of the scale in the Brazilian educational field." (Monarcha, 1999, p. 252).

Hygienism –to cure an ill nation, prevention is the best remedy...

But a strong impulse for mental testing came from the Brazilian Mental Hygiene League which started to appear in the 1920s, a decade of politico-cultural effervescence in Brazil. In contrast with the beginning of the twentieth century, in which the Republic was embryonic, in the 1920s the atmosphere was one of criticism of the existing oligarchic republican model. There were revolts, such as the lieutenants' revolt, aiming at transforming the political regime and resulting in the movement known as "Coluna Prestes" – it crossed a good part of the interior of the nation between 1925 and 1927, seeking the insurgence of the people against the existing oligarchic regime. There were cultural reform movements, such as the modernist movement and the founding of the Communist Party of Brazil (1922). There was also a moment of crisis in the coffee industry and thus a moment of economic difficulties for the nation. At this point, the Catholic Church reorganized itself and united its intellectuals around the Dom Vital Center, in 1922 (Fausto, 1995).

In this context the Brazilian Mental Hygiene League (LBHM) was founded in 1923 by Gustavo Riedl, then director of the Psychopath Colony of Engenho de Dentro and a great enthusiast of hygienism, which he got to know on his travels to the United States. In 1923 the League was considered of public service by the Chamber of Deputies and, as of the following year, it began receiving financial assistance from the government.

It united professionals from different fields, members of the educated elite of the time, mainly, physicians, jurists, educators and journalists. Also one year later, in 1924, the Brazilian Association of Education (ABE) was created interested in solving the existing social problems with the help of education. Psychological testing would increasingly appear as a great auxiliary instrument in the project of "civilizing the nation", of introducing Brazil into the lifestyle of occidental civilization (Carvalho, M. A. R., 1994; Schwarcz, L., 1993). As Campos says, we are dealing with an initiative led by a generation of dedicated intellectuals, who tried to *"reinvent the nation, organize it upon new foundations and make it quickly overcome the enormous archaic obstacles that separated it from contemporary civilization"* (Campos, 2004, p. 24). The issue here is to know the "abnormal", those who happen to be degenerated in Morel's sense and, for this reason, difficult the development of the country towards a civilized nation.

In 1925, the League began the publication of the "Brazilian Mental Hygiene Archives", a regularly published periodical and the official dissemination vehicle of the hygienist ideology. There is only one article by a psychologist, "Children's mental hygiene, based on the laws of psychology" by Waclaw Radecki, Chief of Psychology Laboratory of the Psychopath Colony. This is important because Radecki was the only one among those interested in psychology at that time in Brazil that had a formal education –academic and professional– in this new field of knowledge. The Brazilians were either solely self-taught or, at the most, had taken advantage of short training courses in European psychology centers (as Bomfim and Medeiros). It seems to be reasonable to conclude that the Radecki's hiring to the Psychopath Colony is inscribed in the relevance of the psychological knowledge to hygienism.

Despite these names and departments, it is interesting to note that the authors of the first historiographic texts of psychology in Brazil rarely mention this strong presence of "psychology" in the League. Only Olinto (1944/2004) and Lourenço Filho (1955/2004) mention it, yet in a discreet manner.

The systematic use of tests began with the League, since the tests seem to correspond to the main objective: prevention. It is necessary to know the potential, the possible abnormalities –make a diagnosis–, in order to prevent maladjustments, crime, and madness. Criticisms of the earlier use of the tests by Bomfim and Alves head in this direction, since "adaptation of the tests to the Brazilian context" was important (Leme Lopes, 1929: p.70). The "translation" they performed was not enough; an "overhaul" was necessary and "[was] being conducted by the physician Ernani Lopes," future president of the League. Other texts are studies of tests seeking their Brazilian standardization, such as those by Leme Lopes (1930, 1932) and by Lopes (1931). There is much confidence in the scientific nature of the test, as long as it is used in an appropriate technical manner, as well as its ability to predict a student's intellectual aptitudes. These articles achieve an even greater objective: to clarify the need to recognize (diagnosis) the possible abnormalities, thus favouring a hygienic culture in Brazil, as pointed out by Carvalho (Carvalho, A. M. T., 1999).

Didactic support for testing

In the same year the Brazilian Association of Education (ABE) was founded, a book was edited that we consider being crucial for the history of psychological measurement in Brazil: *"The Tests"*, by Medeiros and Albuquerque (1924). He presented a didactic support for dealing with the problems of the various types of exams in commerce and industry. He introduces the "test" concept, its purpose and its importance for standardization. He describes the history of the tests, explain how to use them, while he cites the main ones giving examples. But he also discusses on intelligence, raising the question about how to measure what is unknown?

It is not sure that test applications had been made previously but it is clear that the Binet-Simon test had already been known in several of its forms. Nevertheless, the book by Medeiros and Albuquerque facilitated the dissemination of measurement tests, introducing the concept in fields that still had not acquired the perspective of standardization.

This occurred, for example, in Bahia, where Isaías Alves (1898-1968), who was trained in Law but dedicated to the teaching profession, became the main advocate of mental tests. After reading the book by Medeiros and Albuquerque, he immediately bought the books cited in it (Alves, 1930). His various activities included the translation of the Binet-Simon-Burt scale, which he discussed in his 1926 book *Teste Individual de Inteligencia (Individual Intelligence Test)*, and the proposal of using tests and experiments from other countries. He also standardized Ballard's collective test[2], which he describes in his book *Tests and School Reorganization* (1930).

Alves explains the value not only of diagnosis but also of prognosis of the Binet-Simon test. It not only helps the school to decide about the present but indicates what the student can accomplish in the future. It becomes possible to make a prediction "as to the child's future" (Alves, 1930, p. 31). But he is already conscious about the interaction with the social situation. He adds that a child with an indicative a below average intelligence (like IQ of 85) that "his scientific or social situation will be even lower, if money or protection is not able to give him a position that he will never know how to honour" (Alves, 1930, p. 36). Alves thus seems to be correct that, despite all the praise given to science in official discourses, the cultural custom of "paying favours" (DaMatta, 1985) was prevalent. It means, in Da Matta's analyses, that the Brazilian cultural habit of giving privileges to social positions by means of criteria other than merit, thus creating a culture in which the favour (and the need to pay for it is a constant practice.

Alves goes beyond the applicability of measurement to education and extends it to delinquency: the Binet-Simon test renders a valuable service in the study of delinquents, especially juveniles, who need special treatment [...] An 11-year-old delinquent with an IQ over 90 *"indicates a sure possibility of recovery, if placed in a pure and perfectly disciplined environment,"* [...] but if placed together with other delinquents with IQs of 40-70, there is *"every possibility of aggravating his*

[2] Test created by Ballard in England, considered very economical to use because only sheets of paper and pencil and can be applied collectively. It was used in Barcelona for Mira y Lopez and adapted to Argentina by Croome, Iglesias y Forgiore (Székely, 1946).

moral disorganization, even of becoming a leader of the imbeciles and cretins that make up a large part of the criminal world" (Alves, 1930, pp. 38-39).

Alves' discourse emphasizes the close relationship between the State's interest in the need for a correct prognosis in the scholastic future of the child for the correct investing. The State should invest in the construction of a new man. He even remained linked to the State even during the dictatorship established with the New State in 1937 (Rocha, 2008).

Alves was a scientist reproducing dominant ideas of his time. In 1928 he was responsible for the testing service in public schools like Salvador (Bahia). During his stay in the U.S., when he studied with Edward L. Thorndike, he commented on the results achieved. For his work he obtained his Master of Arts and Instructor in Psychology degrees from the Columbia University Teachers College. In these comments, he explains that, dividing the students into three categories (blacks, mulatoes and whites), he observed low performance on the tests of students considered black (66.1), while the best performance were the ones of the white students (86.6). Mulatoes displayed average performance (73.6). He also verified that the average IQ of the white students rose when the scores of students from private schools were added to those of public school students (this was the case for the Ipiranga High School) (Alves, 1933, p. 18, as cited by Rocha, 2008). In relation to this point, however, Alves did not innovate but repeat Roxo's classification. This physician had proved that the reaction time of alienated blacks was longer than that of whites in his doctoral thesis (Roxo, 1900).

The new school –laic, free, public education

Although since the 1920s there had already been interaction among educators seeking the transformation of education in Brazil, whose most visible consequence was the creation of the Brazilian Education Association in 1924, it was only in 1932 that the proponents of the "New Education" launched their manifesto. Headed by Fernando Azevedo, the Manifesto also boasts other signatories of prominence, including professionals that would later become highly renowned in the psychology field.

Highlighting the necessary laic, free and obligatory nature of education, as well as its public qualities –since it is a social activity–, the foundation for using measurements is in the Manifesto's main proposal: education must cease to be a privilege resulting from the individual's socio-economic situation, and we must recognize each person's right to an education "as far as his natural aptitudes will permit" (Azevedo, 1932).

Abstract

In recent years, the scientific, cultural and political French context of the first intelligence tests has been the object of systematic historical research (Carson, 2007; Foschi & Cicciola, 2006). Sante De Sanctis (1862-1935) and Alfred Binet (1857-1911), in collaboration with Théodore Simon (1873-1960), introduced their intelligence tests to the scientific community of the time at the Fifth International Congress of Psychology held in Rome in 1905. De Sanctis and his collaborators compared the two tests and used them in the training schools and asylums for children . This paper explores how intelligence testing was introduced into the Italian and, more specifically, Roman context.

In the early 20th century European context, two "experimental" psychologists, namely the Italian Sante De Sanctis (1862-1935) and the Frenchman Alfred Binet (1857-1911), understood the social value of the psychological applications and presented –in 1905 in occasion of the V International Congress of Psychology– the first intelligence tests. The metric scale of Binet and Simon's intelligence test and the Reactives of De Sanctis' test were officially presented during the V International Congress of Psychology held from the 26th to the 30th of April 1905 in Rome. Sante De Sanctis was involved in the organisation, serving as vice-secretary.

Binet and Simon (1905) both authored the paper entitled "*Méthodes nouvelles pour diagnostiquer l'idiotie, l'imbécillité et la débilité mentale*" that was included in the third section dedicated to abnormal psychology. The section was presided by Enrico Morselli (1852-1929). It is necessary to add that Binet and Simon's paper was presented by Henri-Etienne Beaunis (1830-1921). This section also included a paper by De Sanctis, entitled *Su alcuni tipi di mentalità inferiore* [About some types of mental inferiority], which contains the first version of his psychological tests (De Sanctis, 1905).

Binet and Simon's metric scale of intelligence

On October the 4th 1904 Joseph Chaumié (1849-1919), Minister of Public Education and the Fine Arts, created the inter-ministerial commission for the education of abnormal children. The government of Émile Combes (1835-1921) entrusted the presidency to Léon Bourgeois (1851-1925), a mason, lawyer and radical theorist. The commission was established to verify whether or not the laws published by Jules Ferry (1832-1893) on free education (1881), as well as secular and mandatory education (1882), had been applied to abnormal children. Bourgeois called upon Binet to become a member of the commission, which had grown so much that it had been subdivided into several sub-commissions: the first was in charge of carrying out a study on the number of “abnormals” present within the French national territory; the second sub-commission –defined as *sous commission pédagogique des anormaux*– was responsible for studying the measures necessary in order to assure that developmentally delayed and instable children were provided with the benefits of an education. This comprised an analysis of the institutional and pedagogical questions associated with “abnormal” children. Binet was one of the most active protagonists of the second sub-commission, for which he was the author of the final report on abnormal children (see Vial & Hugon, 1998).

The experience gained through the inter-ministerial commission supported the development of the first version of the intelligence test known as *Echelle Métrique de l’Intelligence*. Binet, in collaboration with Théodore Simon, worked together in developing the test. The construction of this instrument was facilitated by the pretext of responding to the social demand created by the schooling of abnormal children. Their low level of performance in normal classes suggested the need for alternative forms of education.

But what was meant by inferior states? What theory of abnormality did Binet adhere to? The author, in particular, invoked a theory of partial development as the cause of abnormality. In fact the development of the abnormal child followed irregular and partial processes that varied from individual to individual. Nevertheless it did not exclude the possibility of substituting the deficits in some sectors with others that were better developed; in consequence a “psychological” intervention intended to increase the deficient development sectors of the abnormal individual was retained to be possible.

It should be noted also that the *differential diagnostic method* developed by Binet and Simon should, in the first place, have established the *intelligence level* –a notion that in 1908 was substituted by *mental age*– of abnormal children, making it possible to place the children in the following objective and verifiable diagnostic categories: idiocy (inferior level of intelligence), imbecility (intermediate level) and weak mind (less severe and lighter level). In the second place, the method made it possible to objectively distinguish between a normal and an abnormal child.

In general, the differential diagnosis is composed of three principal methods: 1) the medical method, 2) the pedagogical method and 3) the psychological method (Binet & Simon, 1905b).

1. The *medical method*, which was very long and laborious, sought to identify intellectual inferiority by means of anatomical, physiological and pathological signs.
2. The *pedagogical method* consisted of the assessment of a subject’s intelligence on the basis of the knowledge acquired by the student in an educational setting.
3. The *psychological method*, which in practice used the Metric Scale of Intelligence, sought to determine the *abnormal* child’s level of cognitive functioning, comparing this level with what was considered normal for the majority of children, with apparently healthy development.

Binet and Simon’s conclusions held that one should consider the medical method only capable of revealing *possible* indications of mental delay. Hence it should only be used to confirm the psychological diagnosis. They also argued that the pedagogical method only managed to demonstrate *probable* signs of abnormality because: *“The intelligence of each of us must solely be judged through intellectual manifestations”* (Binet, 1910, p.17). The two authors’ propensity for the psychological method, specifically the Metric Scale of intelligence, was evident. For them it was the only method capable of objectively establishing the intellectual level of abnormal children, managing to identify *certain* signs of mental retardation on the basis of the degree of the gap in respect to a statistically constructed norm (Cicciola, 2008; see Lombardo & Pedone, 1995 for models of normality and pathology in the history of psychology).

De Sanctis’ reactives

The tests constitute a category of instruments that have for a long time characterized the psychological disciplines and, in part, continue to characterize them today. Yet very few studies exist that seek to reconstruct the origins and the development of these applied instruments. This is also the case for the historiography of these instruments in Italy. This paper will explore the tests developed by De Sanctis, and known as “De Sanctis’ Reactives”, that the author applied above all in the context of his asylum schools founded in 1899 with the aim of grading the mental insufficiency of children and adolescents.

Sante De Sanctis –who was trained at the School of Medicine of the University of Rome *La Sapienza*– was a student of Giuseppe Sergi and a post-doc student at the Salpêtrière of Paris. De Sanctis held the first professorship in experimental psychology in Rome. Historically speaking, he was clearly a leading figure at the beginning of the 1900s within the sciences applied to behaviour in the context of the renewal and the modernization of the city of Rome and the Italian state, which had recently been unified in the institutional form of a constitutional monarchy. There were two additional versions of the test developed by this Roman psychologist –supported by his pupils–presented in 1905. The second version contains only slight modifications in respect to the first and continues to be applied only in the asylum schools. The last version, dated 1914 (see De Sanctis & Bolaffi, 1914), is characterized by an increase in the number of degrees of mental insufficiency and partially includes the modifications proposed by Postowsky, a Russian scholar for which there is only a feeble trace in the current historiographical literature (Ceccarelli, 2002, p. 42; see Cimino & Lombardo, 2004).

In the 1905 version presented at the Congress, De Sanctis introduced his reactives in this manner:

> The series that I propose is applicable to all phrenasthenics, as long as they are not under the age of 7 and as long as they are calm; it is worth noting that this should not be applied if not during *periods of utmost calm and when the subject is in full health* and not when the subjects are in a bad mood, emotionally disturbed, tired or feeling negative, in a tantrum or of a similar spirit. *Choosing the moment for the application of the reactives in order to obtain from the reagent* optimal *responses*; this is the difficulty that only a capable master or an experienced doctor will know how to overcome with full success (De Sanctis, 1905, p. 586).

De Sanctis proposed the following exercises in the first version of his test:

1. Give me a ball (measure of response time);
2. Which ball have you given me? (measure of response *recognition*);
3. Do you see this piece of wood?: well then, find the pieces of wood that are the same as this one in the middle of all of the others that you see;
4. Here's a pencil for you; mark all of the equal pieces of wood that you saw earlier on this on carton (*recognition* and the indication of the figures is achieved);
5. Here are once again lots of pieces of wood of the same form as those that you just indicated on the carton; look at them carefully, then tell me *how many there are*, which of these is the *biggest* of all of them, which one is *farthest* from you;
6. (One places the diaphragm in such a way that the reagent no longer sees the pieces). And now tell me: do you think that the *largest* objects are necessarily the *heaviest*? Are the *most distant* objects really the *smallest*, or do they only appear to be smaller than the closer objects? (p. 586-587).

De Sanctis recommended this series be applied in accordance with rigorous rules aimed to indicate four degrees of mental insufficiency (no insufficiency, mild insufficiency, average insufficiency, high insufficiency).

Amongst the other things the problem of training for teachers emerged. It is not by chance that the teaching of experimental psychology was a fundamental subject in the pedagogical schools proposed by Luigi Credaro (1860-1939), a pedagogue and politician.

The 1914 version was published in *Infanzia Anormale* [Abnormal Childhood] and edited by De Sanctis and his collaborator, a teacher at the Casa di Cura e di Educazione [House of Care and Education) “Villa Amalia” in Rome, named E. Bolaffi. The book describes the three versions of the “battery” of tests developed by De Sanctis, beginning with the 1905 version. In the 1914 version the test was comprised of six sub-tests that constitute a real “operational series” of exams with an established sequence, verbal deliveries and a complete description of the material used.

De Sanctis' test, like that of Binet-Simon, consisted of tasks ordered by increasing difficulty. The substantial difference consists in the different objectives between the two tests: De Sanctis did not have the intention of measuring the normal mental age and comparing it with the pathological. De Sanctis' test measured the intellectual deficit and was capable of taking a snapshot of the difference in the level of mental capacity that could be applied to the healthy and the abnormal in order to verify whether or not there was difficulty in learning that necessitated an intervention involving psycho-pedagogic methods.

Conclusions

Psychological historiography highlighted the role of the approaches involving anthropometric and craniological measurements as precursors to later investigations with the help of mental tests.

As we have seen, 1905 can be defined as the year in which the psychological study of the individual by means of mental tests really started. Binet's test was, in concrete terms, the result of a program of craniological and anthropometric research that had led French psychology to exclude methodologies for measuring intelligence based on the correlation between body measurements and corresponding success in education (Foschi & Cicciola, 2006; Cicciola, 2008). The same Sante De Sanctis first supported and then distanced himself from a positivistic and anthropometric conceptualization that in Rome was represented by his “master” Giuseppe Sergi) (Lombardo & Cenci, 2004).

Both in the Parisian and Roman context, precise transformist conceptions of human nature were also well rooted and it is on these that Binet and De Sanctis constructed a conceptualization of “educability” with the aim of the intellectual recovery of children with mental problems as well as the poor and marginalized. In this sense the mental test in France and

Italy would have primarily come to be used in public education; mainly pursuing an educational and progressive aim. The individualization of "delayed" children was the first step for providing them with a special education that was useful for their training, in order to rebalance them with the help of a psycho-pedagogic intervention. The aim was to give these children a chance although nature had not given them equal opportunities. One notes a difference with other contexts. One is the American in which the tests were used with the aim of eugenic selection rather than to make it possible to offer children a potentially helpful intervention (Carson, 2007). Another is the Spanish, where the tests were proposed to be used for the promotion of teachers (Mülberger, 2010).

The situation in Italy was similar to the experience of the third French republic. The objective was primarily that of making primary education free, open and mandatory for all, including phrenasthenic children or those with other types of behavioural problems. At the beginning of the 1900s the use of mental tests was above all applied in a psycho-pedagogic context. Its use in psychiatric clinics was, from the beginning, above all for precision and calibration. After the first decade of the 1900s the use of mental tests in Italy underwent a sort of progressive medicalization (Lombardo, 2007). Between the 1800 and 1900s the intelligence tests were used in "special schools" (e.g., asylum schools, educators, differential classes) and then rudely entered medical clinics. From the 1920s on the tests were introduced in neuropsychiatric practice with children with the goal of diagnosing "mental retardation".

In the Italian, medical, psychological, and pedagogical cultural context that characterized the entire 20th century, the conviction was held that the test was not a *passe partout* instrument that could be applied like "a thermometer". The test was always used to complete the clinical interview with specific populations and with practical aims. Psychologists and doctors shared the conviction that the tests did not pass the test-retest reliability assessment for the average subject and that this evidence was adequate in order to promote a use of the mental test just in association with a systematic multidisciplinary clinical observation and interview (Ceccarelli, 2002).

HISTORY OF PSYCHOLOGICAL MEASUREMENT. RUSSIAN CONTEXT IN THE 1920S-30S

Irina Léopoldoff-Martin
FAPSE – Faculté de Psychologie et des Sciences de l'Éducation, Université de Genève, SWITZERLAND
irene.leopoldoff@unige.ch

Abstract

The rising of the experimental research at the turn of the 19th century is mostly focused on new objective methods and the same interest is shared by scholars in Russia as in Europe and USA. The historical period we evoke begins when science has just discovered the child as a major object of study. Medicine, law, and then all the young human sciences seize it (Ottavi, 2001) to build knowledge about human development. At the time where boundaries between sciences were not clearly established, all of them were on the way to investigate in the same new field: the child and his development. However, specificities in the development of psychological and neurological disciplines will appear in Russia with the First World War and then, will increase with the huge social changes induced by the October Revolution in 1917. If the history of psychological measurement concerns also adults, in our approach, we focus deliberately on the psychological tests applied to children and closely connected, like elsewhere, to the question of education. The Soviet psychological measurement is mainly linked to pedology and its singular fate (Fradkin, 1990; Etkind, 1992, 1997). Pedology, also called "child study", supposed to be the solution to solve the numerous problems of education in the new socialist society, was also the first science to be officially forbidden in Soviet Union in 1936. Psychological measurement was indeed massively applied to children in various circumstances which we are going to describe further through samples collected in the journal Pedologija, the official organ of Soviet pedology from 1928 to 1932. Lev Vygotskij's point of view on the matter will contrast this historical context.

A new science for a new society

The educational stakes in the 1920s in Soviet Union were of a rarely equaled large scale. After seven years of international conflicts, revolution, civil war and famine (1914-1921), one priority was the reintegration into society of hundreds of thousands of children and teenagers left on their own (*bezprizorniki*), by these sequential events, in a country itself disintegrated, weakened and in search of marks. A project of fast and radical reconstruction had to be started, compatible with the ambitions of the young socialist nation. Pedology served the socio-political plan with expectations of an efficient education policy. In quest of solutions, it afforded this science a direct experiencing to the creation of a "New Man", linking theoretical research on child development to practice in the educational system. Authorities expected from pedology a fast progress to design a child of a new type according to their ideology. A new science calling for new practices, pedology was probably the discipline that used "objective" psychical and physical measurement on such a large scale. The laboratory for experiments took the size of the nation. The revolutionary situation, the strong social needs for knowledge on the child and perhaps also an overt context for a new discipline are the original components of the educative policy in USSR, during the 1920s. After 1917, all sciences in Soviet Union are reconsidered on the same bases: an objective materialistic dialectical science, fighting against the idealistic, mechanistic roots of traditional science. Education for the new nation must necessarily be distinguished from the tsarist one and from the system in place in capitalistic countries.

A controversial issue

This experimental and pedological adventure in Russia starts mostly with the personalities of Vladimir Behterev (1857-1927) and Alexandre Nečajev (1870-1948) in Petersburg, Gregori Rossolimo (1860-1928) and Mihajil Bernstein (1894-1975) in Moscow. The central place was given to explore qualitatively and quantitatively the child potential. One of the main reasons for this decision, and it is still an interpretation nowadays, was the abusive way the pedologists used the testing. Before the First World War, experimental pedagogy and experimental psychology used to work very closely together and in connection with Western scholars. According to Helene Antipoff, Claparède's Russian assistant in Geneva, before Nečajeff, pedagogical psychology (or experimental pedagogy) was a "terra incognita" in Russia, considered like a ridiculous and harmful matter for Russia. For him, a drastic reform in schools was necessary in connection with experimental psychology. The reception of his first book[1] (1901) was much criticized having connected pedagogy with psychology.

An objective science for Soviet pedology

The independent way taken by Soviet pedology became an originality whereas elsewhere, it was incorporated in other sciences. Russian pedologists agreed on the fact that the science of the child development was an objective science as well as biology, thus rejecting the empirical orientation of the first pedologists, in favor of a subjective, introspective science or in the line of Wundt's experimental psychology. Psychological measurement became a trend for child testing at school to evaluate their intellectual abilities, but also often used to compare children according to their cultural environment and family upbringing. Some of the leading pedologists of the early soviet period like Pavel Blonskij (1884-1941) or Mihajil Basov (1892-1931) expressed both their enthusiasm and fascination for testing methods. Blonskij, in the preface of the 1928 book *Tests: Theory and practice*, envisaged a promising future to the method. He claimed that "Tests are more than a method of control; they are an instrument of rationalization of school". Basov in the same book gave his enthusiastic opinion on the matter: "I think the sometimes sharp criticism of the testing method will bring finally not to the reversal, not towards the abolition of this method, but on the contrary, towards its consolidation and its assertion in the defined borders, where, obviously, its legitimacy and the reason to be applied will be proved"[2].

Russian contribution to psychological measurement

If Binet's tests were very often used by Russian scholars, Rossolimo, mostly known as a neuropathologist created a method of psychological profiles compared at that time worldwide with Binet's method. His test was also used abroad. He conducted his main research on children with psychical diseases and abnormal behavior, studying age specificities in child behavior. In 1911 he opened in Moscow the first institute of child psychology and neurology working on nervous diseases. He determined a direct correlation between behavior and the development of psychical functions. His profiles' method was mainly a quantitative measurement of the various psychical functions of personality. He itemized 22 functions. The results of the test were put on a graphic, representing a curve of a given profile of personality. However, Soviet pedology was not a homogeneous science, and had difficulties to move from a dualistic point of view. For the two main tendencies which were confronted in their theses, the dichotomy between biogenetical and socio-genetical foundations was obvious. One overevaluated the influence of heredity on development of child, whereas the other neglected it by considering that only the transformation of the social environment allows a radical modification of the development of the child, by adaptation. The socio-genetic orientation was supported by the authorities' ideological point of view. Vygotskij's historico-cultural orientation was very marginal, at that time.

Experimentation and testing through the journal *Pedologija*

This journal was born in 1928, after the first panrussian congress of pedology, with the support of some major politicians involved in education policy, like Nadežda Krupskaja and Anatoli Lunačarskij. *Pedologija* was published until 1932. The description of the contents of *Pedologija* is not exhaustive in the modalities granted for this article, because the whole magazine over five years counts several thousand pages. Chronicles and thematic directory of *Pedologija* constitute a considerable source of precious empirical and statistical information and allow showing concretely what was measured in researches about child. Many empirical researches were of quantitative nature, founded on the analysis of statistical data. Numbers of them were based on questionnaires, Binet's tests and Rossolimo's profiles. The anthropometrical and psychometrical tests were frequently applied, and reflected the biogenetic and socio-genetic points of view. The examples bellow were chosen to illustrate the different types of studies elaborated during this short period in pedology.

Ethnographical type study

The multiethnic dimension of USSR opened an emancipation policy for the minorities. It was developed during the 1920 idealistic period, followed by a realistic bureaucratic control after 1930[3]. In 1922 Russia became the Union of the Socialist Republics, composed by 15 republics and some autonomous territories, the *kraïs*. The Soviet policy on nationalities in the 20s and the beginning of the 30s, was placed under the sign of the *korenizatsija*[4], a short period during which the new political regime tried to reverse the effects of the Russianization undertaken during the Tsarist period on non Russian populations. After 1930, Stalin intensified the Russianization of the minorities, and tried to impose a single culture[5]. In 1930, many scientific expeditions were sent to the Caucasus, Central Asia, Siberia, and Mongolia. The field of scientific research was not limited to ethnography, and opened a field to pedologists in connection with educational psychology. *Pedologija* published a special issue almost entirely devoted to the first research results mainly about women and children of national minorities, (1930, 2). In each case, a Binet-Simon test was applied, sometimes associated to the Rossolimo's psychological profiles test. Anthropometric measurements were also applied to a broad scale with children of the various Republics. Comparative studies with the Russian children were carried out.

Biogenetical type study

S. Kacenelson's and V. S. Brodovskaja's study entitled "The characteristics of the children in the first degree in work school" (*Pedologija*, 1930, 3, 350-368), represents an example of the biogenetic stream of pedology. This is a medico pedological type research, bearing on 1,045 children admitted in the first group of 12 elementary schools (504 boys and 541 girls). The age of the subjects varied from 7 to 10 years. The authors took account of the children social situation; hereditary influences; their physical development; their health condition; their psycho-neurological status (giddiness, speech difficulties, knee jerk, pupil reflex, etc.). The mental age was measured according to Rossolimo's reduced scale. They carried out a compilation of statistics starting from the results of their observations, and drew some of the following conclusions: as the children who enter to the school represent a heterogeneous mass from the biological and social point of view, the composition of the first groups of the elementary school must be only based on one preliminary pedological investigation. In addition, one should not make compulsory teaching starting from seven years of age; however, the seven year old children wishing to attend school could be allowed. For slower children, it was mentioned as essential to create special groups with an individualized teaching.

Sociogenetical type study: Social organization abilities

S. Zalužnyj study (*Pedologija*. 1929 4, 478-489) on child collectives is an example of a sociogenetical type research. Carried out in Ukraine, in 212 elementary and secondary schools, it consisted of testing the class social organization. Each class had to fulfill different tasks successively, such as to elect a delegate for the municipal school conference, to organize quickly small teams for collective works or menage a project of a school festival. According to an official report taken by teachers, marks were attributed to the results on a scale of 5 degrees, the results were showing the progress from class to class: The class, the age, the number of groups tested were the base of an average of marks, an average of variable and an average of time: The coherence of the tests was evaluated by correlation of par and odd tests with the application of the Spearman-Brown's formula. Which deductions can one draw from these tests? The author affirmed that the results gave an account of the children's problems of organization and discipline between them. The children found difficulties for planning

[3] For example, the obligation for all national minorities to put down their origin on their identity papers.

[4] literally: 'rooting'.

[5] One school, one language.

their work by group; groups were usually formed by genders. The author didn't give any precise result, and remained cautious by concluding that it would be necessary to continue the research to study the problem of the disturbing elements.

Vygotskij's specific point of view

Vygotskij is not very known as a pedologist, however the child development became his main topic after 1927. He didn't share his colleagues' enthusiastic point of view on quantitative methods.

Vygotskij, in several texts, expressed clearly that psychology and its methods didn't satisfy him. In the last years of his life, through pedology, he developed a general science where the theory can't be separate from practice. It is in practice that theory could find a validation. In the *Significance of the crisis in psychology* (1927), Vygotskij's diagnosis was explicit: between an idealistic approach following a subjective way, and a mechanistic approach reducing the psychological phenomena to a biological fact, the question was to find a monist and dialectical way, which takes account of the material base of the psychical processes without reducing them to simple biological processes. One major element of the crisis was the difficulty to articulate theory and practice.

In his text on "Pedology and close sciences" (1931), Vygotskij[6] analyzed the reason of this stillborn discipline in Western countries. In Vygotskij's opinion:

> "Pedology should be based on the objective reality of the unique process of development which is its object. It can't be build on the field of the metaphysical, logico-formal point of view of child development which only allows a mechanical association of the different aspects of development, nor on the field of a dualistic point of view of human nature, closing the way to the study of the real unity represented by the process of child development. It is exactly for this reason that pedology as a particular science is almost dead in the West and in America".

If we follow Vygotskij's reasoning, here, the essential basic unit of pedology is the child, composed of multiple internal systems, in his relationships in a particular environment. By taking the child as a whole, according to Vygotskij, it allows a decomposition per unit, by keeping the characteristics specific to the child which are as well internal (hereditary) and external (social milieu), to reach at last the particular complex phenomena which compose them. The starting point cannot be the understanding of isolated facts. For Vygotskij, it was necessary to start from a synthesis to understand its multiple aspects, and he called in question the validity of the interpretation of results obtained by quantitative methods:

> "The element taken separately does not have a value for analysis of a pedological type. For example, to separate hydrogen and oxygen from a molecule, makes lose the characteristics of the unit. Consequently, the core is not the element, but the unit, i.e. the relation of a factor of the milieu with the characteristics of the child. If we find such a unit, it will preserve in it what is present in the development of the language as a whole, i.e. the relationship between factors of the milieu, individual factors, and factors rooted in the characteristics of the child" (1933/34 1996, p. 45).

Vygotskij argued that by the will to show relations between everything, one doesn't explain anyyhing at all anymore. He expressed his mind very clearly:

> "But finally, looking for general links instead of a clear picture, it is an absurd confusion which appeared. All was related to all: memory with capacity, intellectual development with the acuity of sensory functions, growth, understanding, the way of eating, and the success in arithmetic" (p. 58).

For the five-year scientific plan, Vygotskij wrote in 1929 a report on the detailed program planned for research concerning national minorities and preparing with Luria an expedition in Central Asia (1931-1932). In this article, Vygotskij was clearly guarded about the use of tests and their compatibility with cultural diversity. They would owe, according to him, being adapted to the specific context of each country, according to its formal and informal system of education. In his opinion, tests in themselves cannot be objective indicators of the intellectual development. He claimed that the standard tests used in pedology do not have a universal value and can sidestep the issue of a research. He conceived the development of the child in an ecological and cultural context, and recommended a field method to study it. The point was to understand "the child as an integral part and natural product of his specific milieu, in which he lives and develops" (p. 370). It is by taking into account these factors that it will be possible to find some universal characteristics of children development. By considering the child cultural environment, his aim is to evaluate the effects of a general system of education[7] on the development. Luria's expeditions in Uzbekistan to which Vygotskij did not take part for health reasons, aimed to validate this hypothesis of the schooling effects on the higher mental functions (Van der Veer and Valsiner, 1991). The assumption was that a

[7] Unified in USSR for ten years (1919-1929).

qualitative change was to be produced by education, and to be observable in contexts where the development of the higher mental functions were worked out by other cultural means and led to different results. The first study was based on the observation of adults, the second included children. According to Luria[8], that field research was carried out by his 14 collaborators team studying 11 main topics, out of 600 people: 1. thought as a function subjected to historical changes (and namely, the process of word usage, deduction, comprehension of metaphors and symbols, logical thoughts, etc.) 2. the structure of individual psychological process (in particular, perceptions: the perceptions of form and color in connection with visual thought, optical geometrical illusions, drawings, the features of remembering, counting and so forth).

For an estimation of child mental development, Vygotskij chose a qualitative method: the instrumental method he was working on through the historico-cultural theory. We can call it instrumental method, says Vygotskij (1928), "as it is based on the discovery of the instrumental functions of the cultural signs of the behavior and their development, based in experiments on double stimulation" (p. 75). "This method is not only the key to understand the higher forms which appear in the development process of the behavior of the child, but it is also an acquisition for the practice, education and secondary education."

The criticisms of pedology 1932-1936

Pedology was the first science whose destiny was determined by a political resolution (4th of July 1936 Decree), proclaimed illegal and considered as a "pseudo science" without any scientific debate. Books censured, authors persecuted. Some contradictory opinions about the pedologist's role were spread around: a great popularity in schools, in their work in cooperation with teachers, to solve problems of learning (Fradkin, 1990), or just at the opposite manipulation, ideology, with no connection with reality (Berelowitch, 1990; Ewing, 2001). The problem with testing can be explained by the incompatibility between stalinian ideology and the tests revealing some individual differences that could be explained only by a heterogeneous social context, and the socialistic environment was supposed to be homogeneous, without different social classes anymore. Fradkin (1990, p. 204) confirmed this thesis and underlined the virulence of the attacks against pedology, which is explained by the incompatibility of all the scientific approaches whose object was the child development. The tests will be forbidden until 1970, (Avanesov, 2000), and pedology has had no official rehabilitation until now.

Conclusion

After 1936, Soviet Human sciences were extremely reduced. Soviet psychology came back on the international stage with the figures of Vygotskij, Luria and Leontev, about 30 years after Vygotskij's death in 1934. Etkind (1992) was concerned with the effects on a population, when a science is forbidden for such a long time. But we can ask the opposite question. Did Psychology and Human Sciences develop since the period we spoke about in countries where they had the opportunity to progress on child development as a support for a better education with quantitative methods?

THE ADOPTION OF NEW TECHNOLOGIES BY GASWORKS IN SPAIN

Francesc X. BARCA-SALOM, Joan Carles ALAYO MANUBENS
Universitat Politècnica de Catalunya, Barcelona, SPAIN
francesc.barca@gmail.com
joan.carles.alayo@upc.edu

Abstract

The technology of gas production for public lighting and domestic and industrial uses has become obsolete. The replacement of coal gas by natural gas resulted in the abandonment of distillation and physical and chemical depuration technologies in favour of extraction and distribution processes.
The production of coal gas contains the germ of renewal because of the need for frequent changes due to the deterioration of retorts. As a result, iron retorts were replaced by ceramic ones. Their position changed from being horizontal, tilted, and finally vertical. In order to boost production, the retorts were enlarged before being replaced by chambers. Another change in coal gas production concerns heating, i.e. by coke or tar combustion or by gas producer. Subsequently, new methods were introduced in order to obtain town gas by means of mixing blue water gas and carburetted water gas with coal gas. The decade of the 1960s marked a trend towards a new technology of gas production: cracked gas. This process replaced coal by oil as a raw material, giving rise to a cleaner and more chemical system of production.
This paper provides a preliminary approach to the evolution of technologies of gas production at fifty gas works in Spain. To this end, an attempt is made to gather dispersed and heterogeneous information in order to shed light on the evolution of technological change in the cities where this took place.

In August 1842 Barcelona became the first town in Spain to be lit by gas. After Barcelona, gasworks were built in other towns. In 1861 there were 29 factories in operation. Statistics concerning manufactured gas in Spain first became available in 1901. In order to establish the technical characteristics of these factories and their importance in industry, we have analysed the statistical data published between 1901 and 1933 by the Ministry of Finance, and we have reproduced the same analysis using the data for the period 1940-1960. In the latter period, gasworks in Spain may be divided into six groups according to the volume of production. We can observe that there are considerable differences in evolution, i.e. there is a marked decrease in the number of factories and a significant rise in the production of gasworks, especially in Barcelona and Madrid.

This paper is structured around two sections. In the first one we have analyzed what was the evolution of gas technology based on the distillation of coal and we focused mainly on the production phase, i.e. in the ovens. Secondly, we have analyzed the gasworks established in Spain in order to identify which technology had been applied and how this process had happened.

The technology of gas production

The most utilized system of gas production consisted in distilling coal in retorts by heat. The gas obtained was composed of hydrocarbons necessary for lighting, and also of unwanted substances such as hydrogen sulphide, ammonia vapour, water steam and tar.

Distillation in the retort produced coke as a by-product. The gas obtained was purified by condensation, washing and chemical processes before storage in gasholders and distribution to consumers.

The technology of gas production may be divided into six phases: 1) Directly-fired ovens; 2) Recuperative ovens; 3) Ovens of intermittent carbonization: 4) Ovens of continuous carbonization; 5) Water gas production; 6) Cracked gas production.

In this paper, we focus on the first five phases up to the year 1960. All the methods used, in principle, the same technology based on distilling coal gas or similar products.

The first retorts were cylindrical made of cast iron 1.80 m in length and 30 cm in width. They only lasted 8-10 months, after which it was necessary to replace them. In 1828 a patent was taken out on a refractory clay retort that was cheaper and lasted 2-3 years. This retort was subsequently modified by constructing one large retort using refractory bricks. However, the most utilized oven was the one of 3, 5, 7 or 9 ceramic retorts between 2.10 m and 2.70 m long, with a D shaped section, 40 and 55 cm wide, and directly fired by coke combustion.

Coke was the fuel used to achieve the high temperatures required in the distillation of coal. However, in some cases tar was employed. George Anderson designed an oven for using tar and coke. Subsequently, injectors were also employed. The Siemens brothers designed an oven heated by gas generated in a gas producer in which the lean gas was obtained by subjecting the residual coke to a high temperature air stream. The heat produced in the gas producer and in the oven was recovered in a recuperator or a regenerator.

The incorporation of gas producers to heat the retorts was undertaken in two ways. One way consisted in taking advantage of the replacement of the retorts in a directly-fired oven to use the combustion chamber in which to install a gas producer. This was the case of the Parsy oven. The other way involved implementing new technology such as Lachomette ovens. The Parsy oven had a gas producer and a recuperator placed in the small space that was previously used as a combustion chamber. For this reason, the gas producer had to be horizontal and the recuperator small.

The gasworks at Dresden used the Hasse-Didier oven, in which the gas producer was outside the oven and in which the primary air was heated by double walls that contained the ducts. The other model was the Lachomette oven, which was patented in 1889. This oven consisted of a gas producer made of refractory material with a grill placed perpendicular to the gas outlet.

In 1909, the use of tar in a gas producer was endorsed because of its low cost. Hovine designed an oven, similar to the Lachomette oven, equipped with a device that allowed the use of tar. Subsequently, this oven incorporated a tar injector. One example of this was the Echinard oven.

In the last decade of the nineteenth century and in the first decade of the twentieth century three new methods of coal distillation were introduced to meet the challenge of electricity: 1) Ovens of intermittent carbonization in vertical retorts, 2) Ovens of continuous carbonization in vertical retorts, 3) Ovens of inclined chambers.

Traditional distillation ovens were included in the group of ovens of intermittent carbonization. Nevertheless in 1885, in the Compagnie de Gaz de Reims, the idea of fitting 6 m long retorts inclined between 32º and 35º in an oven was conceived in order to facilitate the descent of coal under its own weight.

In 1905, ovens of vertical retorts 5m high were built in Berlin. The oven distilled coal for 10 or 12 consecutive hours. The charging and discharging were carried out mechanically. One example of ovens of intermittent carbonization was the Klönne oven, which was equipped with between 3 and 6 vertical chambers.

In 1907, Dr. Reis in Munich built ovens of inclined chambers that were commercialized by the Klönne Company. These ovens resembled those built in the United States to produce coke, the residual gas being used for lighting. Another type of oven that had horizontal chambers was manufactured by the Koppers and Klönne companies. These ovens consisted of parallelepiped chambers and occupied less space than the inclined chambers of their rivals.

To accomplish continuous carbonization, coal had to be introduced and coke extracted without interrupting the process. In 1903, Harold Woodall and Arthur McDougall Duckham tested continuous carbonization, but the industrial application was not implemented until the end of 1907 owing to the difficulty of obtaining the high temperature necessary for distillation.

In 1908, William Young, John Glover and Samuel West devised in Manchester another oven of continuous carbonization. This model had four retorts about 6 m long in square sections with rounded angles, narrower at the top than at the bottom. The main feature of this oven was that it was heated by ten horizontal ducts (placed one on top of the other) that crossed the retorts transversally.

If water vapour passed over incandescent coal a gas consisting mainly of hydrogen and carbon monoxide was produced. This gas came to be known as water gas. The reaction was endothermic, i.e. heat is absorbed leading to a decrease in temperature, which terminates the reaction. Therefore, water gas producers worked in two stages. One stage, known as blow down, consisted in introducing an air current through the coke to produce blow gas to increase the temperature. The other stage, known as gasification, consisted in passing the vapour through the coke to produce water gas.

There were two kinds of water gas producers: one involved recovering the heat to increase both the air and the steam. The prototype of this producer was the Tessie of Mottay model and was used to produce water gas without carburetting but it could also be subsequently carburetted. The German model Dellwik-Fleischer was based on this type.

The other type involved the use of heat to decompose oils in order to produce carburetted water gas directly. The model was the Lowe producer, on which the Anglo-American Humphrey and Glasgow producer was based. There were other models that required regenerators like the Krammers & Aats from Germany, which produced complete combustion or the Strache from Austria, which resulted in incomplete combustion. The Dellwik-Fleischer producer had a dual circulation of vapour in both directions (up and down) that favoured gas production. The blow air entered from below and was driven by a fan. The Humphrey and Glasgow producer consisted of three elements: a gas generator, a carburettor and a booster heater. During the blow phase, the gas produced has a high of carbon monoxide because some of the air returned to the producer to burn the parts that had not undergone combustion. In the gasification stage blue gas passed through the carburettor under a shower of oil. Other models of water gas producers were Tully from England and Rincker & Wolter from the Netherlands. These models were characterized by the decomposition of the oil that was cast directly over the incandescent coke. Water gas was first manufactured in the USA, where it accounted for two thirds of the gas consumption. However, in Europe its toxicity and its lack of smell were used as arguments by the proponents of coal-gas to prevent its production.

The gas industry in Spain

The evolution of the gas industry in Spain may be divided into five periods from its beginnings in 1842 to the 1960s, when coal gas production was replaced by cracking: 1) Early period (1842-1860). 2) Period of expansion (1861-1890). 3) Period of awareness of the need for technological change (1891-1921). 4) Period of consolidation of technological change (1921-1938). 5) Period of autarchy (1939-1960).

In April 1846, the gasworks in Barcelona was supplied with 10 ovens, two of which were equipped with 5 cast-iron retorts, and 8 ovens of only one retort made of refractory bricks. We suspect that a small technological change was taking place in this gas plant, i.e. iron retorts were being replaced by ceramic retorts. Subsequently, other gasworks in Valencia (1844), Cadiz (1846), Santander (1853), Alicante (1854), Reus (1855) and Valladolid (1858) manufactured coal gas in directly-fired ovens. This demonstrates that the technology using directly-fired ovens of 3 or 5 horizontal ceramic retorts had been adopted in Spain.

The case of the gasworks in Figueres should be noted because the gas was produced not from coal but from fat obtained from washing wool. The manufacture of this gas was known as the composite waste gas system, which corresponded to a patent granted in 1858 to a Frenchman, Alfons Humbert, and to Antonio Escubós from Barcelona. In the explanation of the procedure, the authors made it clear that the patent involved only the production of fatty substances to replace coal but did not involve changes to the equipment used in coal gas production. In 1880 the composite waste gas system was replaced by a new plant outside Figueres using the traditional method. This system, which was patented by Humbert, recalls the method subsequently devised by Enric Hirzel in Leipzig in 1863. Hirzel invented a simple and economical method to separate fat from soapy water when washing wool (which is termed Swint) and began to distil this product. The Humbert method was also adopted in Manlleu and Vic for 200 gas lights but was eventually replaced by coal gas manufactured in directly-fired ovens.

Humbert gas was not the only unconventional method of gas production. There were two other cases: Arbós gas and rich gas. The former was attributed to Jaume Arbós (1824-1882) chemist and priest. Between 1852 and 1867, Arbós took out five patents on the manufacture of gas and on a suction gas producer applied to engines.

Jaume Arbós obtained gas from a producer without retorts using charcoal and other carbonaceous substances.. The Arbós gas was implemented in Vilafranca del Penedes and in Badalona in 1864.

Other cities opted for systems that distilled mineral oils or hydrocarbons. This was the case of Blanes in 1881 where it was installed a Rieber and Gruner device to produce rich gas. This gas was, like that produced by Humbert, a type of oil gas obtained in this case not from fat but from the decomposition of hydrocarbon liquids and shale oils subjected to heat. The town of Palafrugell followed the example of Blanes in 1882. Another factory in El Ferrol using the same Rieber and Gruner method as in Blanes was set up.

We call the second period, the period of expansion because the number of gasworks in Spain underwent a fourfold increase. Most of these gasworks continued to produce gas by directly-fired ovens as in Cordoba, Malaga, Murcia, Premià de Mar, Sant Feliu de Guíxols, Terrassa, Tortosa, Valls, Vilanova, etc. However, there were some gasworks that owing to the high consumption took advantage of the need for retort replacement by implementing more advanced systems that were more cost effective. This was the case of Cadiz and Barcelona. In Cadiz, Klönne installed a new factory with ovens of eight retorts in 1885. In Barcelona, some ovens of inclined retorts of the Coze system were implemented in 1890, for the fist time in Spain, at the gasworks in Barceloneta, which increased production and reduced labour costs.

The fierce competition between gas and electricity led to technological change in the gas industry. Some gasworks built recuperative ovens. This was the case of Mahon, Reus, Sant Feliu de Guíxols and Vilafranca del Penedès.

The largest factories, most of which were owned by the Compagnie Centrale d'Eclairage pour le Gaz Lebon, opted for Lachomette ovens, which were more suited to large gasworks. However, French technology implemented by the Compagnie Lebon was not adopted by Catalana de Gas, which preferred Bueb type vertical retort ovens from the German company Didier. In San Sebastian, where the company had belonged to the City Council since 1893, the Otto ovens, which were based on coke ovens, were preferred.

Reliance on foreign technology did not seem to be the best solution for small gas plants. One example is the gasworks at Valls. In this town, there was a directly-fired oven of 6 retorts. In 1911, Pablo Yvern, son of the owner, incorporated a gas producer and a recuperator designed and patented by himself. This new system had important repercussions for other small factories in Spain. Pablo Yvern Ballester (1879-1950?) had studied Industrial Engineering at the School of Barcelona. In 1901, he went to England to work as an apprentice at the Gas Light & Coke Company of London and to attend some classes for engineers. On his return to Spain, as manager of his factories, Pablo Yvern took out a patent on "Improvements of the heat recuperative ovens heated by gas". He installed his recuperative ovens at the factory in Valls and subsequently at other gasworks on the Mediterranean coast.

In 1938, during the Civil War, the Unified Gas Service of Catalonia (SGUC) made an inventory of gasworks in Catalonia. There were 25 gasworks of which only one, the one in Tortosa, was closed. Of these, there were only 8 that had directly-fired ovens. Twelve gasworks were equipped with recuperative ovens, 8 of which were of the Yvern type while the others used foreign technologies. This bears testimony to the significance of the Yvern recuperative. Lachomette ovens continued to be used at the Lebon factories although the factories of Gràcia, Arenal and Sant Martí had been taken over by Catalana de Gas in 1923. Nevertheless, the technical innovations introduced in these period concerned ovens of continuous carbonization. In Valencia after WWI the facilities were replaced by 5 Woodall-Duckham ovens, which used coal from Asturias. This technology was not restricted to large gasworks as shown by the factory in Reus.

After the Civil War, the ovens of continuous carbonization did not live up to expectations. The West Glover ovens in Reus did not work as expected. More noteworthy was the case of Barcelona, where these continuous ovens had never worked as continuous ovens but always as intermittent ovens. Consequently, in 1942, the Dr. Otto & Co. agreed to replace them, without charge, by other ovens of 5 chambers of intermittent carbonization. However, they were not implemented until 1947 because of WWII. The gasworks in Madrid used Koppers ovens, which were less common in Spain. These ovens were of intermittent carbonization and consisted of horizontal chambers. Some companies opted for less common ovens such as the Parsy oven, which was adopted in Calella, Girona and Vigo or the Hovine oven, which was installed in Jerez de la Frontera. There were few changes in technology between 1943 and 1960. In Granada Lachomette ovens were replaced by Collin ovens.

In the early decades of the 20th century, water gas was developed to be mixed with coal gas. Spanish public opinion in 1874 was not favourable to water gas given the controversy and restrictive decrees in England and France. However, this unfavourable opinion changed at the beginning of the 20th century. In 1902, in Gijón (in northern Spain) it produced water gas in a Dellwitch Fleischer gas producer to mix water gas and 30% coal gas for lighting. In 1908 a Kramers and Aats water gas producer were working in a factory in Cádiz. Nevertheless, the production of water gas took off in Spain in the 1930s and the Dellwitch Fleischer gas producer was the preferred model. This model was implemented at the El Arenal gasworks in Barcelona and subsequently in Sabadell. The Humphrey and Glasgow model was installed in Madrid, while the Kramers and Aats producer was adopted in Malaga. An Otto-Pintsch carburetted water gas producer was installed at the gasworks in Barceloneta in 1934 to complement the Dr. Otto ovens.

The Tully Gas Plant system was adopted in Córdoba in 1920 to produce gas using anthracite. This system, which was known as total gasification, was nothing more than a system that produced carburetted water gas. It was therefore installed at the factory in Reus in 1947 and subsequently in 1960 at the gasworks in Palma de Mallorca and A Coruña. From 1960 until the introduction of natural gas, the water gas producer became the most utilized method to obtain the town gas.

Conclusion

The gasworks in Spain bear testimony to the adoption of foreign technologies and also to the improvements made to these technologies.

In the early period, the most utilized technology consisted of directly-fired ovens of 3 or 5 horizontal ceramic retorts. However, at small gasworks, gas was obtained from fatty substances, mineral oils or hydrocarbons. Humbert gas and the rich gas were examples of this technology.

In the period of expansion, the specific process implemented in small towns continued to be developed by local technicians. This was the case of Arbós gas. Nevertheless, more advanced technologies, e.g. Klönne and Coze were imported to replace ovens whose retorts had deteriorated.

In the period of awareness of the need for technological change, efficiency was increased by the implementation of recuperative ovens. Small gasworks were equipped with recuperative ovens such as the Yvern recuperative, which bears witness to the development of local technology. Large gasworks were supplied with Lachomette ovens built by the Lebon Gas Company. The largest gas plants opted for ovens of vertical retorts.

The technological change was consolidated in the fourth period (1921-1938), during which recuperative ovens, such as the Yvern, began to be implemented in place of directly-fired ovens. Technological innovations arose from the introduction of continuous carbonization at large or medium sized gasworks.

Finally, the period of autarchy (1939-1960) confirmed the failure of the continuous carbonization method. In its place, the vertical retorts with intermittent carbonization were utilized. Other less diffused systems such as Percy and Collin were also introduced. During the first decade of the 20th century, some procedures to obtain water gas were implemented. The must notable example of this was the Tully Gas Plant in Cordoba. Nevertheless, the Otto-Pinstsch water gas producer was the one utilized in Barcelona after 1934 until the introduction of natural gas.

THE GAS MUSEUM

Maria MARÍN i GELABERT
Coordinator of the Gas Museum, Gas Natural Fenosa Foundation, SPAIN
mmaringe@gasnatural.com

Abstract

1992 saw the founding of the Gas Natural Foundation. One of its current lines of action is the sponsoring of cultural activities that help to preserve and disseminate the historical heritage of the gas sector. Through its Gas History Centre, it maintains, classifies and catalogues the company's Historical Archive. Comprising 53 funds and 3 collections, the archive occupies nearly three linear metres and has almost 68,000 individual records, 11,248 of which belong to its photographic collection. One of the aims of the Gas History Centre is to encourage original research and educational projects that will recover the historical elements of the sector. How the gas industry grew, its involvement in civic life, and technological advances in Spain, with particular emphasis on the people and places that have played a part in creating the world we live in today.

In 2006, Gas Natural's Board of Directors and the Foundation's Sponsorship Board agreed to set up the Museum of Gas project. This museum will bring together the Historical Archive and the company's collection of historical pieces containing over 3000 objects, and will work in tandem with the Gas History Centre. Its permanent and temporary exhibition rooms will display the history of gas with a brief overview of electricity, extending to the hybridisation of natural gas with new energies, and future developments. The complex will also house the Foundation's central offices and services.

The Gas Natural Fenosa Foundation is building the **Museu del Gas** in a 19th century listed building, where electricity was produced from gas engines, situated in the Plaça del Gas right in the centre of the city of Sabadell.

The architect who designed the building in 1899 was Juli Batllevell i Arús, a modernist architect very close to Gaudi, and the businessman who commissioned the project from him, was Joan Brujas, proprietor of "La Energia, S. en C.", a company which in 1913 became part of Catalana de Gas y Electricidad, S.A. the old name of Gas Natural Fenosa. Currently, the building is protected by the Sabadell Special Plan for Heritage Protection and the remodelling and part of the new construction, as well as the interior museum design, has been awarded to the Varis Arquitectes studio under the direction of the prestigious architect and museum designer, Dani Freixes.

A long-standing tradition

In 1977, the cultural curiosity of the company, in those days, Catalana de Gas y Electricidad, S.A., made it set up the first Permanent Exhibition on gas in its historical company headquarters at l'Avinguda Portal de l'Àngel 22, Barcelona. That first exhibition presented the historical evolution of gas energy and with the most advanced museum elements of its time showed the characteristics and applications of natural gas as a clean, efficient energy, one which respects the environment. In 2006, almost thirty years later, it closed due to the move of the headquarters of the company to Plaça del Gas, 1, to where the first gas factory in Spain had been.

In parallel, from 1987, they began to conserve and catalogue the voluminous Historical Archive, a testament, since 1843, to the activity and technology of the company, the pioneer in the Spanish market of the development of the gas and electricity industry. More discreetly, the company went on recovering interesting specimens of those antique domestic gas appliances (now known as gas domestics) which would be widely introduced at the end of the 19th and beginning of the 20th centuries.

In 2004, the Foundation assumed the management, conservation and diffusion of the historical heritage of the current Gas Natural Fenosa, creating the Historical Centre as an instrument to vitalise, investigate and spread the historical heritage of the company. The latest studies published are the books *La industria del Gas en Córdoba* (*The Gas Industry in Cordoba*) *(1870-2007)* and *La industria del gas en Galicia: del alumbrado por gas al siglo XXI: 1850-2005*, (*The Gas Industry in Galicia; from Street Lighting to the Gas of the 21st Century: 1850-2005*), a line which will continue with the coming edition of *La familia Gil: empresarios catalanes en la Europa del siglo XIX* (*The Gil Family: Catalan Entrepreneurs in 19th Century Europe*). To complete the challenge, the idea appeared of the Gas Museum project, a unique facility, which fortunately will be able to be inaugurated in 2011.

A corporate museum, but a museum of energy, technology and society too

The Museum's discourse will explain history and the future, energy and the environment, gas and electricity, milestones and persons, technology and society. In short, an extensive stroll along an interesting path which can be divided up according to the following guiding aspects of the museum project:

A space devoted to a corporate museum where the long history of the company will be explained, from the far off days of 1843, as the *Sociedad Catalana para el Alumbrado por Gas* (*The Catalan Gas Lighting Company*) (1843-1912), afterwards *Catalana de Gas y Electricidad* (1912-1987), *Catalana de Gas* (1987-1992) *Gas Natural* (1992-2010), right up to the current *Gas Natural Fenosa*.

A second space will describe the manufacture of gas and electricity in the 19th and 20th centuries, the technologies employed, the occurrence of social and historical changes, without forgetting the evolution of customs and habits brought in by the new inventions and ways of life.

The Museum wants to explain the past, but also to provide tools to act in the present which help to create a good future. The third museum exhibition space will talk about the energies of the future, about the importance of concentrating our efforts to create energy which is continuously available, economical and which has low level of environmental impact.

The top of the building has also wanted to be part of the museum and it will be available for visits. From it you can enjoy an urban view transporting you to the industrial and textile past of the city, but also enjoy the garden and pond fed by the water collected by the tank hidden under the roof tiles.

The temporary exhibition space will be inaugurated with the exhibition, *Juli Batllevell, un gaudinià oblidat* (*Juli Batllevell, a Forgotten Gaudian*), on the life and work of this important modernist architect.

Finally, the building will also be the institutional headquarters and offices of the Gas Natural Fenosa Foundation.

Fig. 1: Virtual image of the Gas Museum.

Preserving the company's Historic Archive

A unique element, which enables value to be added to the project, is the availability of a large Historical Archive which enriches the discourse and the pedagogical and research possibilities related to the Museum. It influences the design and the interior distribution of the spaces, but at the same time ensures the adequate conservation of the documents and images of the activity of Gas Natural Fenosa and of the companies which have made it up through the course of more than 160 years.

Fig. 2: An illustration by Alexandre de Riquer.

A sustainable building

The Museum wants to be an example of a sustainable building. In the rehabilitation and construction, as well as in the initial demolition of the unlisted parts, sustainable criteria have been applied, based on the reduction of the energy requirements, the generation of energy both efficiently and from renewable sources, the efficient use of water, the use of low environmental impact materials and the minimising of waste production.

A dynamic centre, for its immediate surroundings but also at a wide range

The Gas Museum aims to be a dynamic centre, devoted to energy in the interface with the environment and society. We are putting together an agenda of activities where the didactic and cultural offer will reach a wide range of public.

The Gas Natural Fenosa company operates in 23 countries. The Gas Museum website will be a virtual window onto the Museum which will enable the contents, the temporary exhibitions, conferences, workshops and seminars taking place to be at the reach of everyone. It also aims to be a way to accede to the document archive and the collection.

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 668.

THE PRODUCTION AND CONSUMPTION OF GAS IN MÁLAGA (1854-2009)

Mercedes FERNÁNDEZ-PARADAS
Universidad de Málaga, SPAIN
paradas@uma.es

Abstract

The present work studies the evolution undergone in the production and consumption of gas in Málaga from 1854 –the year of the inauguration of public lighting– to the present day. To this end I have brought together the relevant statistics and information analysis, relating it to those factors which have conditioned the development of this activity, namely: the technology used, the business aspect, the spread of electricity and butane gas, the socio-economic structure of the city and the size of its population. The case of Málaga is particularly interesting due to the fact that it was, and still is, one of the largest urban areas in Spain –81.000 inhabitants in 1860 and 566.000 at present day– in addition, it underwent a notable industrialisation process from the mid-eighteen-eighties to the nineteen-twenties.

Introduction

The present work examines the evolution undergone in the production and consumption of gas in Málaga from 1854 –the year of the inauguration of public lighting– to the present day.

I have drawn up a series of statistics reflecting the production and consumption of gas. Information that I analyze in relation to some of the factors that determined its development: the technology employed, the business management, the extension of electricity and butane gas, the socioeconomic structure and the number of inhabitants.

In Spain, Málaga was among the first cities to have gas. Different factors explain this early start. It was and still is one of the largest cities in Spain –79.000 inhabitants in 1854 and 566.000 today. It underwent a remarkable industrialization process. These factors included its port facilities, and the future construction of railways, which would make coal supplies easier.

The case of Málaga is interesting because it was one of the most industrialized cities from the 1830s to the 1920s. It was due to the benefits from the profitable overseas trade especially based on the export of agricultural products in the last third of the 18th century. This benefitted an important number of industries, especially some of the main textile and iron and steel industries of the country such as Manuel Heredia's foundry. One of his factories was set up in 1833 in Málaga, and the textile industry *Industria Malagueña* in 1846. We can also point to other industries such as the production of containers, chemicals (sulphuric acid…), and agricultural industries (wine, liquor and raisins)[1].

In the history of gas in Málaga, there are three cycles to highlight, depending on the energy employed: 1st. 1854-1968 was the period of the production of gas from coal; 2nd. 1969-1992 the period of the production of gas from oil; and 3rd. 1993-2009, the period of natural gas.

Gas made from coal (1854-1968)

Gas was first used, in 1846, by one of Málaga's most important industries, the *Industria Malagueña*, for its own-consumption. The manufacture for the sale of gas began in 1854.

In 1848 the *Empresa General de Alumbrado de Gas* began to build a gas factory. The *Empresa General de Alumbrado de Gas*, which was founded in 1846 when the English entrepreneurs, Manby and Partington, set up the *Sociedad Madrileña para el Alumbrado de Gas*. This company created *Empresa General Peninsular de Alumbrado por Gas* in the same year, planning to extend its activity to diverse places in Spain, like Valencia, Cádiz, Santander and Málaga between 1846 and 1848. However, it was not possible because of the difficulties that arose from the problems connected with coal supply, the diversity of the activity, and the changes in the economic system. Consequently, the construction of the gas factory in Málaga was never completed.

In 1852, the manager of the *Empresa General de Alumbrado de Gas* Luis Gosse obtained the monopoly of public and private lighting supply in Málaga. It was Gosse, who began the production for the sale of gas in Málaga, first used for public street lighting, in 1854. In the same year the business was taken over by the French group Vautier, which later formed la *Societé pour l' Eclairage de Malaga*, in 1859.

The factory was built on the outskirts of Málaga, in the area of Arroyo del Cuarto, where many other industries were located. This place was suitable because it was near the port and the future railway station of *Ferrocarriles Andaluces*, so, it would make the transport of coal and its waste products easier[2].

As for the city of Málaga, it is worth pointing out its early role as a centre of commerce, which laid the bases for its early industrialization, which began in the 1830s. It was this early industrialization that made the city attractive to the gas company. However, the larger factories chose the production of gas for their own use, and when electricity appeared they changed to this new form of energy, leaving gas behind. In addition, the level of income for most of the population was low, which meant their expenditure on gas was minimal, because it was considered a luxury product. Other problems the company faced were the distance from the coal sources and the expense of transporting coal from the mines of Cordoba.

We can see in Figure 1 that in each historical cycle, there are various stages, conditioned by their endogenous and exogenous factors mentioned above. Thus, between 1880 and 1968 there are the following periods when production fell: 1880-1895; from the first World War to 1921, the latter period subject to sharp rises and falls in production and finishing in a pronounced slump; the 1930s; and from 1951 to 1968. The periods of growth were: the first years of the twentieth century up to the First World War; the Dictatorship of Primo de Rivera (1923-1929); and from 1943 to 1950.

It was a complex process, in which strategy was decisive, especially when faced by challenges. As for example, when during the 1880s and the early nineties of the 19th Century, highly-qualified staff were contracted, the factory was modernized to compete with electricity, sales to private concerns increased, and there was an improvement and the extension of lighting to other zones[3].

Although the period 1900 to 1913 was one of growth, the increase in electricity production was even higher. The two most important electrical companies, the German *Siemens Elektristche Deutsche* and the English *The Malaga Electricity*, increased their production significantly and from 1903 they bought what was necessary from *Hidroeléctrica del Chorro*. In 1913, *Siemens* and *The Malaga Electricity* were the leaders in the lighting business[4].

Source: Table 1.

The reaction of *Lionesa* was changes to its gas machinery in order to face competition from the electrical companies. In 1912, the gasworks was remodeled. *La Lionesa* bought 6 "Lachomette" furnaces with 54 vertical retorts and other technology that could keep the furnaces hot[5].

In the first years of the 1920s, the prospects of the *Lionesa* were not good, because it had lost its old share in the lighting business. However, in 1923 a new company, *Sociedad General de Aguas de Barcelona,* took control of the *Lionesa* in a period of economic and demographic boom[6], which helped to change the situation in the gas business. From 1923 to 1929, the *Sociedad General de Aguas de Barcelona* made decisive changes to the business, at just the right moment.

The investments of 1924 in the gas system and factories made the service more efficient and helped to increase the number of customers that used gas in their own house for cooking and lighting[7]. They also supplied some factories that had been self-sufficient up to then. According to Arroyo, all this was possible thanks to a business policy of taking on short term and long term risks. The importance that private consumption was acquiring, representing 70% of the income in 1929, helped to strengthen the sales system. Also, the street lighting was extended to new urbanized areas[8].

Sociedad General de Aguas de Barcelona sold *Sociedad para el Alumbrado de Málaga* to its branch *Compañía Española de Electricidad y Gas Lebon*, acquired in 1925. Thus, *Alumbrado de Gas* became a branch of this latter[9].

Regarding the stage from 1951 to 1968, we can see in Figure 1 that it was a period characterized by a crisis: gas production and the number of consumers decreased sharply[10]. In the 1950s, the gas produced by coal couldn't compete, due

[10] In Málaga, during the period 1951-1968, the consumption by household customers and industry stayed the same, with a slight decrease in the former. From 1952, the number of customers in the city of Barcelona grew. SINDICATO NACIONAL DE AGUA, GAS Y ELECTRICIDAD: (1958) *Estadística comparativa de la industria del gas. Año 1957*, Madrid; (1960a) *Datos estadísticos técnicos de las fábricas de gas españolas. 1950-1955*, Madrid; (1960b) *Estadística comparativa de la industria del gas en España durante los años 1957, 1958 y 1959*, Madrid; *Datos estadísticos técnicos de la industria del gas*, Years 1961-1968, Madrid. ARROYO, Mercedes

to its new competitors –liquefied petroleum gases such as butane and propane gas–; low tariffs charged; the huge number of workers; and the anachronistic infrastructure. All these factors influenced the decline of the business.

The introduction of butane and propane gas represented very strong competitors for coal-based gas and it was the main reason for its decline. In 1953, Spanish refineries began to sell butane and propane gas, and in 1957 the company *BUTANO* was founded. This company's aim was to take advantage of the cuts in electricity supply, which reappeared in 1956-1957[11]. Butane gas was well-received by the population and industry because: it was cheap, it was efficient and easily transported.

In Málaga *Electricidad y Gas Lebon* decided to eliminate coal-based gas. First Málaga used oil as a raw material. At the beginning of the 1960s, it tried to produce gas through a thermic cracking process using light naphtha but it was unsuccessful.

Once again, the gas industry reacted to the new challenge, by finding new systems of production based on oil. It was the company *Catalana de Gas y Electricidad*, now *Gas Natural,* which reorganized the gas industry. As from 1965, this company controlled the *Compañía Española de Gas.*, which was the owner of gasworks in Cádiz and Málaga. In 1968, in Málaga, *Gas Natural, S.A.* set up two Cifuindus plants that used light naphthas in the catalytic cracking process[12]. In Spain, *Catalana de Gas y Electricidad* was the first gas company that had this type of plant in 1956.

Gas made from oil (1969-1993)

Gas manufactured from oil continued until 1993, its main characteristic being a marked increase in production between 1969 and 1977. As we can see in Figure 2, gas production doubled between 1969 and 1977. This coincided with a period of economic expansion in Málaga[13].

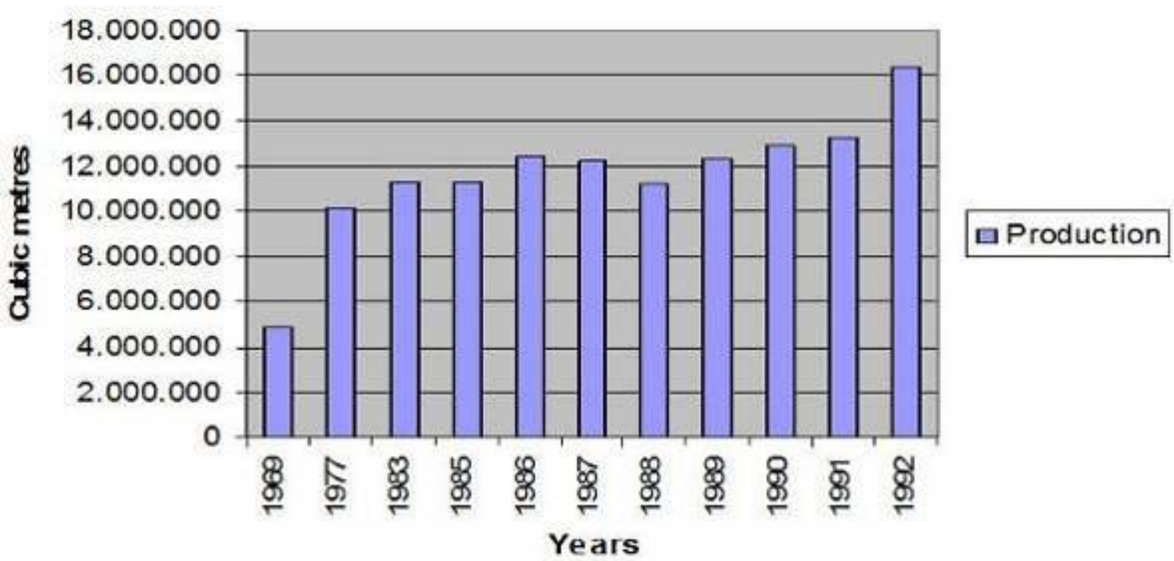

Fig. 2: The production of gas made from oil in Málaga (1969-1992)
Source: Table 1.

The transition to natural gas began in 1992. The previous step was the building of a propane gas plant. It was essential to replace the petroleum gas by natural gas. A process started in Spain in 1969, which came to Andalusia three

(2006b) "Los cambios en el proceso de producción y de distribución de gas en Barcelona y su *hinterland* (1930-1961). Entre el gas de hulla y el gas natural", *Sripta Nova*, núm. 218.

[11] FÁBREGAS (2003), 154-159. SÁNCHEZ GUTIÉRREZ, María Matilde (2006) *La regulación del sector del gas natural*, Valencia, Tirant lo Blanch, 64.

[12] FALGUERAS, Francisco *Una industria centenaria,* Catalana de Gas y Electricidad. GARCIA DE LA FUENTE (1984).

[13] PAREJO (2009), 287.

decades later, specifically in Seville, where the replacement process finished in 1991, carried out by *Gas Andalucía*. In 1987 *Gas Andalucía* was founded. In 1995, *Catalana de Gas*, now *Gas Natural,* became the only shareholder of *Gas Andalucía*[14].

In 1993, the establishment of plants in Málaga and Cádiz, where liquefied natural gas was brought and regasified, put an end to naphtha as a raw material in Andalusia[15].

Natural gas (1994-2009)

We can see that the gas consumption has increased greatly (Figure 3). Between 1994 and 1996 the consumption of manufactured gas was around 13-14 million cubic metres –m^3–, while the consumption of natural gas only represented 1 million m^3.[16] But since 1997, the situation has changed because only natural gas was supplied (73 million m^3 in that year). It was from 2001 that consumption increased in a spectacular way, coinciding with the spread of the new gas system to other different municipalities: the main coastal towns like Fuengirola, Mijas… and also those in the interior such as Ronda and Antequera…

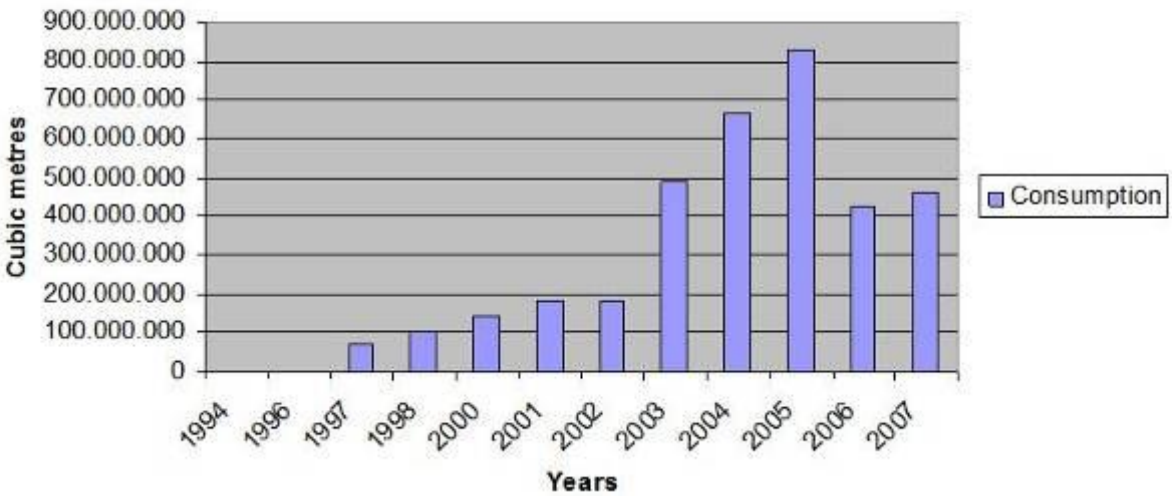

Fig. 3: The consumption of natural gas in Málaga (1994-2007)
Source: Table 1.

Between the years 2001 and 2007, the increase in consumption was really important, reaching, in 2005, the highest figure, 827 million m^3, an increase caused by the rise of the income levels and the building business. This spectacular rise was related to the increase of incomes of the working population and also with the boom in the construction industry. It is a market of more than a million people, exceeding 70% of the population of the province. At present, Cádiz and Huelva are the Andalusian provinces with the highest consumption levels, and Málaga is the 6th province in this context, at a distance from these two.

The increase in the consumption of gas has been possible thanks to important investments in transport and distribution networks, which have allowed its connection to the Iberian network. The natural gas network of *Gas Natural Andalucía* has grown considerably since 2001. It had 268 kilometres in that year and 802 kilometres in 2008. It represents 24% of the regional network, the second province after Seville[17].

The changes coincided with a moment of profound transformation in the sector, due to the liberalisation process started in 1996. From the 1st of January 2003 one could choose between the usual natural gas supplier and any of your choice. In that way there were two markets: a regulated one and one without restrictions[18]. In Málaga, in 2004, 75% of the

COMMON PATHWAYS USED FOR THE INTRODUCTION OF THE TECHNOLOGY OF GAS IN CATALAN CITIES DURING THE SECOND HALF OF THE NINETEENTH CENTURY. THE CASE OF REUS AND OTHER SIMILAR CITIES

Florentino MOYANO JIMÉNEZ
Universitat Rovira i Virgili, and Gas Natural, SPAIN
fmoyano@gasnatural.com

Abstract

The bourgeoisie of the Catalan town of Reus looked keenly all that happened in Barcelona, the most cosmopolitan and important city in Spain. At the same time, Barcelona looked to the northern cities in Europe, specially London and Paris, longing to be on its same level of modernity by gaining the last technologic innovations that could increase their quality of life.

About the gas industry, Barcelona created their first infrastructures three decades after London and two decades after Paris. As in Barcelona, the Reus bourgeoisie had the control of industry, trade and municipal government, and therefore they could decide on the future of the town. Ten years later, in 1854, the gas industry was installed in Reus. The Catalan bourgeoisie kept nexus between them, and created a channel for the technologic knowledge from developed countries.

This communication tries to establish these common channels for introducing the gas technology in the Catalan towns, and I take the case of Reus as an example because at that time it was the 2nd Catalan town in economic and demographic importance. At the beginning, technologic communications were conducted in England and France. England exported technology, technicians and soft coal. France only exported technology and technicians. But both countries also exported business initiatives. It was only a one-sense communication channel.

Introduction

This communication aims to establish the technological introduction process of the gas in smaller towns and reference cities like Reus and their environment.

In mid 1800s, the gas industry was introduced in Catalonia with British and French capital and technology.

The beginning of the gas industry in Spain was late. It became the second wave of the sector which reached peripheral Europe.

Reus was the second Catalan city in economic and demographic importance, at a hundred kilometres from Barcelona. Reus joined the gas industry in 1854. A year later, it went into modern European light.

The idea that Reus had to look like Barcelona came from the bourgeoisie. A decade earlier, the bourgeoisie from Barcelona had wanted to enjoy the technical advances of cities like London and Paris.

Actors and technological measures that established the Catalan gas industry.

1. Foreign technicians

Not a large number of foreign technicians acted in Catalonia, but they were the first to introduce the knowledge and tools required by the gas industry.

Foreign technicians came mainly from the British Isles, France and Germany.

William Richards built factories in Reus in 1854, and in Tarragona in 1858. The gas meters and other tools were imported from England. Some years before, Richards had been an engineer of the *Sociedad Catalana para el Alumbrado por Gas*, from Barcelona.

Richards is a clear exponent of the nexus between technicians and foreign technology.

2. Foreign companies

The British and French initiatives were established in Spain because the energy market was still virgin. The reason was to be able to vent their financial and technological interests.

The foreign gas company tried to generate orders from participating companies. Thus, these companies could provide an outlet for the production of elements for the gas industry.

Other foreign firms, with a smaller presence in the country, tried to settle in Catalan cities such as Girona, Tarragona and Valls. These companies wanted to settle in this type of medium-sized cities because they fitted their potential business.

The creation of new gas companies generated an open path for technology transfer. The most active representative of this process in Spain was Charles Lebon.

3. Foreign Consulates in Catalan and Spanish cities

This institution protected the interests of the subjects of their respective states.

As an example, we find the relationship between William Richards and Tarragona's British Vice Consul, Edward Bridgman. Vice Consul in 1857, he recommended an English engineer to the City Council.

Richards got the concession to settle the gas lighting in Tarragona. Bridgman became the Manager of Richards' firm, the *Sociedad Tarraconense para el Alumbrado por Gas*.

The relationship between Bridgman and Richards continued in collaborating in the manufacture of gas meters. The application of the invention privileges is an evidence of the economic relationship between them.

In other Spanish cities, as in Ferrol, there were similar cases.

4. Speculation and the added value of gas factories

Existing companies were dedicated to build gas factories to sell them right away and get immediate profits.

Selling gas factories infrastructure was the most conservative economic method in gas industry. William Richards practiced this method of making money. He built factories, in addition to Reus and Tarragona, in Sabadell (1851-1852) and Manresa (1858).

Long term exploitation of the gas enterprise had the risk of benefits irregularity. The economic success of the company depended on fluctuation in coal prices and on demand growth.

Speculation in the construction of gas plants had a positive technological aspect: in each new factory, new technical improvements were applied that appeared within the sector.

5. The profit reason

The profit reason is the primary goal for any capitalist economy. In the case of Catalan gas corporations, there was a target for all shareholders.

This business expectancy acted as an incentive for technological innovation. When you got big profits, research on new applications were accelerated.

The benefits of the Reus company, *Gas Reusense*, were considered as excellent since 1860. The development of the gas company allowed an improvement of production and, in 1898, led to access to the electricity business.

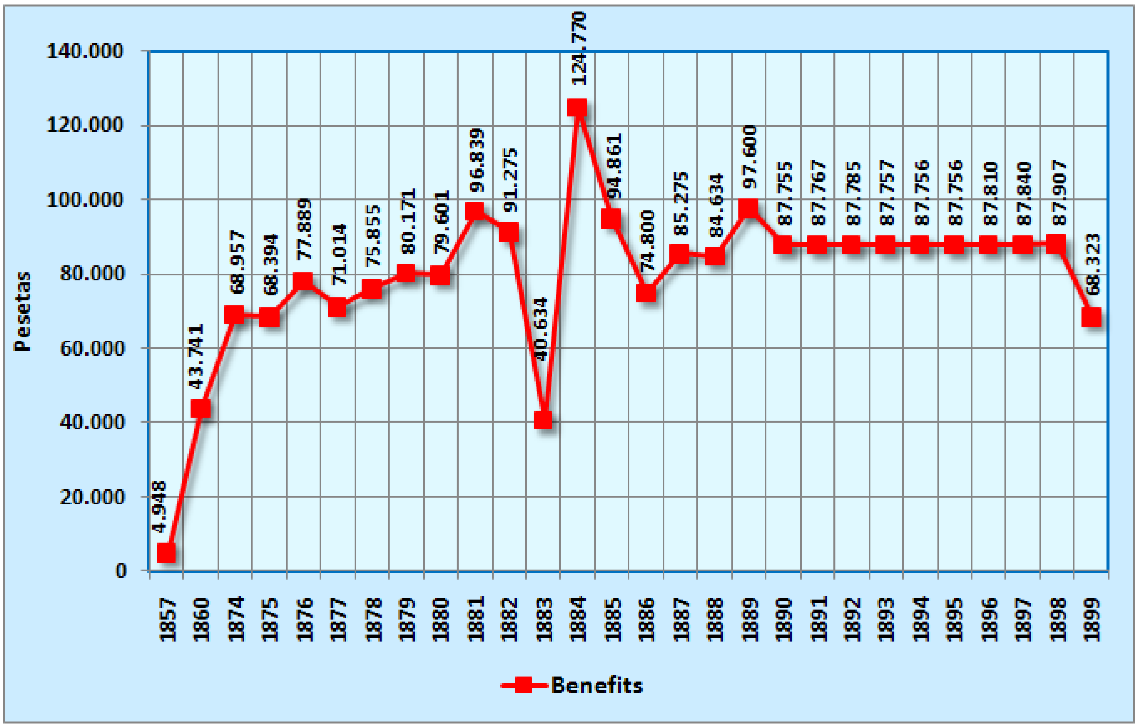

Fig. 1: *Gas Reusense*'s benefits in the period 1857-1899.

6. The Spanish government performance: patents and privileges for invention

In the year 1826, a Royal Decree was established on the patent. This new legislation introduced more categorical rules about invention and introduction of patents.

Despite the protectionist policy of the Spanish State, the gas sector employed foreign capital and patents. This external dependence was due to the lack of its own technological base and to an inability to invest in major industries.

In the Spanish gas industry the kidnapping of foreign patents was usual. The limited capacity for invention and patent creation drove companies to try to improve the copied object. This form of copy served also as a way of technological penetration.

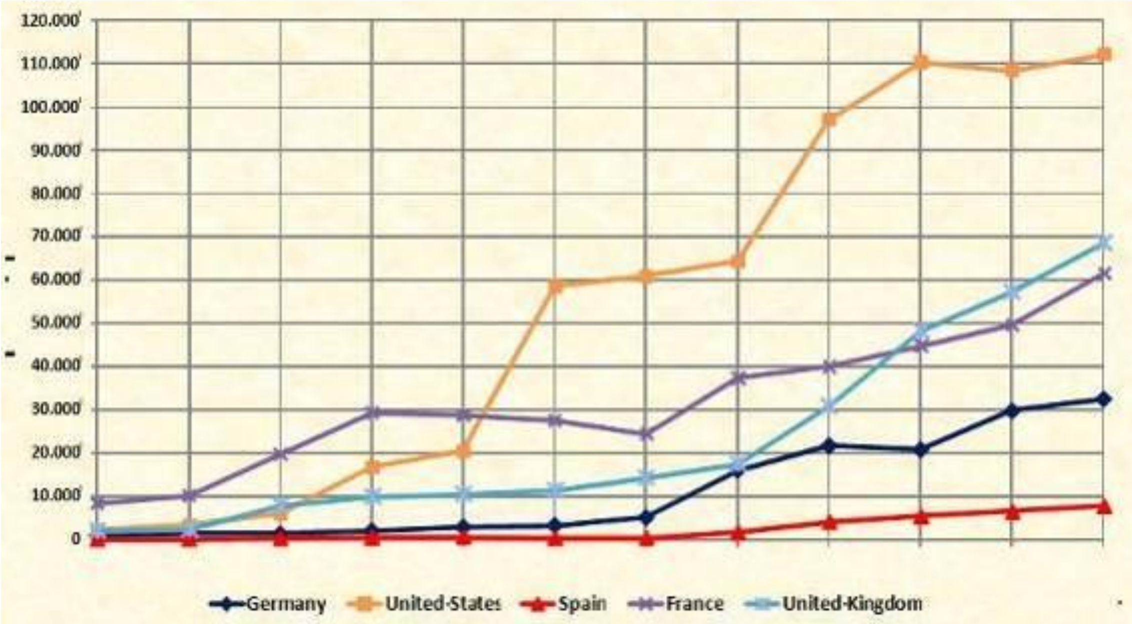

Fig. 2: International Patent Statistics, 1841-1900.

Table 1: Distribution of patent applications as economic activities in Spain, 1851-July 1878.

Economic activity	Patents	% of total period
Capital goods	568	13,4
Textile	539	12,7
Processing of primary products	490	11,6
Services	367	8,7

	Electricity production.	5	2,54
	Electric lighting.	6	3,05
	TOTAL ELECTRICITY	**21**	**10,66**
TOTAL SECTORS		**197**	**100**

7. City councils

In the case of the cities of Reus and Tarragona, the city councils acted as promoters of companies introducing gas lighting.

They opened an important path for the entrance of technological gas industry and encouraged local capitalists' proposals.

If private elements were essential in the industrial establishment, no less important was the interest shown by local public entities.

The municipalities imposed in the contracts with concessionaire's enterprise the Advancement of Science Clauses. These provisions contributed to technological innovation. Reus explicitly stipulated for the mixed lighting of the city by contract, achieved in 1897.

They also encouraged the industry access to technology by promoting their participation in various international exhibitions held during the nineteenth century.

8. The performance of Catalan industrialists and capitalists

They made trips during the first decades of the nineteenth centuryto the technological heart of the moment, sometimes to buy tooling for the textile industry.

Experiences outside the Catalan bourgeoisie were transmitted within the group itself. In this way, technology was transferred between members of different cities.

The contact between the bourgeoisie of various cities is evidenced by the fact that the shareholders of *Gas Reusense* resided in Barcelona. Macià Vila, a major industrial of the city of Reus, represented the interests of these shareholders.

9. Connections of the bourgeoisie with the country's politicians

General Prim, Pascual Madoz and the Earl of Retamoso, prominent politicians of the age, were part of the shareholding of the company *Fabril Algodonora*, which was ran by Macià Vila.

The friendly relationship between General Prim, a military and progressive politician who became President of the Council of Ministers of Spain, and Macià Vila established a personal affinity.

The correspondence between Macià Vila and General Prim mixed personal issues with economic and political interests of them both. It is a clear example of the complicity between politics and economics in the nineteenth century.

Exchanges between industrialists and politicians were necessary and constant. Politicians required industrial capital to finance their political positions to remain in power. In return, industrialists received valuable information and favourable treatment.

10. The School of Chemistry of the **Junta de Comercio** *and the Industrial Engineering School of Barcelona*

The bourgeoisie emphasized his interest in the country industrial education and the maintenance of free schools of the *Junta de Comercio de Barcelona*. This institution covered the costs of its pensioners studying the natural sciences and industrial arts abroad.

In Spain, the industrial studios were founded in 1850. In 1851 the Industrial School of Barcelona was created, which brought schools and Chairs from the *Junta de Comercio*.

The School of Engineering of Barcelona was the only one responsible for providing Catalonia with the senior technicians that the country industrialization required during the second half of the nineteenth century.

In Reus, the technical direction of the gas factory was changed in 1859. Engineer Richards, who ran the factory, passed all responsibility to a local technician, Josep Simó Amat.

In the 1880s, the School of Industrial Engineering was socially recognized, but since the 60s, these Catalan engineers already controlled some gas plants in Catalonia.

By the end of the century, as seen in the town of Reus, the figure of Industrial Engineering was established both in private companies and public institutions.

11. The **Fomento del Trabajo Nacional** *and the Chambers of Commerce and Industry*

The *Fomento del Trabajo Nacional* was the result of employer associations developed during the nineteenth century, and represented another channel of technology penetration.

The *Fomento* spread technological and economic developments inside and outside the country by publishing their magazine. Also through the celebration of meetings such as those held in Reus and Manresa in 1894.

Among the tasks performed by *Fomento*, some highlights are its involvement with some economical corporations, new technologies and improvements in the gas industry.

Fomento and, later, the Chamber of Commerce, created a kind of industrial education to spread other nations' industrial developments.

Since 1900, the Chambers of Commerce, Agriculture and Industry agreed to become partners of *Fomento*.

The existence of contact between the Catalan gas companies and private institutions was obvious. A good example is the relationship between *Fomento* and the Reus gas company, which exchanged technological knowledge and economical aspects.

12. The **Sociedad Catalana para el Alumbrado por Gas***, of Barcelona*

This company was the mirror in which all other gas companies tried to reflect, especially in Catalonia.

The abroad contacts of *La Catalana* were a way of introducing important technology to the rest of companies.

The relationship of *La Catalana* with foreign technology was initiated at the moment of its creation due to the figure of its shareholder Charles Lebon and the technological elements he imported from others countries.

Through the *Centro Científico Industrial* of Barcelona, *La Catalana* came to know of foreign innovations and prestigious French journals as *The Célébrité* and the *Journal de l'Eclairage au Gaz*.

The participation of shareholders of *La Catalana* in the *Gas Reusense* company created an important link. The correspondence between the two companies on technological and economic items was usual.

The bibliography of *La Catalana* about gas industry consisted on about 40 volumes acquired between 1845 and 1900. This collection became a place of reference for technical consulting.

13. Reus' economic and cultural associations

The *Sociedad de Amigos*, formed by Reus capitalists and industrialists, was born in 1839. This society was the predecessor of *El Círculo*, created by the most important taxpayer of the city in 1852.

Members of *El Círculo* owned most of the means of production and political control of the city. It was a vital centre of business and technology. Some of their members were shareholders of *Gas Reusense*.

There were other economic and cultural associations in Reus, such as the *Centro de Lectura* created in 1859 and the Chamber of Commerce and Industry of Reus.

These institutions also provided innovative technological knowledge during the second half of the nineteenth century.

14. Local technologies and cultural publications

The publications that came out in Reus in the 19th century were another channel of technological knowledge.

One of the most prestigious cultural magazines of the city was the *Eco del Centro de Lectura*. Published by the *Centro de Lectura*, it included articles about gas and its applications.

At the *Centro de Lectura* library there were books about gas technological evolution. In the archive there are still copies of the *Revista Industrial*, from the period between 1861 and 1863, which published all technical innovations –among other disciplines, the gas industry.

***15. Bibliography and subscriptions to foreign journals used by* Gas Reusense**

The bibliography on gas industry appeared intensely from the moment it became an energy sector. But it increased its volume with the onset of electricity. It made the access to foreign technological books easier.

The first books and magazines that Catalan and Spanish gas companies acquired were, basically, French and British. *Gas Reusense* was no exception.

The books found in Reus and Tarragona gas companies were edited in Paris and Liege.

Gas Reusense sought its own channel to gas technology by subscribing to the most important publications published abroad: the French *Journal de l'Eclairage du Gaz* and the *Engineer* and the *Journal of Gas Lighting*, both published in England.

Another path used by *Gas Reusense* to join technology in a safe and efficient way was to become a member of the Gas Manufacturers Association.

16. Catalan technicians take responsibility

The first Catalan and Spanish gasworks were created and driven by foreign engineers, but they were quickly replaced by local technicians.

Since 1860, an important technological assimilation was initiated, and knowledge achieved by local engineers could be considered as sufficient.

In 1880, the gasworks were built by engineer I. Boixaderas in Valls, and it was governed and administered by engineer J. Borras, who were both students of the School of Engineering of Barcelona.

According to the *Anuario de la Minería, Metalurgia y Electricidad*, in Spain in 1900 the gas factories management were directed by more Spanish engineers than foreigners, in a ratio of 9 to 4. The *Anuario* of 1905 established that the ratio of engineers working in Spanish gas industry were 10 to 1.

Conclusions

Cities became the stage for the nineteenth century economic development. A new energy appeared on them for public lighting: gas.

The gas industry in Barcelona (1842), Reus (1854) and Tarragona (1858) needed pathways for technology introduction, and to consolidate itself it also required a number of actors to perform a set of technology activities.

The birth of gas industry in Catalonia and Spain had a foreign origin. The foreign experts introduced the materials and the knowledge that the industry needed.

The source of technical and foreign gas companies were mainly the British Isles and France.

William Richards built factories in Reus and Tarragona with British materials, and he created his own company in the Catalan energy market, that was practically virgin.

In most Catalan cities, the main actors that made gas industry possible were the councils, which acted as promoters, and local industrialists and capitalists, who invested to achieve it.

Macià Vila was the industrial prototype that worked for mutual benefit taking profit from his country's political connections.

Some private institutions collaborated, too, in the introduction of technological innovations in Catalonia. We highlight the *Fomento del Trabajo Nacional* and the Chambers of Commerce.

The reference company for the Catalan gas industry was the *Sociedad Catalana para el Alumbrado por Gas*, of Barcelona. *Gas Reusense* and *La Catalana* maintained contact since the beginning of the activity of the Reus Company. The fact of having some common shareholders was a big help.

Bibliography and foreign magazines were another way for the transmission of knowledge to Catalan cities.

The new techniques required a transmission and consolidation of knowledge, which could only be done in a systematic way at technical schools and universities.

Since 1880, industrial engineers were socially recognized, but before that, as in the case of Reus, the technology transfer process from foreign technicians to local ones had already begun.

The process of technology assimilation in the gas industry could be considered as consolidated in late nineteenth century, when most technicians in industrial factories had already been educated at industrial schools of Barcelona and Madrid.

BETWEEN ASTROPHYSICS AND GEOPHYSICS: THE FRENCH CONTRIBUTIONS TO THE STUDY OF AURORAS AT THE BEGINNING OF THE 20TH CENTURY

Stéphane LE GARS
Centre François Viète, Nantes, FRANCE
stephlegars@free.fr

Abstract

Atmospheric researches were initiated in France during the 1860s by the physician and astronomer Jules Janssen, who created for instance the expression "telluric lines" to name the terrestrial part of the solar spectrum. This work was continued at the Meudon Observatory at the end of the 19th century, where Henri Deslandres inferred knowledge of atmospheric phenomena by means of mimetic experiments on cathode rays in vacuum tubes.

We will examine how these atmospheric researches were pursued at the beginning of the 20th century. First, we will detail the work of Charles Nordmann, who tried to make a link between auroras and radio waves emitted from the sun, and experimented at the top of the Mont Blanc to detect those waves. Afterwards, we'll examine the way by which the "French school of molecular diffusion", initiated by Jean Cabannes, a Charles Fabry's student, paid attention to the auroras. In the end, we will focus on the researches of Alexandre Dauvillier in cosmic physics, and his participation in the French expedition of the Second International Polar Year (1932-1933) at the Scoresby Sund, during which he ruined the hertzian and ultraviolet theories of auroras, and confirmed the spectroscopic results of Vegard.

In this way, we will point out the place auroras took in atmospheric lights researches in France (auroras, light of the night, sky, zodiacal light, …), the articulation between field observations and laboratory practices, the collaboration between French and Nordic physicists, and we will question the ways and meanings by which atmosphere was at all once an astrophysical and geophysical object.

At the end of the 19th century, astrophysics and geophysics started to be identifiable and institutionally stabilized fields in France. Nevertheless, some objects were always ambiguous and didn't respect rigid boundaries. For instance, atmosphere was studied all at-once by physicists, astronomers or meteorologists and became a strategic place between heavens and earth. Atmospheric researches became in France a real stake and various styles of researches were observed in their study: atmosphere could be studied because of the possibility it offered to explore the interactions between light and matter; atmosphere became an object allowing analogies and technical transfers between the study of stars and the study of the earth; and atmosphere was also an important part of a new discipline, cosmic physics, seen as an interdisciplinary science making the coordination between astrophysics and geophysics.

In this context, auroras, seen as part of atmospheric researches, were largely studied by French scientists. Our paper aimed first to do a review of the French polar expeditions, during the 19th century and the beginning of the 20th century, where auroras were observed or analysed. The first of them was the 1833 expedition of Jules Poret de Blosseville, during which terrestrial magnetism was studied on the suggestion of François Arago. But auroras became systematically and largely studied during the 1838-1839 *La Recherche* expedition: Bravais tried, influenced by Arago as well, to detect connections between auroras and terrestrial magnetism. If scientific aims were aimed, it must be recognized that a specific political context will have to be explored further. Indeed, Arago and Humboldt had a cosmic thought that was not the same than the scientific and philosophic thought of Gauss and Weber in Germany. If Arago and Humboldt wanted to measure all the magnetic particularities at the surface of the earth, Gauss and Weber preferred an abstract mathematical approach where local singularities were not to be taken into account. This difference between these two methodologies stimulated English reflections about the way to explore the earth, and led to the "magnetic crusade"[1]. The *La Recherche* expedition will have, in this respect, to be studied in this scientific and political context. Indeed, Bravais, charged with the measurement of magnetic parameters and their relation with auroras, seems very ambiguous with the French position and more inclined to adopt the German method when he says:

> "En Allemagne, MM. Gauss et Weber, à la tête de l'association magnétique allemande, montraient par la publication annuelle de leurs *résultats* que l'on pouvait mesurer avec un grand degré d'exactitude les plus petites variations de la force magnétique.[…] Les belles observations de M. Arago sur l'influence lointaine exercée par les aurores boréales laissaient encore indécises la question des petites et incessantes déviations ; l'observateur ne leur attribuait qu'une faible importance, les considérait comme d'inexplicables anomalies et ne s'attachait qu'à comparer entre les moyennes déduites d'un grand nombre d'observations. Mais, en 1838, l'expérience de l'association magnétique allemande prouvait déjà que cette manière de voir n'était pas exacte, que les variations indiquées n'avaient point une origine purement locale, et que la cause inconnue qui leur donnait naissance étendait son action à des distances considérables : ainsi un intérêt tout nouveau devait désormais s'attacher à leur étude."[2]

Thereafter, the South Pole was more explored by French expedition than the North Pole. We can cite the *La Romanche* expedition in 1882-1883, during the first polar year where various scientific researches were made, concerning meteorology, magnetism and auroras, geology, botanic, zoology, hydrographic and oceanographic measures, anthropology, and, as well, the observation of the transit of Venus. In 1893-1894, Calloch de Kerillis, captain of the *Chasseloup-Laubat* stayed in Newfoundland where he particulary investigated the auroras: he imagined a heliodynamic theory of the auroras using as well the 1882-1883 results[3]. For him, the earth was surrounded with atmospheric and concentric rings, centred on the Gauss Pole, and constituted by an auroral matter, non luminous by itself, and put in an isostatic equilibrium under the influence of the terrestrial magnetism. The Earth would be like a comet, with a tail, where a "solar induction" provoked luminous phenomena.

But the most important expedition for the auroras researches was in no doubt the 1932-1933 expedition in Scorseby Sund prepared in the context of the 2nd Polar Year, during which Dauvillier carried out the first important study of this phenomenon. Instead of an electrical theory, Dauvillier used electrons –cathode rays, as named at the beginning of the 20th century– to build an electronic theory named "secondary electrons auroral theory". In his course of cosmic physics, in 1954, he can claim, on the basis of laboratory experiments, observations and measurements made during his polar travels, and on mathematical treatments, that secondary electrons are produced in the exosphere by solar corpuscles, and then excited by primary electrons that gravitate in the terrestrial field: those electrons then go down from this orbit and bombard the earth. For him, auroras are, consequently, a permanent phenomenon, that can be observed everywhere on the earth.[4]

Thereafter, expeditions occurred in 1934-1935 in Abisko, and in 1937-1938 in Trömso. In Abisko, Dauvillier was accompanied by the French scientists Daniel Barbier, Daniel Chalonge and Etienne Vassy: they made atmospheric researches concerning ozone and auroras. In Trömso, René Bernard, from the Institut de Physique Générale de l'Université de Lyon, made spectroscopic researches of the auroras and of the night sky light.

During this period, auroras stimulated theoretical questionings, above all after the discoveries of new radiations and new corpuscles at the end of the 19th century. For the physicist Charles Nordmann, auroras resulted of the light created in the terrestrial atmosphere because of the effects of hertzian waves emanated from the sun. In a communication made on November 20th,1903, Nordmann summarizes the various auroral theories to discuss and criticize them. For him, magnetism couldn't be invoked, because of the lack of magnetic perturbations frequently noticed during a great number of polar expeditions: in this way, it can be said that the observations made during the 19th century polar expeditions started to be a useful means to cumulate knowledge about auroras, such as Mairan did in the 18th century. Influenced by the experiments of Birkeland concerning the cathode rays, and by the theory of Arrhenius, based on the hypothesis of negatively charged corpuscles emitted by the sun and producing cathode rays in the terrestrial atmosphere, Nordmann was conducted to disqualify electric currents in the atmosphere as the cause of the auroras. Instead of this, he imagined that auroras are a luminescent phenomenon caused by cathode rays produced in the atmosphere by hertzian waves emitted by the sun. This hypothesis is to be contextualized in Nordmann researches: working first at the Meudon observatory with Janssen, Nordmann defended his thesis on the hertzian waves in 1903 (prepared with Henri Poincaré), and then worked at the Paris Observatory. For him, hertzian waves became a paradigmatic object, allowing the explanation of a lot of cosmic phenomena such as comets, nebulas, etc. For Nordmann, auroras make part of a larger epistemological problem: to explain cosmic appearances by the means of laboratory experiments renewed by the discovery of new corpuscles and new radiations. Larger studies will have to be devoted to describe precisely this analogical method.

Paul Villard is another French physicist who proposed at the beginning of the 20th century a theory explaining the northern lights. As the astrophysicist Henri Deslandres, he used the newly discovered cathode rays to explain such cosmic phenomena as auroras or comets. His theory is based on his work concerning the relations between cathode rays and a magnetic field, and can be called "cathodic electromagnetism"[5]. For Villard, northern lights are produced by the solar illumination of cirrus in the atmosphere, conducing to the production of cathode rays. Interacting with the terrestrial magnetic field, those corpuscles coil themselves in a particular tube trajectory, named *trochoïde*, producing visible rays in the atmosphere. He writes that "il résulte de cette étude que si des rayons cathodiques se produisent dans le champ magnétique terrestre, ils s'enrouleront en une spirale repliée en zig-zag de manière à former autour de la Terre une nappe de revolution limitée au nord et au sud par deux parallèles magnétiques d'intensité décroissante de l'ouest à l'est, et d'aspect tout à fait semblable à celui d'une aurore "[6]: his theory is guided and constrained by the theoretical problem of a mathematical description of the trajectory of a charged particle in a magnetic field, an is then a purely physical problem resolved by a mathematical analysis.

In the tradition instigated by Charles Fabry, physicists such as Jean Cabanne or Jean Dufay explained auroras in the subfield of atmospheric optics, more interested in the study of the atmosphere as an interactive place between heavens and earth, where the interactions between light and matter could easily be measured and observed: auroras, or northern lights, were an atmospheric phenomenon to be studied in the same way than the zodiacal light and the light of the night sky. For Daniel Barbier and Daniel Chalonge, auroras were studied because of spectroscopic researches that allowed to make analogies between stellar, solar and telluric atmospheres. Unlike Villard or Nordmann, who wished to explain natural phenomena by induction of laboratory, and so terrestrial, experiments, Barbier and Chalonge saw the atmosphere as a boundary place, between heavens and earth, and so between astrophysics and geophysics. They often insisted on this methodological aspect: the study of the stars needs precise measurements of the atmospheric absorption, or precise observations of the particles emitted by the sun seen as a singular star, making the study of auroras or atmospheric ozone necessary: "Nous avons entrepris, depuis plusieurs années, des recherches spectrophotométriques sur les étoiles des premiers types spectraux, dans un but purement astrophysique. Nous sommes cependant obligés, pour faire les corrections d'absorption atmosphérique dans l'ultraviolet, de déterminer quelle est, pour chaque soirée d'observations, la valeur de l'épaisseur réduite de l'ozone atmosphérique, et nous obtenons ainsi, accessoirement, des résultats intéressant la géophysique"[7]. Then auroras are not really studied for themselves, but because of the possibility to observe the sun by the means of the detection of solar particles in their interaction with the terrestrial atmosphere: "L'émission de particules électrisées par le soleil pose un problème très intéressant en soi-même et aussi à cause de l'influence qu'elle pourrait avoir sur l'équilibre des couches extérieures du soleil. En outre, la théorie pourrait montrer quel est le rôle de ces particules dans la formation des raies brillantes de certaines étoiles chaudes et des nébuleuses. […] Le seul phénomène qui se présente à

[7] Daniel Barbier, Daniel Chalonge, "Recherches sur l'ozone atmosphérique", *Le Journal de Physique et le Radium*, 1939, t.10, n°3, p.113.

l'état pur comme dû avec certitude aux particules émises par le soleil est l'aurore polaire. C'est à ce seul phénomène que nous allons demander des renseignements sur la nature des particules et en particulier sur le signe de leur charge et leur vitesse."[8] The same conclusions can be made about the method employed by Jean Cabannes, another student of Charles Fabry, and renowned for his experimental confirmation of the law of Rayleigh concerning the scattering of light by gases in the 1920's: for him, and his students after him, auroras and atmospherical phenomena are observed under the prism of the scattering of light. Indeed, atmosphere is therefore the place of the interactions of light and matter, permitting an easy study of light by the way of zodiacal light, light of the night sky or auroras. During a long part of his career, Cabannes applied recommandations made by Fabry at the beginning of the 20th century: "Le phénomène de la diffusion de la lumière par les gaz, dont la théorie a été faite par Lord Rayleigh, a conduit à l'explication de la lumière bleue du ciel. Je me propose de montrer que la même cause peut être invoquée pour expliquer un certain nombre de phénomènes naturels, et cela en faisant intervenir seulement des gaz dans un état d'extrême rarefaction"[9].

But, if practices are concerned, it will be interesting to focus the attention on Alexandre Dauvillier. For him, auroras were integrated in a new discipline: cosmic physics. Seen as a unitary theory, cosmic physics was built as a science of coordination and as a synthesis between astrophysics and geophysics. Auroras were so explained in the perspective of interactions between electrons projected by the sun, and terrestrial atmosphere. Dauvillier put the emphasis on cosmic physics as a field discipline: for instance, he wrote about Villard that "L'illustre physicien manquait de l'expérience des régions polaires et il sera toujours quelque peu imprudent de proposer une théorie de ce phénomène sans l'avoir longuement observé"[10] . He refused as well a too geometrical treatment of natural phenomena, a too theoretical explanation of them: "La théorie de P. Villard a été discutée par C. Störmer. Comme on le voit, une véritable théorie de l'aurore était édifiée, mais cette conception était trop théorique et les aurores ne présentent pas, dans la réalité, cet aspect géométrique simple."[11]

For Dauvillier, polar expeditions were a necessary step in the learning of a geophysicist because he saw his 'cosmic physics' as a science of adventure. He wrote about the training of students:

> "L'étude des aurores boréales les fera voyager et hiverner dans les régions polaires. Pour ma part, le souvenir de trois hivernages vécus, pendant la longue nuit polaire, en Laponie ou au Grönland, m'enthousiasme encore, et je n'ai pas renoncé au projet, caressé depuis longtemps, qui devait nous faire, le capitaine de frégate Habert, quelques collaborateurs et moi, séjourner toute une année exactement au pôle sud ! A l'exemple de leurs aïeux découvrant, au siècle dernier, le magnétisme du Globe, l'étude des rayons cosmiques leur fera parcourir les océans, gravir de hauts sommets, s'élever dans la stratosphère, en ballon ou en avion, s'enfoncer dans les mines profondes ou plonger en sous-marin. Je ne connais pas de programme d'action plus séduisant, offert à l'activité d'un homme de science, que cet alliage de recherche patiente et réfléchie, d'activité physique et de contemplation de la nature."[12]

He was himself implicated in numerous travels, such as the second International Polar Year in 1932-1933, during which he stayed 14 months in Scorseby Sund. But Dauvillier first travelled in 1931 to Sodankylä (Finnish Lapland) where he stayed few months. In 1934, he worked in Arosa (Switzerland), and returned to polar regions in 1934-1935, for a wintering in Abisko (Sweddish Lapland) with Daniel Barbier and Daniel Chalonge. But these scientific expeditions, characterising a field approach of his cosmic physics, are necessarily accompanied by laboratory experiments. Further researches will have to be raised to question the epistemological specificity of the science developed and promoted by Dauvillier. It can already be said that the lab experiments conducted by Dauvillier try to precise secondary phenomena occurring in the production of auroras: if his auroral theory is based on secondary electrons, the problem is not yet solved because of the lack of understanding of the permanent emission of high-energy corpuscles, of the nature of the exosphere, of the nature of secondary electrons emitted by this atmospheric layer, and of the turbulent regime that exists in those places where impacts between solar and terrestrial corpuscles occur. To precise the effects of these phenomena, Dauvillier was conducted to build an animated model named 'Terrella', allowing the reproduction of auroras according to the time and to the moment in the year. He could find important results with this model, such as the permanence and the rotation of the terrestrial corona, a luminous zone corresponding to the auroral zone, its changing dimension –larger in summer than in winter– and the displacement of the

auroral pole. His model was then used in a pedagogical way: Jean Perrin asked him to build an auroral synthesis device allowing the visualization of the path of the cathodic beam in the magnetic field of the earth.

As a conclusion, it can be said that the French approach of auroras is still to be questioned. Each of the styles seen above articulated various sites: laboratory, mountain observatories, polar and desert expeditions. Auroras allow science historians to go further in the description of the connections between the search of precision and universality by the use of multiple and singular sites[13]. Auroras will have, as well, to be integrated in the study of other boundary objects such as cosmic rays, ozone, zodiacal light, light of the night sky, because of their historical interest in the construction of hybrid sciences as astrophysics, geophysics and cosmic physics, and because of the possibility to know more about the emergence of complexity and interdisciplinarity at this moment.

THE HISTORICAL DEVELOPMENT OF LASER TECHNOLOGY AS AN EXAMPLE OF NON-CLASSICAL ENGINEERING SCIENCE[1]

Elena GAVRILINA
Moscow Bauman State Technological University, RUSSIA
e.a.gavrilina@gmail.com

Abstract

Laser is one of the important inventions of the 20th century. The creation of laser leads to the development of novel technological processes, new branches of industry and origin of the principal new mode of communications, which are very important for knowledge society. It is representative that in the 20th century five Nobel prizes for physics were given for laser investigation. It is well-known that classical engineering sciences are closely connected with natural sciences (especially with physics). At the same time engineering sciences have their own methodology and their own specific mode of knowledge organization –technological or engineering theory. The development of technological theory and practical applications of laser technology were going parallel. But the technological theory in laser technology is based on non-classical physics and can be regard itself as the new type of non-classical technology. This is the history about the non-linear direction from theoretical scientific knowledge to technological applications and the important role of scientific schools.

Formation and development of laser technology as an object of social and methodological analysis is chosen deliberately, because in our opinion laser technology represents a typical example of construction of a non-classical technical theory when “pure” science and engineering experiment are developed simultaneously, mutually enriching each other.

Let us review in more details the way of transformation of quantum physics theoretical postulates into one of the most considerable branches of modern technical theory –the theory of laser and optical-electronic devices and systems.

For the solution of this problem it is necessary to track all the way from emerging of an idea to its practical embodiment in the device or technology. And, in this case it is not a matter of separate inventions, discoveries and innovations, but rather a matter of formation of a highly-developed scientific and technical discipline with all its distinctive features: ascientific and engineering community, developed industrial structures, etc.

[1] This report is prepared for the project 09-06-00042 “Technoscience in Knowledge Society” of the Russian Foundation of Basic Research.

The approach offered by V. Gorokhov was a methodological basis for our research[2]. In this approach, it is important to take into account the external social conditions, apart from the internal logic of scientific development.

The importance of Einstein's ideas for the development of quantum electronics

In the beginning of the 20th century optics already had a rich history. Here we will not review a detailed analysis of the achievements of many great scientists, as they are well-known and described in detail many scientific and popular articles and books written "from within", i. e. by physicists, as well as "from the outside", i.e. by philosophers and methodologists of science.

We will review the origin of the theory of laser and optical-electronic devices and systems from the moment of occurrence of the idea which has subsequently become the key idea for this science and technology.

The basis of this research was brought to science by Einstein[3]. Actually, in 1905 he published an article "About one heuristic point of view, concerning occurrence and light transformations". In this article, the possibility of the existence of light quanta –photons– was considered. Although by then the concept of "energy quantum" was already known enough, introduced by M. Planck, Einstein's idea was negatively accepted by the majority of the leading physicists of that time. In many respects it was connected with the tremendous success of Maxwell's theory and its experimental confirmation by Hertz. In other words, the wave concept was the prevailing point of view on the subject of light nature. Therefore Einstein was exposed to numerous criticisms and sneers. Max Born, friend and colleague of Einstein, wrote "Nobody took Einstein's light quanta seriously" [4]. This citation illustrates the scepticism about light quanta which was general at that time.

However, the possibility of explaining the red threshold of photo effect only by quantum theory of light[5] made all physicists accept these "strange light quanta", at least as a working hypothesis.

Approximately since 1913 N. Bohr's publications about the quantum theory of electronic orbits in atoms and about the origin of spectral lines started to appear; in 1922 the Compton effect was discovered –all of them strengthening the position of photons theory. In 1916 Einstein published a small article[6], which was recognized as basic theoretical work on quantum electronics more than 40 years after its publishing. In this article Einstein indicated that besides spontaneous radiation of energy by molecules or atoms, induced radiation from a compelled substance also existed.

In classical physics it is considered that under the influence of electromagnetic radiation the atom passes from level E1 (low) to level E2 (high), thus there is energy absorption. The raised atom can spontaneously pass to one of the underlying levels of energy, thus radiating a light quantum. Light waves radiated by warm bodies are formed as a result of such spontaneous transitions of atoms and molecules. Spontaneous radiation of various atoms is not coherent. It is considered that the normal condition of atoms is unexcited (E1), and accordingly the majority of atoms are in it. Einstein showed that radiation of a different type is possible –induced radiation, i.e. transition E2 to E1. Thus it is not important how the atom is transferred to higher power level. The light wave is amplified as a result of this transition. Moreover, the induced quantum doesn't differ from an inducing photon: they coincide in propagation direction, in polarization, and in frequency. Electromagnetic waves, formed of such quanta, are considered coherent. This fact was proved by P. Dirac in 1927 [7].

And the last basic theoretical position, which confirms that there can be unlimited number of quanta in one oscillator field, was proved by Einstein in 1925[8].

These are the basic theoretical preconditions of emergence of quantum electronics and laser technique. But it was still quite far from practical realization of these postulates. The majority of physicists of that time regarded the above described postulates as a certainly "impracticable" part of the theory, as a rather curious consequence of the quantum doctrine, as a certain incident. It can be easily explained if we take into account the fact that a medium with inverse density of population (i.e. such medium in which the number of the excited atoms exceeds number of atoms at the bottom power level) does not exist in natural physical conditions. And actually scientists of that time were focused in a greater degree on

problems of another sort. However, there are always a few people who solve a problem considered unpromising by others. Actually, we will speak further about them.

Experimental confirmation of existence of inverse medium and possibility of compelled radiation

In 1928 Rudolf Ladenburg and his pupil Hans Kopferman, while studying dispersion in the electrical excited gases, experimentally observed a negative dispersion in a helium and neon mix that showed the possibility of creating a medium with inverse density of population[9].

Indirect experimental acknowledgement of the possibility of creating mediums with inverse density of population also confirmed the basic possibility of compelled radiation. But Ladenburg worked with the spectroscope and he used to experiment with natural (i.e. spontaneous) electromagnetic radiation and, therefore, he could not estimate prospects of generators of compelled radiation of electromagnetic waves, since compelled radiation was so weak that it could be neglected in favour of spontaneous radiation. This result remained in the investigated area of science and technology only as "a curious fact".

Works of Soviet physicist Valentin Fabrikant became the next period in the development of laser technique [10].

V. Fabrikant graduated from the physical and mathematical faculty of the Moscow State University, and was a pupil of Sergey Vavilov. Basic questions in his sphere of interests were connected with optics of gas discharge and, more precisely, with the phenomenon of electroluminescence and creation of practical samples of luminescent lamps. During this research, Fabrikant became interested in the possibility of strengthening optical radiation at its passage through a gas medium. In 1939 Fabrikant defended his doctoral thesis, where apart from generalization of Ladenburg's experimental results, he also described situations in which induced radiation would prevail over the spontaneous one. Besides, Fabrikant directly specified mediums where it is possible to create inverse density of population, i.e. he specified the mediums which strengthened, instead of absorbing, passing radiation [11].

However, these results had no practical outcome for the achievement of particular objectives; in addition, the Great Patriotic War began, and no special attention was paid to the works of Fabrickant. After the war Vladimir Fabrikant together with the laboratory worker Fatima Butaeva renewed the work on research on optics of gas category and mediums with negative dispersion (1947)[12]. But the works of Fabrikant and his colleagues fully contradicted the dominating approaches of that time[13].

It is easy to assume that such a reaction of guild fellows for a long time postponed recognition of the importance of this research. Scientific magazines refused to publish articles about substances with negative light absorption, and their authors were in an unenviable position.

Actually these incidents represent an impressive example of an inopportune discovery, as well as the influence of the paradigm (in manner of Th. Kuhn) and the academic environment on propagation of scientific ideas.

As a matter of fact, the main operation principles of the instrument (which was afterwards named after the English acronym LASER –Light Amplification by Stimulated Emission of Radiation) were formulated.

The word "laser" was used for the first time by Gordon Guld, post-graduate student of Columbia University. Generally Guld's story is quite interesting, and it could be an example of academic community influence. In November, 1957 he completely single-handedly described and designed an instrument now known as laser. However, without significant authority in scientific circles he was afraid to publish the results in the form of a scientific article. However he notarized all the calculations and drawings. It didn't bring him scientific glory, although on the basis of these records Guld was able to receive a set of patents connected to the usage of lasers that made him rich afterwards.

Probably, if S.I.Vavilov, who always supported V.A.Fabrikant, hadn't died in 1951 the Nobel committee nomination of 1964 would have included other names. And it is likely that the invention of laser would have happened a bit earlier.

But history doesn't know of a subjunctive mood. Therefore we will review the further development of the ideas which led to the creation of laser technology.

In 1950 the French optician Alfred Kastler offered a method of optical pumping of a gas medium, which later (in 1966) received the Nobel Prize[14].

Despite the impressive success in research of the nature of electromagnetic radiation, the key step in creation of generators of light in optical band wasn't made yet! Not least of all, it happened because almost all researches in this area were led by scientists-opticians, and for them amplifying of optical radiation was represented by a natural part of the optical system, and the basic restriction for the development of these instruments was the dominating paradigm, as this amplifier didn't present any independent value for them.

Creation of the first generators of microwave and optical radiation

The solution for the objective of creating optical radiation generators, which was not yet formulated, came from the adjacent area of physics –radio-spectroscopy.

Radio-spectroscopy is an area in radio physics which was developed by outstanding Soviet scientists L. I. Mandelshtam and N. D. Papaleksi. In their oscillations laboratory in the beginning of 1939 worked A. M. Prokhorov[15]. In 1946 he defended his master thesis, and his doctoral thesis in 1951. The possibility of synchrotrons' usage for generation of millimetre waves was the subject of Prokhorov's research, the results of which were included into his doctoral thesis.

A. Prokhorov began to work in the field of spectroscopy of gases almost simultaneously with research in the area of accelerators physics. An object of research is rotational and oscillating spectra of molecules. It is necessary to note that radio spectroscopy started to develop vigorously after the Second World War. Not least of all, it is connected with the fact that for the research of gas spectra well-developed applied methods of radiolocation and radio engineering were used.

The main challenge for physicists consisted in the impossibility of creating a sensitive enough method to register the absorptive passages in molecules because of molecule concussions in gas and the Doppler Effect, i.e. it was not possible to take sufficiently precise measurements. This matter was worked on by A. Prokhorov and his pupil and colleague N. Basov. Actually, they solved the objective of resolution enhancement of radio spectroscopes. During this work there was the assumption that broadenings of the spectral lines (because of molecule concussions and the Doppler Effect) can be avoided if instead of gas a bundle of molecules was used.

Actually, it was the beginning of quantum electronics development, but it is interesting to note that the idea of a quantum generator emerged as a by-product of the activity which was aimed at the solution of an absolutely different objective.

Two articles (J. P. Gordon, H. J. Zeiger, and C. H. Townes "Molecular Microwave Oscillator and New Hyperfine Structure in the Microwave Spectrum of NH3"[16], and N. G. Basov, A. M. Prokhorov "The Molecular generator and amplifier"[17]) were published in 1954, absolutely independently from each other, with a difference in some months.

These articles were of theoretical nature, and the device –a molecular generator which radiated on wavelength of 1,25 cm, or the ammoniac maser (from English Microwave Amplification by Stimulated Emission of Radiation)– was created independently in 1954 by C. Towenes' group in the US Columbia University and by A. M. Prokhorov and N. G. Basov in the Moscow Physical institute.

So, we will sum up. In 1954 A. M. Prokhorov and N. G. Basov, and C. Townes, J. Gordon and H. Zeiger[18] offered methods of formation of molecular bundles with subsequent sorting of excited and unexcited molecules and passage of bundle of excited molecules through a cavity resonator. Then for the first time it became possible to integrate the idea of

induced radiation and inverse density of population with the ideas representations about resonators, feedback and generation of coherent electromagnetic radiation.

During the same period A. M. Prohorov together with N. G. Basov developed an exhaustive theory of molecular generator and radio frequency radiation amplifier. Then they patented a new method of creation of inverse density of population –optical pump under three-level circuit[19].

Nevertheless, it was 5 years before the creation of generators in optical radiation. There were a number of reasons for that. The first was described by C. Townes in his Nobel lecture very explicitly:

> "Until about 1957, the coherent generation of frequencies higher than those which could be obtained from electronic oscillators still had not been directly attacked, although several schemes using molecular-beam masers for the far infrared were examined from time to time. This lack of attention to what had been an original goal of the maser came about partly because the preliminary stages, including microwave oscillators, low-noise amplifiers, and their use in various scientific experiments, had proved so interesting that they distracted attention from the high-frequency possibilities"[20].

The other two problems of passage of radiation in optical band were mentioned by A. M. Prokhorov in his Nobel speech:

> "One might think that after the successful construction of masers in the radio range, there would soon be made quantum oscillators (lasers) in the optical range as well. However, this did not occur. Those oscillators were constructed only 5-6 years later. What caused such a delay? There were two difficulties. One of them was as follows: at that time no resonators for the optical wavelength range were available. The second difficulty was that no methods were immediately available for gaining an inverse population in the optical wavelength range."

Let us consider firstly the question of resonators. It is well-known that radio engineering started its development from the region of long waves, where resonators were used in the form of self-inductance coils combined with condensers. In that case the size of the resonator is much less than one wavelength. With the development towards short waves cavity resonators were used. They are closed volume cavities. The size of those cavities was comparable with a wavelength. It is quite clear that with the help of such cavities it is impossible to advance into the region of very short waves. In particular, it would be impossible to reach the optical range.

In 1958 it was proposed the so-called open type of cavities for masers and lasers in the region of very short waves. Practically speaking, this is Fabry-Perot's interferometer; however, a «radio engineering» approach made it possible to suggest the use of such a system as a resonator. Afterwards, spherical mirrors were used together with plane mirrors. The size of these resonators is much more than that wavelength"[21].

Alexander Mihajlovich was modest because it was him who offered to use Fabry-Perot's interferometer, widely known in the world of optics, as open resonator in June, 1958. The basic function of this device consists in the selection of radiation depending on the wavelength[22].

For the sake of justice it is necessary to mention that in the same 1958, although in December, A. Schawlow and C. Townes in the magazine *Physical Review* published the article «Infrared and optical masers». In abstract of this article it was specified:

> "The extension of maser techniques to infrared and optical region is considered. It is shown that by using a resonant cavity of centimeter dimensions, having many resonant modes, maser oscillation at these wavelengths can be achieved by pumping with reasonable amounts of incoherent light. For wavelengths much shorter than those of the ultraviolet region, maser-type amplification appears to be quite impractical. Although use of a multimode cavity is suggested, a single mode may be selected by making only the end walls highly reflecting, and defining a suitably small angular

aperture. Then extremely monochromatic and coherent light is produced. The design principles are illustrated by reference to a system using potassium vapor"[23].

As to the second difficulty, the way out of it lay on a way of an uncountable set of researches of spectroscopic properties of various materials. Gases (we will recall Fabrikant) and crystals were the most researched at that moment. Therefore the main experiments were made with them.

The first generator of optical radiation was created on the crystalline active medium. Laser was constructed in May, 1960 in the USA by Theodore Maiman. As the active medium it used an artificial ruby crystal (aluminum dioxide with chrome impurity) which was pumped by means of a normal flashlamp, and as the resonator a mirror covering put directly on polished end faces of the crystal was used. Maiman's Laser was impulse and generated a wavelength of 0,6943 microns, i.e. radiated red light[24].

In the same 1960, in December, employees of the "Bell Labs" laboratory Ali Javan, William Bennett, and Donald Herriott showed helium-neon laser where inverse density of population was created by electrical discharge in a low pressure gas compound[25]. It is necessary to note that the construction of this laser almost completely repeated that of Fabrikant, Butaeva and Vudynsky.

All these events meant that the basic boundary was crossed. Physicists and engineers managed to receive radiation generation in optical band. This stimulated radiation differed from the known before spontaneous variety of characteristics (monochromaticity, coherence, directivity and brightness). And these characteristics allow very active industrial use of lasers. It is necessary to note that the creation of new lasers continues nowadays too, but it is already a routine scientific and technical activity.

* * *

In the end of the article we'd like to mention once again that the theory of laser and optical-electronic technology represents a non-classical scientific and technical discipline. It initially progressed not under the influence of a single basic scientific theory, but under the influence of an interdisciplinary area of research, based on the data of various technical and theoretical models. Simultaneously with scientific research industrial research was carried out as well, and both types of researches mutually influenced each other. As a matter of fact, the theory of laser and optical-electronic technology was one of the first scientific and technical theories of the new class, and consequently the analysis of its formation is deemed important for understanding the logic of scientific and theoretical knowledge development.

KNOWLEDGE SYSTEMS IN FLUX: SWEDISH PHILOSOPHY OF SCIENCE AND HUMANITIES DRIFT APART. A HISTORY OF THE CHALLENGE OF THE MODERNIST WORLD VIEW

Victoria HÖÖG
Department of Philosophy and History of Science, Lunds Universitet, SWEDEN
victoria.hoog@fil.lu.se

Abstract

This paper focuses on the concept of objectivity to illuminate the interdisciplinary negotiations between academic subjects in Sweden from the 1960s to the present. The concept of objectivity held a central theoretical space in almost all academic subjects in Sweden during the postwar period. A salient person in the discussion of the 1970s was Gunnar Myrdal who had focused on the relation between values and the social sciences since the 1930s. For Myrdal, value premises worked as a positive normative ideal. In An American Dilemma *he referred to the American democratic "creed" as a substantial inspiring framework for progressive social change to solve American racism. In 1968 Gunnar Myrdal published* Objectivity in Social Research. *Values were presented as obstacles –yet possible to overcome if the researchers openly declared their valuations. Myrdal's book is one of the first examples of how the concept of objectivity became an engaging topic for debate in the academic circles during the 1970s. Myrdal's view fitted into the traditional view to represent science as a vocation –as Max Weber famously expressed it.*

A suggestion is that the concept of objectivity functioned as a "prism" that upheld a shared academic public space between philosophy, natural sciences, humanities and social sciences. Three factors –the dominance of the philosophy of science within philosophy, Gunnar Myrdal's lifelong interest in values and the new left movement's attack on the belief of an objective science– made the question of scientific objectivity to a public and scholarly issue for debate in Sweden and contributed to uphold a shared communicative space.

However, during the 1980s the discussion about objectivity went out of tune. New competing knowledge systems emerged with hermeneutics, discourse theory, marxism and Thomas Kuhn's paradigm theory. They supplied the humanities with new theoretical tools and the vocabularies were drifting apart.

As a result, a gap between analytic philosophy's quest for impartial truth vs. humanities' and social sciences' defense for including history, values and local practices in the analysis emerged. The new generation of people in humanities founded their own philosophies, and neglected the established analytic philosophy. However, in the last decade questions about objectivity have arisen anew, in medical research and climate science. That might indicate that a renewed scholarly public conversation between different academic topics will have space for an alerted philosophy of science.

Introduction

During the last decades philosophy of science and history of science have drifted apart in Sweden. This state of affairs provides the point of departure for this article, which focuses on the intellectual postwar history of philosophy of science in the Anglophone world and Sweden. The specific question is: How did analytic academic philosophy become isolated from the other humanities? One salient feature has been the questioning of relevance of the analytical philosophy of science by the other humanities, particular history of science. According to humanities in general and history of science in particular, the ambition to be a strong scholarly allied to the natural sciences, since the interwar period have resulted in a technical formal philosophy of science. Analytic philosophy of science proceeds its task as sciences would consists of pure rational content; hence not reflecting how much the sciences cognitive content is determined by its practices, let it be laboratory practices or machine availability.

A thesis in this article is that the tension and the resulting gap can be interpreted in terms of conflicting world views, not only in different cognitive content. The logical positivists and Karl Popper shared a belief in modernity's prime virtues; rationality and reason were incarnated in science. Science was the new frontier against old-fashioned obscure metaphysics represented by idealistic history and philosophy.

The article starts with presenting the logical positivism in Vienna and Uppsala, and in particular arguing for that their philosophical framework was intertwined with a belief in modernity. Philosophy in the shape of the Vienna circle was a part of the European modernism which settled the agenda for the twentieth century Western culture. Usually architecture, art and changing social life styles are considered as the prime carriers of modernity. The thesis is that analytical philosophy of science had a "modernist framework" that helps to understand the rise and the still existing gap between analytical philosophy and its counterparts in the humanities. Rudolf Carnap's *The Logical Construction of the World* illustrates this modernist creed. Also Karl Popper –the logical positivists' first combatant– belonged to a modernist world view; they shared the belief in sciences as the highest knowledge standard, distinguished by its rationality. At the famous colloquium in London 1965 the clash in world views was evident. Karl Popper labeled Thomas Kuhn's view on scientific change as "mob-psychology."

During the twentieth century Swedish philosophy was influenced by the Vienna circle as well as its successor analytical philosophy, a development it shared with the US. A strong component in this common framework was the modernist belief in scientific knowledge as value free. In the nineteen sixties new competing knowledge system emerged; hermeneutics, discourse theory, Marxism and Thomas Kuhn's paradigm theory. They supplied humanities with new theoretical tools. Analytic philosophy of science had to leave room for diverging vocabularies with deviating content. The analytic philosophy of science kept to the modernism belief in the sciences as superior form of knowledge, representing the highest available forms rationality and objectivity.

As a result, a gap emerged between analytic philosophy's quest for impartial truth and the humanities' and social sciences' defense for including history, values and local practices in the analysis. The new generation in humanities founded their own philosophies, and neglected the established analytic philosophy. Instead they highlighted that social practices and material conditions were cognitively relevant for understanding the history of science, a view out of tune with modernism. The article ends by discussing what sustains this academic gap that emerged that I claim is a result of a clash between different world views.

The Logical Positivists in Vienna and Uppsala

The first generation of logical positivists shared a conviction that philosophy of science mattered beyond the academy. The position has been stressed in recent research about the logical positivists (Giere & Richardson, 1996; Heidelberger & Stadler, 2002). The core circle of logical empiricists consisted of Moritz Schlick, Rudolf Carnap, Kurt Gödel, Philipp Frank (brother of Joseph Frank), Otto Neurath, Hans Reichenbach, and Carl Hempel. They repudiated parts of the existent academic philosophy, claiming that it represented a collection of mainly non-testable propositions, infused by metaphysical assumptions (Reisch, 2005). The modern task as philosophers of science was to design conceptual tools to evaluate knowledge claims, and hence demarcating scientific knowledge from less certain knowledge. However, the application was not restricted to science areas. The philosophically elaborated criteria of meaning, testability of facts and theories was intended to be applicable beyond the academic circles. Philosophy of science was a firm allied in the urgent contemporary fight against political persecution and antidemocratic movements, present in Europe in the 1920s. The positivists were radicals viewing science as an allied to create a better future. All of them more or less, forged their institutional connection to various cultural and political commitments.

The members of the Vienna circle viewed the natural sciences as a forceful weapon against the reigning obsolete idealism in humanities –and expanded the task of the philosophers to clean philosophy from outdated beliefs in philosophy. In 1929 Rudolf Carnap wrote in the preface to *Aufbau*:

> Whence then our confidence that our call for clarity, for a science that is free from metaphysics will be heard? It stems from the knowledge or, to put is somewhat more carefully, from the belief that these opposing powers belong to the past. We feel that there is an inner kinship between the attitude on which our philosophical work is founded and the intellectual attitude which presently manifests itself in entirely different walks of life; we feel this orientation in artistic movement, especially in architecture, and in movements which strive for meaningful forms [*Gestaltung des menschlichen Lebeen*] of personal and collective life, of education and of external organization in general. We feel all around us the same basic orientation, the same style of thinking and doing… Our work is carried on by the faith that this attitude will win the future (Carnap, 1967).[1]

The quote illustrates how the Vienna circle viewed the value system of science and culture; namely to be closely intertwined. The Viennese philosophers viewed their task to design philosophical tools intended to sort out rational knowledge from irrational metaphysics. According to them Europe more than ever needed criteria for meaning, facts and truth to defend political and social liberty against anti-democratic movements. They were radicals who considered the sciences as their allies to create a better future.

The Uppsala version of the Vienna circle distinguished itself for analytical truth seeking, focus on scientific epistemology and a belief in the accumulation of scientific knowledge and a hostile attitude to metaphysics. In the search for a unifying scientific principle the natural sciences were the allies that detached the philosophers from nationalistic historians. In Sweden Axel Hägerström in the 1920s, well repudiated philosophy professor at Uppsala University, affiliated with the Social Democratic Party, was the first within the academic philosophy to pick up the new radical trends from Vienna circle. He conquered a public space for the Swedish philosophy at the beginning of the twentieth century. Philosophy and the Swedish Social Democratic party shared the spirit of the time: the modernistic and an anti-metaphysical attitude merged and supported by a deep belief in scientific progress.

Hägerström is famous for his "value nihilism", i.e. that judgments about good, bad, right or wrong could not be judged false or true. Values were expression for emotions, not objectively true. They belonged to metaphysics. Hägerström's motto expressed rhetorically his standpoint: "Metaphysics ought to be destroyed" (Cassirer, 1939).

In Sweden's other university, Lund university, logical empiricism was introduced by the journal *Theoria*, founded 1935 (Manninen & Stadler, 2009 p. 69). The following year, in 1936, Otto Neurath wrote a descriptive historical presentation of logical empiricism for the journal, published in the first issue translated into Swedish (Ibid. p. 78.) In both countries, Austria and Sweden, philosophy of science was a part of a social movement to modernize and democratize the present society.

When the Neo positivist synthesis of formal logic and empiricism was questioned by Karl Popper in 1935, the basic problems of epistemology were re-casted. Roughly, instead of verification as the principal scientific methodological tool, falsification was suggested as the main scientific principle. If a proposed theory resisted falsification, it had to be accepted. Yet, a scientific attitude regarded all scientific knowledge as falsifiable in principle; an ultimate truth for science was neither needed, nor desirable (Popper, 1935). Popper distinguished the scientific method as the hallmark for scientific knowledge; the method generated the border between science and other forms of knowledge. However, even if Karl Popper represented an epistemic break with the logical positivists, the continued focus was on formal logic and empiricism. Another strong continuity is the normative ethical framework, to view the sciences and philosophy of science as the modernist challenger against conservatism and antidemocratic movements.

For long Karl Popper was quite unknown outside the established philosophers' circles. His international breakthrough came first in the 1960s. The two key events were, firstly, the positivism dispute which started in Germany 1961, when Jürgen Habermas made Popper to a positivistic icon, and secondly, when Thomas Kuhn's paradigm theory questioned the established story line of history of science, which Karl Popper was a representative for, as most Western philosophers at the time. At the symposium in London 1965 the different world views were distinctly exposed (Adorno, 1976; Lakatos & Musgrave, 1970).

---

[1] Quoted from Galison "Construction Modernism: Cultural locations of *Aufbau*,", in Ronald N. Giere & Alan W. Richardson 1996, p. 34.

Philosophical modernism challenged: Kuhn against Popper at the London symposium 1965

One key event that made both Karl Popper and Thomas Kuhn to academic celebrities was the symposium Imre Lakatos arranged in London 1965.[2] The symposium arranged by Lakatos gave Thomas Kuhn's paradigm theory the salient position together with Karl Popper falsificationism. The other participants were mainly philosophers of science, among them Paul Feyerabend, Stephen Toulmin and Lakatos. No historian of science participated. In his talk Kuhn focused on the differences between him and Popper. For a reader of today it sounds astonishing to hear that Kuhn asserted that he and Popper were regarded as a kind of theoretical pair, especially on the logic of scientific discovery. Kuhn sets his task to elaborate the supposed differences. He emphasizes the scientists' commitment to a tradition, which is a crucial difference to Popper. If they would act as Popper claims, science would be in permanent revolution, which would make progress impossible. According to Kuhn, mature science is characterized by puzzle solving within a paradigm and not revolutions which only occasionally occur. Normal science represents genuine science and is characterized by puzzle solving. The puzzle solving is not an extra rational activity, but relies on the skills the scientist is trained to achieve by textbook reading and established laboratory practice. Scientists behave only as philosophers when they "must choose between competing theories" (Lakatos & Musgrave, 1970, p.7). Kuhn asserts that Popper's view of science is taken from those rare moments of revolution. Tyco Brahe is more representative in the history of science than Copernicus (*Ibid*. p. 5).

In connection to this claim Kuhn poses the question whether rationality is a non-historical concept. His example shows that the concept needs an historical contextualization. Kuhn asserts that the astrologers' explanation of their failure was not unscientific and irrational. Astrology was a craft with close resemblance to meteorology and medicine. Its theory "provided a rationale for various craft-rules which governed practice" (*Ibid*. p. 8.). However, still the theory was too wide, and lacked puzzles to solve.

Kuhn addresses the question under what circumstances does a scientist abandon a theory? His answer is forceful and attacks Popper's position. Popper's theory rests on the assumption that theories can be formulated as syntactical judgments. Doubting the possibility of theories in syntactical forms, he accuses Karl Popper to have produced "not logic of knowledge, but an ideology" (*Ibid*. p.15). Refutation of a theory requires it to be "fully articulated logically –in practice "no scientific theory satisfies these rigorous demands" (*Ibid*. p. 16). Sir Karl has "erred by transferring selected characteristic of everyday research to the occasional revolutionary episodes… after ignoring the everyday enterprise entirely" (*Ibid*. p. 19).

What Kuhn is asserting is that a prominent philosopher of science confuses theory with ideology, an astounded comment to a philosopher who had a solid reputation for warning against the political dangers of confusing science and politics, incessantly warning for that other than liberal political commitment represented an unceasing threat to an open liberal society. Another participant, John Watkins, summarized the different positions: "What is genuinely scientific for Kuhn is hardly science for Popper and what is genuinely scientific for Popper is hardly science for Kuhn" (*Ibid*. p. 29).

Stephen Toulmin is stressing the normative dimension of science, indicating that normative and descriptive views of science are unintentionally mixed together. Maybe "philosophy of science is concerned with the questions what consideration *should properly* determine the selection" … and "the psychology or sociology of science … that in fact settles the matter" (*Ibid*. p. 46). A taste of the coming science wars in the 1990s between the later founded "sociology of scientific knowledge" (SSK) and philosophers of science can be imagined.

In his witty and incisive reply Karl Popper rejects Thomas Kuhn's notion of normal science. He attacks the Kuhnian concept of normal science as representing the logic of historical relativism. His argument runs as follows. History of science doesn't support Kuhn's view (*Ibid*. p. 53ff). Normal science is not normal. Kuhn's thesis that sociology and psychology matters most in normal science rest on the wrong view that scientists are logically forced to accept the framework. The wrong assumption is that no discussion is possible between frameworks.

This thesis is logical, not factual. The myth of the framework is the central bulwark of irrationalism. Frameworks can be discussed. Comparisons between different frameworks are possible. Even totally different languages are not untranslatable. According to Popper "we are prisoners in a Pickwickian sense: if we try, we can break out of our framework at any time" (*Ibid*. p. 56). Popper ends by comparing science and religion. Even if intellectual revolution looks like religious conversion, we can evaluate critically and rationally. "Logic of Discovery has little to learn from Psychology of Research; the latter has much to learn from the former" (*Ibid*. p. 58).

Imre Lakatos is still more straightforward about the supposed negative implications of Kuhn's theory. His paper is the most extensive and discusses almost every detail in Kuhn's book, but the beginning sets the critical framework. According to Lakatos, Popper represents the critical rational knowledge standard in the sciences that should pave the way for the rest of

---

[2] The proceedings are published in Imre Lakatos & Alan Musgrave (eds.) *The Criticism and Growth of Knowledge.* Cambridge: Cambridge University Press, 1970.

the society. It was a standard with flaws and failures, but the best available in the human world. In the aftermath, his comment on the differences between Popper vs. Kuhn seems almost clairvoyant in its prospective. Lakatos asserts that:

> The clash between Popper and Kuhn is not about a mere technical point in epistemology. It concerns our central intellectual values, and has implications not only for theoretical physics, but also for the undeveloped social sciences and even for moral and political philosophy … truth lies in power. Thus Kuhn's position vindicates, no doubt, unintentionally the basic political *credo* of contemporary religious maniacs ('student revolutionaries')… Kuhn doesn't understand a more sophisticated position … the rationality which is not based on 'naïve' falsificationism (Lakatos & Musgrave, 1970, p. 93).

Contrary to Lakatos' fear, Paul Feyerabend is pleased to find that he and Thomas Kuhn are on the same side, against the Popperians and the rest of the philosophy of science establishment. Feyerabend objects to Kuhn's view on normal science as puzzle solving within a monolithic theory. Normal science is not even a historical fact. He credits Kuhn for putting light on the "conservative and anti-humanitarian element in mature science", but Kuhn "has misinterpreted the relation of this element." Knowledge grows by the "active interplay of various tenaciously held views (*Ibid*. p. 203). In this view, he is not too far from Popper's falsificationism, which requires the possibility of easily emerging new bold hypotheses. Against the claimed rationality among the Popperians, Feyerabend argues that it is "not necessary arguments which cause us to adopt new standards." He writes:

> Moreover, it is likely that catastrophic changes, frequent disappointment of expectations, crisis in the development of our knowledge will change and, perhaps, multiply reaction patterns (including patterns of argumentation) just as an ecological crisis multiplies mutations. This may be an entirely *natural* process, like growing in size, and the only function of rational discourse may consist in increasing the mental tension that precedes *and causes* the behavioral outburst … Does not the occurrence of such a change show that science which, after all, is a part of the evolution of man, is not entirely rational and cannot be entirely rational? (*Ibid*. p. 217).

Feyerabend made the Popperians and the logical positivists to a common target. The failure of contemporary philosophy of science, inherited from the logical positivists, is this sulky insistence of rationality as the sole reigning force in science. In that claim he was one with the young generation who looked for a theory that situated science within societal context. Feyerabend disqualifies Kuhn for that position and reserves it for himself, displaying sensitivity for the spirit of the radical 1960s. In situating Karl Popper in the same theoretical camp as the logical positivists Feyerabend anticipated a dominant track in the 1970s radical student movement, namely "the positivism criticism." In Sweden almost no one outside the philosophers' circles held Popperianism and positivism apart.[3]

None of the other participants denied that science contained sociological aspects. The question was how much a sociological perspective mattered in philosophy of science, not if it mattered at all. The common concluding opinion underlined the secondary importance. Science had a permanently challenging character. What Kuhn did was to challenge this modernist dogma about sciences special progressive and ethical character. The elevated status of science was questioned.

Concluding remarks

The promotion of a scientific world view was an important part of the modernism in the beginning of the twentieth century. Modernism provided the sciences with a general framework that offered a place for sciences in the broader culture, also committed to social justice, political freedom and equality. In Europe these liberal secular values since the Enlightenment have been strongly intertwined with a deep belief in the sciences as a progressive liberating societal force.

The belief in reason –and the accompanied optimistic vision of a social and political justice in a progressive society with help from the sciences was the granted framework for the analytical philosophy of science in Sweden in the 1960s and 1970s. A close companion to the belief in reason and rationality as distinct features of science was the belief in objectivity. Taken together as a companion to the scientific world view, objectivity made a powerful case for the inevitable value of science.

Kuhn's paradigm theory together with Marxism and Foucault's discourse theory supplied the humanities and social sciences with new theoretical tools to challenge the modernist belief in progress, embedded in the analytical philosophical view. The humanities interpretation of Kuhn emphasized epistemic and moral value relativism and questioned the standard definition of rationality as a universal non-biased science property leading to knowledge progress.

---

[3] Feyerabend's position is reflecting Jürgen Habermas position and the "Positivismusstreit" that had emerged in Germany 1961, see (Adorno 1976).

The outcome were different epistemic cultures, parallel but not communicating with each other. Philosophy of science and history of science developed in different directions. For history of science it was a successful separation. The research focus shifted from theory and concepts to practice, experiment, and laboratory and context dependence. A new theoretical vocabulary was imported from anthropology, sociology and history, not philosophy of science. Humanities developed their own philosophical legitimacy and competence, independent of analytical philosophy. A result is that no shared public academic exchange zone exists today between philosophy of science and humanities in Sweden.

A conclusion of the above story is that the philosophical content is not decisive for the public relevance or popularity. The emigrants from the Vienna circle lost their cultural sphere when they arrived to the US. Analytic philosophy of science lost its central role for the other humanities when the left winged inspired cultural meanings superseded modernism. Nowadays French continental philosophy is considered more available for the public by virtue of its existential dimension, despite its notorious indistinct style of writing. The popularity might depend on the fact that continental philosophy is tuned with the present world view, globalism in late modern capitalism.

Abstract

Nanotechnology is at the same time a field of scientific knowledge and a sphere of engineering activity, in other words –NanoTechnoScience– similar with Systems Engineering as the analysis and design of complex man/machine systems but now as large-scale micro- and nanosystems. In nanotechnoscience, on the one hand, explanatory models of natural phenomena are drawn up and predictions of the course of certain natural events on the basis of mathematics and experimental data are formulated as in classical natural science, and, as in the engineering sciences on the other hand, not only experimental arrangements are constructed, but also structural plans of new nanosystems previously unknown in nature and technology.

In nanotechnoscience, on the one hand, explanatory models of natural phenomena are drawn up and predictions of the course of certain natural events on the basis of mathematics and experimental data are formulated as in classical natural science, and, as in the engineering sciences on the other hand, not only experimental arrangements are constructed, but also structural plans of new nanosystems previously unknown in nature and technology.

The operation of nanotheory

The operation of nanotheory is realized by the iteration method (see Fig. 1). First, a specific engineering problem is formulated. Then it is represented in the form of the structural plan of the nanosystem, which is transformed into an idea about the natural process reflecting its performance. To calculate and model this process mathematically, a functional

[1] This article is prepared for the project 09-06-00042 "Technoscience in Knowledge Society" of the Russian Foundation of Basic Research.

diagram is constructed. Consequently, the engineering problem is reformulated into a scientific one, and then into a mathematical problem solved by the deductive method. This path from the bottom to the top represents the analysis of schemes (the *bottom-up* approach)[2]. The opposite direction –the synthesis of schemes (the *top-down* approach)– makes it possible to synthesise the ideal model of a new nanosystem[3] from idealised structural elements according to the appropriate rules of deductive transformation, to calculate basic parameters of the nanosystem, and to simulate its function.

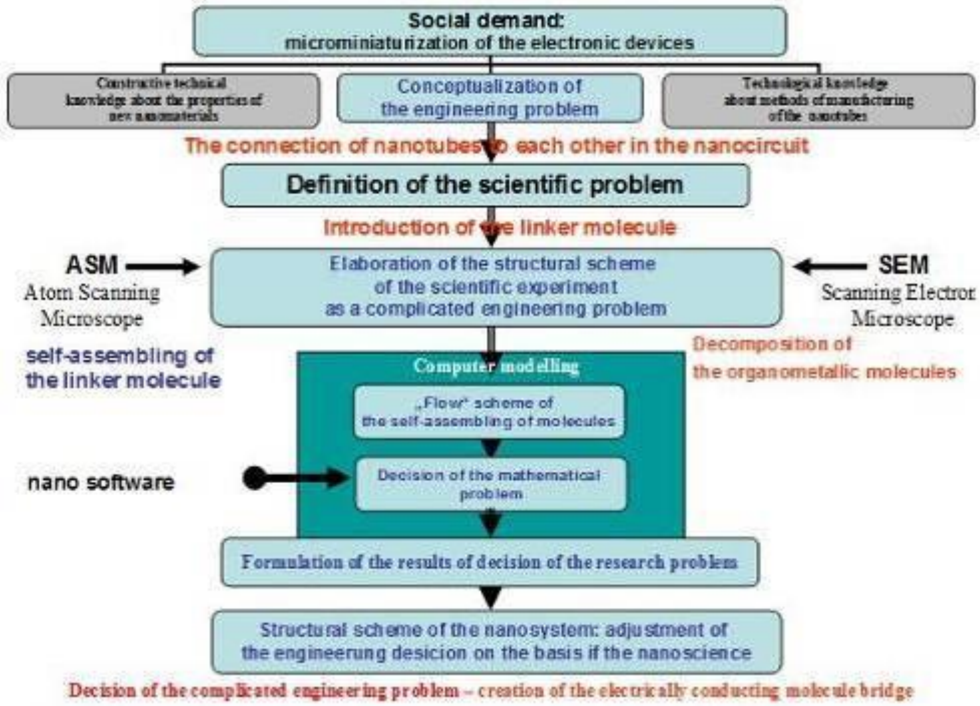

Fig. 1: Operational Algorithm of the NanoTechnoScience Function.

In natural scientific theory, flow charts are of primary importance, but structural plans are not. Both the mathematical apparatus and experiments are, for natural scientists, merely a means of prediction and explanation of the natural processes. For example, Hertz worked in principle as an engineer when he designed new experimental equipment. But he did not intend to find a technical application for his experimental devices. One of the major problems of well-developed engineering theory lies in the "copying" of type structural schemes for various engineering requirements and conditions. Then, the solution of any engineering problem, the construction of any new system, will be supported theoretically. This is the essence of the constructive function of engineering theory (theory in engineering science), its guidance of engineering practice. Its solution is cast into practical-methodical recommendations (for the designer, inventor, production engineer, etc.). A class of hypothetical technical systems must correspond to its abstract objects which have not yet been realised. In engineering theory, therefore, not only analysis is important, but above all, synthesis of theoretical schemes of technical systems.

In nanotechnoscience constructs from various scientific theories –classical and quantum physics, classical and quantum chemistry, structural biology, etc.– are used, whereas, in nanosystems, different physical, chemical and biological processes take place.

[2] For instance, this can be the investigation of "the possibility of connecting nanoparticles in series and in parallel configurations, acting as nanocircuit elements" (see: Alessandro Salandrino, Andrea Alù, Nader Engheta. *Parallel, Series, and Intermediate Interconnections of Optical Nanocircuit Elements Part 1: Analytical Solution*. http://arxiv.org/ftp/arxiv/papers/0707/0707.1002.pdf).

[3] Nanocircuit synthesis can be, for example, a synthesizing nanocircuit elements in the optical domain using plasmonic and non-plasmonic nanoparticles (see: Nader Engheta, Alessandro Salandrino, Andrea Alù. *Circuit elements at optical frequencies: nano-inductors, nano-capacitors and nano-resistors* (2004). http://arxiv.org/ftp/cond-mat/papers/0411/0411463.pdf).

Physical, chemical and biological components of nanosystems

There is, for example, the fabrication of a programmable microfluidic device similar to an electronic computer. "The human body so far is the ultimate 'wet computer' –a highly efficient, biomolecule-based information processor that relies on chemical, optical and electrical signals to operate".[4] Researchers are trying to mimic some of the body's approaches to computing. A special field of research is the development of molecular logic gates (see Fig. 2).

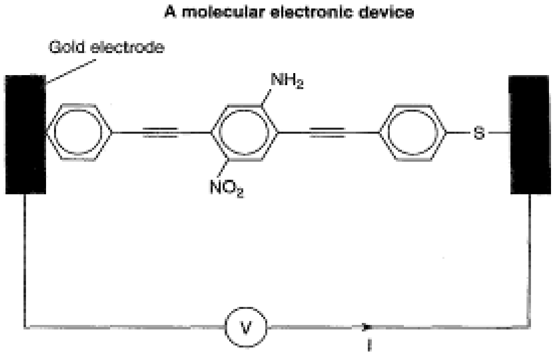

Fig. 2: "Illustration of an electronic switch made of a conducting molecule bonded at each end to gold electrodes. Initially it is non-conducting; however, when the voltage is sufficient to add an electron from the gold electrode to the molecule, it becomes conducting. A further increase makes it non-conducting again with addition of a second electron".[5]

"Already, common logic gates, which are used in conventional silicon circuitry, can also be mimicked at the molecular level. Chemists have reported that a molecular logic gate has the potential for calculation on the nanometer scale, which is unparalleled in silicon-based devices. The general character of the concept of binary logic allows the substitution of electrical signals by chemical and optical signals, which for example opens access to a vast pool of photoactive molecules to be used for the purpose of molecular logic".[6] Such molecular logic gate structures using fluorescence changes have been studied intensively using various inputs: input solutions are routed into "a microfluidic device", which is filled with fluorescent sensor molecules (a fluorescent sensor solution). There the solutions mix and, in certain combinations, switch the fluorescence "output" on or off (Figs. 3-4).

The fluorescence intensity of the pyrazoline derivative **1** is high when the concentration of H+ is low, and vice versa. The fluorescence intensity of the anthracene derivative **2** is high when the concentration of Na+ and/or K+ is high. The emission is low when both concentrations are low. The fluorescence intensity of the anthracene **3** is high only when the concentrations of H+ and Na+ are high. The emission is low in the other three cases. The signal transductions of the molecular switches **1**, **2**, and **3** translate into the truth tables of NOT, OR, and AND gates, respectively, if a positive logic convention is applied to all inputs and outputs (low = 0, high = 1).[7]

These miniaturised chemical analysis systems require only the smallest quantities of reagents. The microfluidic channels are the wires that distribute the information (reagents), while the reaction chambers or mixers are the logical operators. A molecular logic gate in a microfluidic system is based on fluorescent chemosensors by detecting the changes in intensity as a response to various inputs (for example, metal ions). These miniaturised chemical analysis systems are already replacing complex, bulky equipment: Fig. 5.[8]

[5] Ch.P. Pool, Jr., F.J. Owens. *Introduction to Nanotechnology*. Hoboken, New Jersey: John Wiley & Sons, 2003, p. 351. In principle, this electronic switch's mode of functioning doesn't differ from the coherer, an electrical component formerly used to detect radio waves, consisting of a tube containing loosely packed metal particles (filings in Branly's coherer, by Popov´s receiver, or nickel powder by Marconi). The waves caused the particles to cohere, thereby changing the current through the circuit [V. Gorokhov Die Entstehung der Radiotechnik als eine technikwissenschaftliche Disziplin – die Rolle von Ferdinand Braun. In: Wolfschmidt, Gudrun (ed.): *Heinrich Hertz (1857–1894) and the Development of Communication. Proceedings of the Symposium for History of Science*. Hamburg, October 8–12, 2007. 2008, S. 175-201].

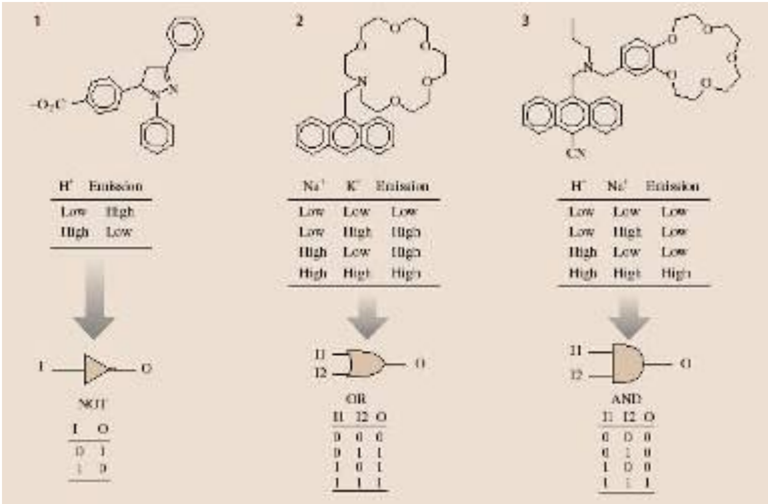

Fig. 3: Molecular Switches and Logic Gates.

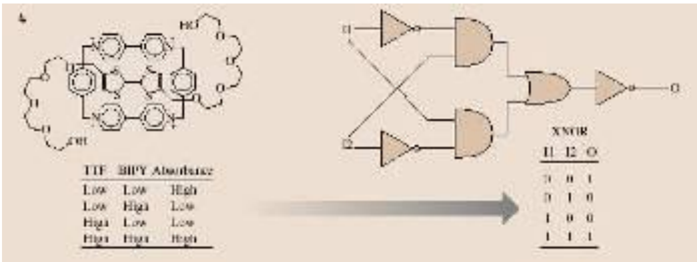

Fig. 4: Combinational Logic at the Molecular Level (The charge-transfer absorbance of the complex 4 is high when the voltage input addressing the tetrathiafulvalene (TTF) unit is low and that stimulating the bipyridinium (BIPY) units is high and vice versa. If a positive logic convention is applied to the TTF input and to the absorbance output (low = 0, high = 1) while a negative logic convention is applied to the BIPY input (low = 0, high = 1), the signal transduction of 4 translates into the truth table of a XNOR circuit).[9]

Biological systems can also be components of electronic circuits derived from large-scale hybrid nanosystems. For example, current flows through a single organic molecule, which permits miniaturizing the electronic device to the single-atom or -molecule scale. A single molecule can be attached to a metallic electrode by using the scanning tunnelling microscope (STM), and can behave electrically like some conventional modern microelectronic components. The sentence, “current flows through a single molecule” actually means that a single electron is transported through an individual molecule. In this case, researchers interpret such molecules as electronic structures or as electronic circuits. These studies have given rise to a new field known as “molecular electronics”. “From the theoretical side, it was clear … that the electronic structure of the individual atoms and molecules plays a crucial role in the electronic transport. Therefore, the theoretical analysis of molecular circuits required a detailed description of the electronic structure of the individual molecules”. Such theories can be different theoretical models of quantum chemistry. But “the first attempts to describe the transport in molecular systems … showed a huge discrepancy with the experimental results, which clearly pointed out the need of further development of these theories”. The concrete theoretical and experimental studies showed that, by fabrication of the metallic electrodes out of Pt, “the catalytic activity of Pt makes the hydrogen molecule an ideal conductor”, inasmuch as the hydrogen molecule can form a very strong molecular coupling between Pt atoms as metallic electrodes. Moreover, these experiments clearly demonstrate that “the transport properties of a molecular contact can not be simply deduced from the properties of the isolated molecules”.[10]

Charge Transport Through Organic Molecules // Nanotechnology – Physics, Chemistry, and Biology of Functional Nanostructures: Results of the first research programme Kompetenznetz “Funktionelle Nanostrukturen” (Competence Network on Functional Nanostructures) / Th. Schimmel et all. (Eds.). Stuttgart: Landesstiftung Baden-Württemberg. – 2008. - P. 59-64.

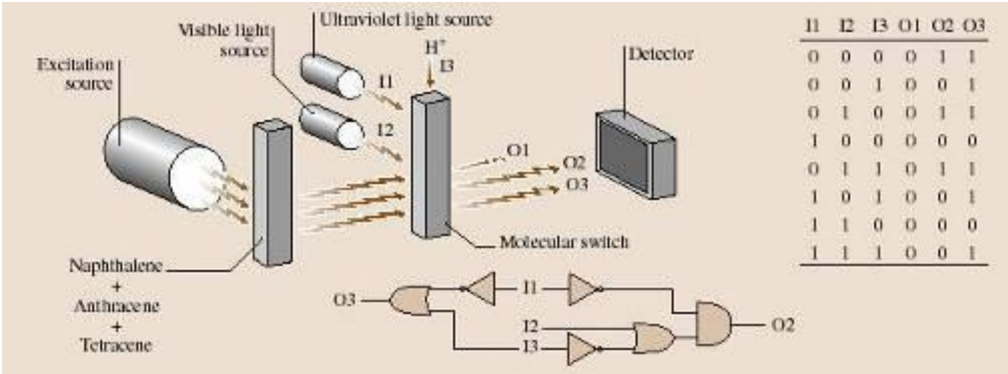

Fig. 5: The excitation source sends three monochromatic light beams (275, 357, and 441 nm) to a quartz cell containing an equimolar acetonitrile solution of naphthalene, anthracene and tetracene. The three fluorophores absorb the exciting beams and reemit at 305, 401, and 544 nm, respectively. The light emitted in the direction perpendicular to the exciting beams passes through another quartz cell containing an acetonitrile solution of the three-state molecular switch shown in Fig. 2.7. Ultraviolet (I1), visible (I2), and H+ (I3) inputs control the interconversion between the three states of the molecular switch. They determine the intensity of the optical outputs reaching the detector and correspond to the naphthalene (O1), anthracene (O2), and tetracene (O3) emissions. The truth table and equivalent combinational logic illustrate the relation between the three inputs and the three outputs. The output O1 is always 0, and it is not influenced by the three inputs. Only two inputs determine the value of O3, while all of them control the output O2.[11]

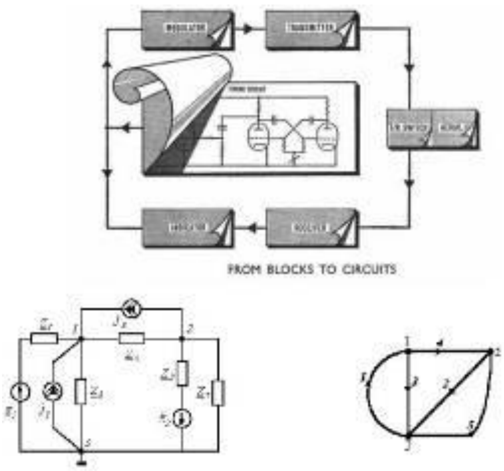

Fig. 6: Schematic block diagram in which each block represents a group of particular circuits (above)[12], equivalent circuits (lower left) and in graph theory (lower right)[13]

From the point of view of radio electronics, it makes no difference how the circuit is constructed (also as a nanostructure). Its blocks and parts can in all cases be represented as the circuits' equivalent to standard electronics components (see Fig. 6).

However one can also construct the circuit on the basis of definite nanosructures (Fig. 7), such as, e.g., a super-heterodyne radio receiver on the nanolevel (see Fig. 8).

16 A. Dudia. Nanofabricated Biohybrid Structures for Controlled Drug Delivery *Proefschrift Universiteit Twente*. Enschede, Gildeprint Drukkerijen B.V., 2007.

An electronic circuit is here only one of the suitable models for theoretical representation of various natural (electrical, chemical, or biological) processes in the *hybrid nanomachine* (similar to the theory of servomechanisms in which the different constructions of the regulator are considered to be equivalent). One is already discussing a further method of constructing "quasi electronic" circuits with the help of chemical (Fig. 2) or biological (Fig. 9) processes.

In nanotechnology, a nanosystem is often defined as a nanocircuit consisting of standard components (see Fig. 10): "Nanotechnological constructions are to reproduce traditional electronic components (switches, diodes, transistors, etc.) on a nanoscale. One main goal of this effort is to open up new dimensions of data processing, namely through the storage of large amounts of data in the smallest possible space … ".[17]

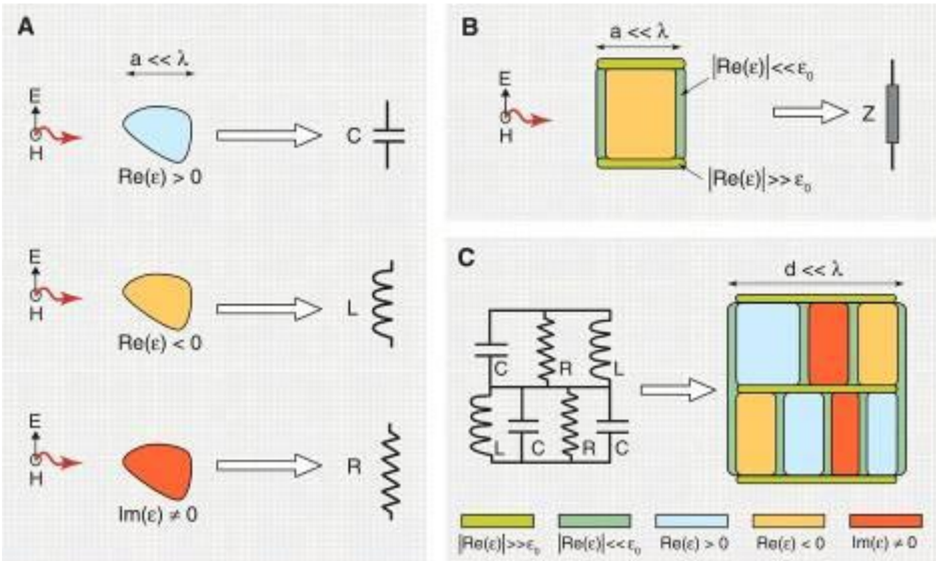

Fig. 10: Subwavelength nanoparticles as lumped nanocircuit elements at optical frequencies, and the collections of such nanoparticles. (**A**) A nanoparticle, with subwavelength size, when illuminated by a monochromatic optical signal, can effectively play the role of a lumped optical circuit element, depending on the permittivity of its material (*2*). (**B**) An optical nanomodule, formed by a material nanoparticle with subwavelength size, covered on its sides by layers of material with a very low real part of relative permittivity and on its two ends by layers of material with a very high real part of relative permittivity. This may perform as an insulated, lumped optical nanoelement with two connecting terminals. (**C**) Illustration of the concept of mn-circuits, several lumped optical nanomodules of (B), arranged next to each other, with a subwavelength dimension. When this mn-circuit is excited by an optical signal, the optical electric fields and displacement currents in these elements are tailored and patterned such that this collection of particles may behave approximately as the circuit shown on the left in a specific frequency band.[18]

In the structure of the nanocircuits we can find many different traditional electronic components ("molecular-scale electronics") realized on the nanolevel with the help of nanotechnology: first, there are electronic elements, second, electronics blocks, and third, large-scale nanosystems, such as, for instance, nanocomputer implemented as "computing at the molecular scale". "Computers of tomorrow could be quite different from what they are today … Computing could become as ubiquitous as electricity … The researchers are also looking at a variety of fabrication processes, from nano-imprint lithography –a kind of production process akin to a traditional printing press–to chemical self-assembly by growing silicon nanowires between electrodes. … Clearly, there's a lot of work to do before nanoscale devices become reality".[19]

NanoTechnoScience as Nano Systems Engineering

So nanotechnology is, at the same time, a field of scientific knowledge and a sphere of engineering activity; in other words –NanoTechnoScience[20]– similar to Systems Engineering as the analysis and design of large-scale, complex, man/machine systems, but now as micro- and nanosystems. "Nanoscience is dealing with functional systems either based on the use of sub-units with specific size-dependent properties or of individual or combined functionalized subunits".[21] Nanosystems engineering is the aggregate of methods of the modelling and design of various artefacts (fabrication of nanomaterials, assembling technology for construction of comprehensive micro- and nanosystems, microprocessing technology for realizing micromachines, etc.). "Microsystems engineering and nanotechnology are two disciplines of miniaturization in science and engineering, which complement each other. Nanotechnology provides access to so far unused, completely novel effects. Microsystems engineering allows for the development of complete systems solutions due to its highly systemic potentials".[22] Nanosystems engineering, as well as macrosystems engineering, includes not only systems design, but also complex research. Design orientation has an influence on the change of priorities in complex research and of the relation to knowledge, not only to "the knowledge about something", but also to knowledge as a means of activity: from the beginning, *the control and restructuring of matter* at the nanoscale is a necessary element of nanoscience.[23] In the nanoexperiment, the scanning tunnelling microscope is not only an instrument of scientific investigation, but also at the same time a facility for fabricating electrically conducting bridges between an electrode, the nanotubes chosen, computer modelling, and design of the various artefacts. "In order to connect carbon nanotubes to each other, they have to be chemically functionalised"; that is to say, some functionally neutral properties of nanotubes are artificially made functionally specific, for example, electroconductive. "The functionalisation is realized with the help of electron beam lithography". Metalorganic molecules can be used as connections. "The adsorbed organometallic molecules can be deposited with the electronic beam at desired locations to form electrically conducting bridges between an electrode and the selected nanotubes". The linker molecule can also be used as a gate insulator as in the field effect transistor. And the transistor is an important product for the electronics industry (see Fig. 11).

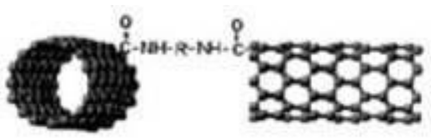

Fig. 11: Schematic drawing of two end-to-side connected nanotubes, where R stands for the linker molecule tripropylentetramin (TPTA) or phenylendiamine (PDA).[24]

In nanotechnoscience, even experimental equipment is a very complicated large-scale system. For its development, design, and fabrication very much time, funds and the work of many scientists and engineers are necessary. The management of such a project is therefore also a complicated systems engineering organisational task. Even alone the coordination of the research groups of physicists and biologists for the investigation and design of the hybrid systems is no simple chore. In addition, the mutual understanding and cooperation of the theoreticians, experimenters, engineering designers, production engineers, and managers who often speak different languages, has to be insured. Technology assessment and risk management, utilisation problems and even nanoethics are also very important. Not only specialists in nanoscience and nanotechnology are needed, therefore, but also generalists with competence for social and methodological reflexion.

So nanotechnology is at the same time a field of scientific knowledge and a sphere of engineering activity; in other words –NanoTechnoScience– similar with Systems Engineering as the analysis and design of complex man/machine systems but now as large-scale micro- and nanosystems.

Abstract

The aim of this paper is to present a short biography of the Spanish mathematician and engineer Tomás Rodríguez Bachiller. He won a chair of mathematics in the Faculty of Sciences during the II Republic and lived well with people of diverse political tendencies. He has been considered as an exiled; however, we shall show that this isn't so. After Spanish Civil War (1936-1939), he was suspect by the Franco Regime at first and a file was made, but this fact had little impact in his life. Many of the activities that he conducted in the Universidad Central *in Madrid and other important scientific institutions, and his important work as translator, will be shown.*

Mathematician and Civil Engineer. Professor of the Faculty of Sciences

Tomás Rodríguez Bachiller (TRB) was born in Hong-Kong on November 10, 1899, where his family lived temporarily because of his father's job: Vice-consul of Spain. His father had two daughters, result of a first marriage, and three sons of his second wife.

He did his first studies in Ayamonte (Huelva). TRB was a brilliant student in the *Instituto Cardenal Cisneros* (High School) in Madrid, getting his graduate's degree in 1916. Thereafter, he started two degree courses: first, Exact Sciences (1916-1922) and two years later, Civil Engineering (1918-1924). "As engineer, he could make a living", as his father said to him.

When he was still an engineering student, in 1923, Einstein visited Spain. TRB became popular among his classmates because made some abstracts of this famous scientist's conferences, which were published in the newspaper *El Debate,* and praised by Einstein himself. This episode would lead to funny stories.

Fig. 1: A photograph of TRB.[1]

During the academic year 1923/24, the Faculty of Sciences gave TRB a grant to stay in France to expand his mathematical knowledge. He was in the College of France and the Sorbonne University, met important mathematicians and received some courses: Borel (on elasticity), Picard (on algebraic curves and surfaces), Drach (on contact transformations), Guichard (on differential geometry and Laplace transformation), Cartan (on fluid mechanics), Hadamard (on differential equations following Poincaré), Lebesgue (on "analisis situs") and Vessiot (on partial differential equations and group theory).

As result of this stay, TRB gave a course on "Analisis Situs" at the Faculty of Sciences in the year 1924/25. This was the first course on topology ever taught in Spain. Millán and Ausejo say [1, p. 273]:

> "siguió investigando en temas de topología y geometría algebraica. En su afán por dar a conocer modernos campos de investigación trabajó en una exposición elemental de la topología y en otra sobre el debate intucionismo-formalismo en el campo de los fundamentos de las matemáticas. En marzo de 1926 solicitó una pensión a la Junta para estudiar con Volterra y Fréchet que al parecer no le fue concedida."

He never left the Faculty of Sciences[2] of Madrid and since 1925, he began his academic life as Assistant in this institution, remaining in it until his retirement in 1969. Since October 1932, he held the vacant chair of *Análisis Matemático 3º* (Differential equations) and on June 29, 1935 TRB got the chair of *Análisis Matemático 4º* (Theory of functions), taking up his post on 29 August. He had entered alone to the competitive examination because the other candidate[3] didn't appear in spite of having been previously accepted to take part in it.

On August 27, 1935 he had defended his doctoral thesis entitled *Axiomática de la dimension*[4] (topology) receiving the highest mark. The jury was composed by José Alvarez Ude (president), Francisco Navarro Borrás (secretary), Pedro Pineda, Honorato de Castro and José Barinaga. This means that TRB wasn't yet a doctor when he won his chair, but had to be so before taking up his post.

On August 23, 1929, TRB had been named Engineer of the Corps of Engineers Geographers after winning a competition. However, he was active about nine years: 1929-1932 and 1949-1955. This job gave stability to his new family, as he had married Mª Pilar Pradilla on May 6, 1926. The priest at the wedding had been the philosopher Xavier Zubiri, and Fernando Lorente de No[5] the wedding witness. The couple had three children: Luis, Agustín and Tomás.

---

[1] We thank to F. A. González Redondo for having provided us with this photograph.

[2] You can know about the different Professors in the Faculty of Sciences of Madrid in [12]. Also, you can see in [10] the photographs of some Professors that were in this institution during the first third of the twentieth century.

[3] This candidate was Ricardo San Juan. That same year, San Juan won the chair of *Analísis Matemático 1º* in Salamanca and the next year, he did it with *Analísis Matemático 2º* in Madrid.

[4] A history of the Spanish Doctorate in the first third of the twentieth century can be seen in [5] and [6].

[5] Fernando Lorente de No became Professor of the Faculty of Sciences. See "Homenaje a los profesores depurados por el franquismo" in *Tribuna Complutense,* 28-11-2006.

Before the Civil War, Rodríguez Bachiller had got a chair in the Faculty of Sciences, belonged to the Corps of Engineers Geographers and taught mathematics in private academies[6]. Besides, he spoke several languages quite well: French, English, German and Italian. This allowed him to read and translate foreign books, not just of mathematics but also literary, philosophical, etc, and to enter into relations with scientists from other countries.

Mathematical activities and intellectual environment until 1936

In August 1922, he joined the *Laboratorio y Seminario Matemático* (*Laboratorio*) of the JAE (*Junta para Ampliación de Estudios*). Since then he took care, close to Lorente de No, of guiding the work of younger students. Ausejo and Hormigón[7] say:

> "The LSM [*Laboratorio y Seminario Matemático*] represents the institutional recognition of research as a necessary and sufficient activity for the social justification of mathematicians."

This institution maintained a close relationship with the Italian mathematicians and TRB was one of those responsible for this,

> "… particularmente con Enriques, Castelnuovo y Severi. En el seno del propio LSM es Rodríguez Bachiller quien cataliza esta actividad, introduciendo el estudio de materias que no se impartían todavía en la Facultad de Ciencias: grupos de sustituciones, funciones de variable compleja, geometría diferencial y topología." [8]

As noted, in 1923 he went to France. Shortly after returning, given his link with the Faculty of Sciences and the *Laboratorio*, Bachiller continued his work as a researcher. He had an intense activity in the Spanish Mathematical Society until 1928 through its journal *Revista Matemática Hispano-Americana*[9], participating in it in different ways: reviewing university publications, writing short obituaries and maintaining a correspondence with European mathematicians. In addition, he published some articles such as *La correspondencia biunívoca de Cantor y el teorema de Netto* (1926), *Conjuntos cerrados no densos* (1926), *Sobre el número de dimensiones de un conjunto* (1927) and *Conferencias del Profesor Terradas* (1927).

In 1923 he had attended to the Ninth Congress of the *Asociación Española para el Progreso de las Ciencias*[10], held in Salamanca, and two years later, to the next, held in Coimbra, with a brilliant participation in this last.

Since 1928 he disappeared from the *Sociedad*, its journal and the *Laboratorio* until 1933. The reason was probably an incident he had with Julio Rey Pastor in a session of the *Sociedad*[11]. In 1933 TRB figured again as member of the Board in which José Mª Plans was the director and José Barinaga, deputy director, they both Professors in Madrid.

He had started to collaborate in other cultural magazines as *La Gaceta Literaria* and *Cruz y Raya*. The first was founded by the fascist E. Giménez Caballero. The participation of TRB in it was not effective but appeared in the first issue as responsible for mathematics. This journal was published in Madrid between 1927 and 1932, when it disappeared for political reasons:

> A principios de 1931 Ernesto Giménez Caballero colaboró con Ramiro Ledesma Ramos en el lanzamiento de *La Conquista del Estado,* y al proclamarse en abril la República, las posiciones políticas de Giménez Caballero y su defensa del fascismo, determinaron que todavía más colaboradores se fuesen olvidando de escribir en *La Gaceta*[12].

In 1933, TRB began to collaborate in the magazine *Cruz y Raya, revista de afirmación y negación*. It was founded by the republican José Bergamín, although this publication was open to collaborators of different political tendencies. TRB published a popular article entitled *El concepto de número de dimensiones de un espacio*. Zubiri, his friend and priest at his wedding, was also an important collaborator in it.

---

6 His family remembers, not clearly, that Bachiller became to give preparatory lessons in the famous Academy Krahe (see [8]) in Madrid. Years later, he had his own one.

7 They think that the *Sociedad Matemática Española* (*Sociedad*) and the *Laboratorio* were key agents in the process of the involvement of Spain in the international mathematical mainstream, interrupted in 1936. See [2].

Fig. 2: *Cruz y Raya*.

As his friend Antonio Rodríguez Huéscar noted in 1980[13], Bachiller was a great friend of the social gatherings and indeed he was one of the members of the circle organized around the *Revista de Occidente*, captained by the philosopher José Ortega y Gasset. Also, Rodríguez Huéscar said:

> "Conocí a don Tomás –así le llamábamos, familiarmente, sus amigos más jóvenes– recién acabada la guerra civil, en su tertulia del café Ibiza (en la plaza del Callao), y desde entonces mantuve con él trato ininterrumpido. Fue Bachiller durante toda su vida hombre de tertulia. Concurrió a la de la *Revista de Occidente,* desde antes de la guerra civil, aunque yo no tuve ocasión de encontrarme entonces con él, pues Ortega se reunía con nosotros, a la sazón sus alumnos, en la sede de la revista, en la Gran Vía, a horas diferentes de las de la tertulia ordinaria de «los mayores»."

Probably, these activities were the reason why the winning factious side linked TRB with the losing side after the Civil War. The truth is that he kept at the time, and in the future, good contacts with colleagues of both political tendencies. In fact, his brother Ángel, philosopher and monk that left the Dominican Order in 1935, would be in prison during the war and suffered an "interior exile" in Spain.

His life during the Franco Dictatorship

After the Spanish Civil War, thousands of people had to emigrate to other countries for fear of repression by Franco, which included about a hundred Professors. Some Spanish mathematicians were repressed by the Franco Regime. In this paper, we highlight two: José Barinaga and Fernando Lorente de No. The first[14] had been member of the jury in Bachiller's competitive examination and his doctoral thesis defence, backing him in both cases. Besides, they had been together in the Interim Board of the journal of the *Sociedad* in 1937. Lorente de No had worked with Bachiller in the *Laboratorio* and the journal of the *Sociedad*, but mainly, they were close friends. Finally, Barinaga was a victim of the Franco Regime, as he was separated of his chair until 1946. Less lucky was Lorente de No, who had to give up the university forever.

Bachiller was also suspect for the Regime. On October 10, 1939, he was opened an administrative record and failed to receive half his salary. Two months later, December 22, he was allowed to be on active, but disqualified for occupying managerial and confidence posts. Therefore, he returned to his chair of *Theory of Functions* without interruption until his retirement, except for some periods in which he was in Puerto Rico. He suffered a similar reprisal in the National Geographic Institute on December 22, 1945 because he still belonged to the Corps of Engineers Geographers. Despite not being able to occupy managerial posts, he did so, as we shall see.

About Bachiller's political views, Glick [9] says:

---

[13] Antonio Rodríguez Huéscar wrote an article in the newspaper *El País* for Bachiller's death, which occurred on July 9, 1980 in Madrid. See [13].

[14] See [3].

> "Rodríguez Bachiller no tomó parte activa en la política, pero ideológicamente fue demócrata de raíz. Me señaló su susto cuando, estando en Berlín en 1936, fue a saludar al rector de la Universidad, el matemático Ludwig Bieberbach, y éste le respondió con el saludo nazi. En 1941, fue a Roma para seguir unos estudios superiores con Francesco Severi. Era un momento oportuno. "Me sacaron los italianos –diría– de un ambiente hondamente antipático" (recordando la fortuna de Lorente de Nó)."

He had an intense activity in the *Sociedad* again. He was member of its Board in 1941 and returned to work to the journal which had been reorganized and now was published by the *Instituto Jorge Juan*[15]. Bachiller proposed in this journal a lot of mathematical problems, did reviews on books of foreign authors and translated several articles about topology and theory of functions.

But he wanted to research in mathematics, so in 1941 he went to the *Istituto Nazionale di Alta Matematica* in Rome, at his expense, after having been refused a financial aid. There, he gave several lectures on recent results on algebraic surfaces and topological manifolds. On his return, he gave several courses on these topics, current at that time, in the *Instituto*. Also, in 1947, after winning a scholarship[16] to go to the USA for five months, Bachiller was working with Zariski in the University of Illinois (Urbana) and with Lefschetz, Artin and Chevalley in Princeton.

Therefore, he played an important role in the *Instituto*. He gave several courses on topology since 1942, and logic and foundations of mathematics since 1951. For example, in the years 1943/44 and 1944/45 he lectured on "Topological Groups", after intervening in the Congress of the *AEPPC*, held in Oporto in 1942. Although the *Instituto* wanted to publish all these lessons, finally it was not done.

But besides, he was deputy director of the *Instituto* since 1946 until 1949, year in which he replaced José Mª Orts in its direction, remaining ten years as director. During this time, he went to several international meetings such as:

1949. París. Conference about algebra and number theory.

1950. Rome. Meeting held because of Severi's retirement.
Annual meeting of the Italian Mathematical Union.
University of Harvard and MIT in Cambridge. International Congress of Mathematicians (ICM).

1952. Rome. First General Assembly of the International Mathematical Union (IMU).
(Bachiller was representing the Spanish mathematicians).

1955. Princeton. Institute for Advanced Studies.

1956. México. Topology conference.

Despite all these activities, he published few research articles due to a deliberate lack of productivity, according to his friend Rodriguez Huéscar. After the Civil War, he just published a research article, in 1942, entitled "Sulle superficie del quarto ordine contenenti una conica" that appeared in an Italian journal[17]. Also, he is the author of other articles, all them published in the journal *Revista Matemática Hispano-Americana*[18]. However, he directed six doctoral theses:

1940. E. Linés (on probability).

1941. F. Botella and Pedro Abellanas (on differential geometry).

1945. F. Gaeta (on algebraic geometry).

1952. J. R. Fuentes (on logic).

1954. B. Rodríguez Salinas (on differential equations).

Besides this intense activity in the *Instituto* and the lectures on theory of functions (in his chair), he also gave other lessons such as *Mecánica celeste* (of Doctorate, during the years 1945/46 and the next) or *Análisis Matemático 5º* (1947-1957). He gave lectures on *Matemáticas generales* in the Selective Course of the Faculty of Sciences and *Matemáticas* in the *Escuela de Estadística*. He also took part in the *Escuela Oficial de Telecomunicaciones* appearing among his courses: *Fundamentos matemáticos de la teoría de la comunicación* and *Geometría de las redes eléctricas* (in collaboration with A.

---

[15] Formerly *Laboratorio*, that belonged to *Consejo Superior de Investigaciones Científicas* (formerly *JAE*). See [11] to know the activities in the *Instituto* during the Spanish Civil War.

[16] Scholarship granted by the *Ministerio de Asuntos Exteriores* (Foreign Office).

[17] *Atti Accad. Italia, Rend. Cl. Sci. Fis. Mat. Natur.* (7) 3, 556–562.

[18] 1941: "Comentarios sobre álgebra y topología", 1, 68–74; 1942: "Sophus Lie", 2, 245–246, "Curso de Topología", 2, 295–297; 1943: "Curso de Topología", 3, 41–51, "David Hilbert" (obituary) 3, 77–81.

González del Valle). Rodríguez Huéscar notes that many students benefited from the high quality and clarity of his teachings[19].

Since already we have indicated, Bachiller had given private lessons in the Academy Krahe. Years later he founded his own academy jointly with J. Abollado Aribau, in which civil engineers received preparatory classes as it can be seen in the following announcement published in the newspaper *ABC*.

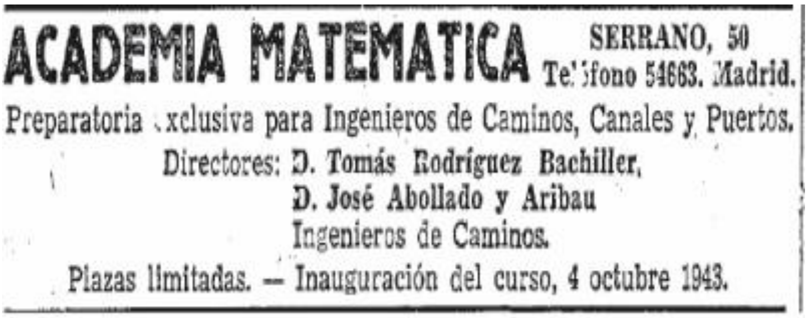

Fig. 3: *ABC*, 23/9/1942.

Because of his knowledge of several languages, the translation of books was an important activity for him, mainly from the mid-50s. So, he translated books such as *Determinantes y matrices* by A. C. Aitken, *Métodos vectoriales aplicados a la geometría diferencial, a la mecánica y a la teoría del potencial* by D. E. Rutherford, *Geometría analítica de tres dimensiones* by W. H. McCrea, *Series infinitas* by J. H. Hyslop, *Lecciones de Geometría Proyectiva* by F. Enriques, and *Lecciones de análisis* by F. Severi, in three volumes. The four first belongs to the British collection *University Mathematical Texts*, whose editors were Aitken and Rutheford. In its Spanish version, this collection, in charge of the publisher Dossat, was directed by TRB.

Fig. 4: Books translated by Bachiller.

He loved travelling, but his travels to Puerto Rico were special for him. His brother Jesús had been born in that country and his mother was buried there after having died in childbirth. In 1954, Bachiller made his first stay in the University of Puerto Rico, in Mayagüez, to teach topology and abstract algebra. This would be done also in successive years. While he stayed in this university, his lessons in Madrid were taught by his former doctoral student J. R. Fuentes. His long absences forced him to leave part of his occupations in Madrid. He left the direction of the *Instituto* and even, in 1959, he was granted a leave of absence for a maximum of ten years (until his retirement) with chair reservation for one[20].

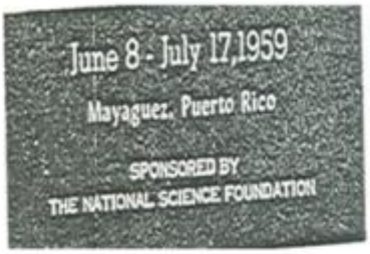
---

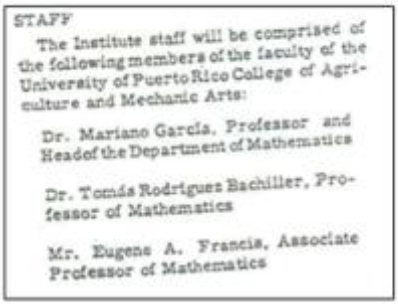
[19] Bachiller was also Professor in the *Escuela de Ingenieros de Caminos* (Civil Engineer School). A. del Campo includes him among "The untypical eccentrics", see [4]. A history of this institution can be seen in [14].

[20] On January 12, 1965, the Rector ordered the opening of a file to Bachiller for not being at work on time.

His taste for social gatherings, practiced before the Spanish Civil War, was able to be continued in Puerto Rico. There, his friend Rodríguez Huéscar noted:

> "Cuando yo me incorporé a la Universidad de Puerto Rico, en enero de 1956, se constituyó allí, con ocasión de mi llegada, y en parte por iniciativa mía -en gran parte, también, por la de Manuel García Pelayo, Gabriel Franco, Alfredo Matilla, Pedro Bravo, entre otros-, otra tertulia, en su mayoría, aunque no con exclusividad, de españoles universitarios, de la que Bachiller -profesor en aquella universidad desde hacía algún tiempo- fue uno de los puntales."





STAFF

The Institute staff will be comprised of the following members of the faculty of the University of Puerto Rico College of Agriculture and Mechanic Arts:

Dr. Mariano Garcia, Professor and Head of the Department of Mathematics

Dr. Tomás Rodriguez Bachiller, Professor of Mathematics

Mr. Eugene A. Francis, Associate Professor of Mathematics

Fig. 5: Professor of Mathematics in Puerto Rico.

These frequent visits to Puerto Rico are the reason why Bachiller has been considered as one more exile, but we have seen that this is not the case. In spite of having a file made by Franco Regime, this had little impact in his professional life. Finally, we have to highlight that he was one of the Spanish mathematicians who most contributed to the importation of modern topology and its introduction into the syllabus of the Degree of Exact Sciences (1954).

FIGHTING ISOLATION: THE MATHEMATICIAN NORBERTO CUESTA DUTARI

José M. PACHECO
Departamento de Matemáticas, Universidad de Las Palmas de Gran Canaria, SPAIN
pacheco@dma.ulpgc.es

Abstract

This presentation describes the struggle against isolation of Norberto Cuesta Dutari (1907-1989) under the Franco regime. Though he was not close to the establishment and could not profit from a number of opportunities for personal and institutional promotion, he achieved a mathematical production of international quality. His creative papers –dating back to 1943– are still cited in fields like Descriptive Set Theory or Decision Theory. His contribution to pure Mathematics was gathered in the book Matemática del Orden *(1958), a common bibliography item of Set Theory.*
The isolation of Cuesta in places like Ávila, Segovia, and Salamanca was for him a lifelong concern, and not only a matter of geographical distances. He often firmly complained about it, but it is difficult to imagine his vital trajectory anywhere else. After his doctorate in 1943 he tried several times to become a University Professor, but only in 1957 could he obtain a chair in Salamanca. He was fifty, lagging some twenty years behind the Civil War generation: Pedro Abellanas (b. 1914) and Francisco Botella (b. 1915), obtained chairs in their late twenties just after it.
Cuesta promoted the Mathematics degree in Salamanca, started in 1971: Even then, isolation won that battle, but the beauty of his Mathematics still remains.

Dramatis persona

In Volume 2, dated 1942, of the *Revista Matemática Hispano-Americana*, we find four papers under the general title *Números Reales Generalizados*[1], written by a certain Norberto Cuesta. The 1943 Volume contained three more papers[2], the second and third ones are the doctoral dissertation of the author, *Teoría decimal de los tipos de orden*, read in 1943. A remarkable theorem, rediscovered by Sierpinski in 1949 and by Chipman in 1960, is stated and proved on the representation

[1] Cuesta N (1942) Números reales generalizados, RMHA (Ser. IV) 2, 5-12, 62-66, 104-109, 218-225.

[2] Cuesta N (1943a) Construcción de un conjunto ordenado denso y no continuo cuyo número ordinal es ω_α, *RMHA* (Ser. IV) 3, 38-40, and Cuesta N (1943b) Teoría decimal de los tipos de orden, *RMHA* (Ser. IV) 3, 186-205, 242-268.

of linearly ordered sets as binary function spaces. The result has important applications in Decision Theory and Econometrics, and is still cited[3]:

> *"Let (X,p) be a totally ordered set and α the first ordinal number such that $|X|=|\alpha|$. Then (X,p) is order-isomorphic with some subset of the lexicographically ordered function space ($\{0,1\}^{\alpha},<^{lex}$)."*

The obvious finite case shows that the representation may not be unique, and the transfinite case proof was obtained by Cuesta in the post-war isolation of Ávila in Central Spain.

Fig. 1: N. Cuesta around 1970.

It is difficult to establish why Cuesta decided to work in the field of Transfinite Numbers, even he was an early discoverer of (the beauty of) Mathematics, at the age of twelve[4]:

> *"Yo recuerdo haberme hecho matemático, al entender los dos teoremas en que se funda la regla del cálculo de la raíz cuadrada. Era el curso 1919-1920"*

Nevertheless, he first studied Chemistry, where he acknowledged the mathematician Guillermo Sáez as an outstanding teacher. Sáez wrote a dissertation on elliptic functions in 1903 and spent the year 1909-1910 in Leipzig studying with Hölder, and possibly Hausdorff, with one of the first JAE[5] grants. Surely, Sáez's lectures influenced the vocation of Cuesta, who had studied high level Mathematics books before obtaining his Chemistry[6] degree.

Then he moved to Saragossa, completing a degree in Mathematics, and after graduation he was hired as an assistant at Granada University. In late 1937 he was sent to a Secondary School in Teruel, but the Republicans conquered the city in December 1937, he was captured and imprisoned in Valencia. Some months later he was released and served in the Republican Army until the war end. This ex-prisoner condition helped him to obtain in 1940 a Secondary School professorate. We have no information on his mathematical activities at Granada, but he must have been busy with them, for he writes[7]:

> *"Yo había frecuentado mucho, desde que salió el 1929, el bellísimo libro de Sierpinski* **Leçons sur les nombres transfinis***"*

Cuesta might have considered Set Theory an affordable topic on an individual basis with some basic books and journals, so he started doing research with his readings of Sierpinski and Hausdorff[8]. Post-war isolation in deep Spain kept him away from the influence networks ruling Academia and the Science Agency CSIC[9]. In any case, he did not have to "ask for a research topic", and he always produced independent work of a very personal and original character.

According to Cuesta, if Mathematics could be set-theoretically described, techniques should exist for building large sets, and tools for counting, ordering, classifying, and naming them. He chose to study Orders and their Names, on which he spent some twenty years between 1941 and the early 1960s, addressing questions like:

1. How to build all linear orderings on arbitrary sets: This is his Thesis, where in addition he compared his method with Hausdorff's lexicographic one.
2. How to name these ordering relationships (the *onomastic* problem), and in particular ordinal numbers. This is still an unsolved problem[10].
3. Generalisation to partial ordering relationships. He achieved it in his only paper in English (or something like it) in 1955.

Spanish historical background behind Cuesta's mathematical work

The biography of a Spaniard living between 1907 and 1989 was marked by three episodes: The Spanish Civil War, WW II, and their consequences. Several viewpoints can be adopted in a biographical approach, but here we will consider the influence of several stresses on Cuesta's mathematical output, focusing on the quality of Mathematics, both in absolute terms and in its relation with the prevailing environmental conditions.

The crucial years are the early post-Civil War ones, 1939-1945, when the Franco regime established an idiosyncratic social organisation in "neutral" Spain while WW II ravaged the world. It was a complex mixture: totalitarianism, *élites* and *parvenus* struggling for favour in Franco's environment, desperate Regime efforts to obtain reconnaissance and forgiveness for earlier connivance with the fascist regimes in Italy and Germany, scarce harvests, poverty. Large numbers of unskilled people fled to South America, but there was also an inner mobility from Central and Southern Spain to the North and the Northeast, where, in spite of the Civil War, industry was still concentrated. Political decisions were made in Madrid, in a centralised way inspired on military schemes: Spain was ruled by a mix of war economy and overreaction against almost any policy practised by the Republic between 1931 and 1939.

Going into Mathematics, we begin with a brief overview of the period 1900-1936, split into two sub-periods roughly separated by WW I. During the first one, mathematical curricula in Spain catered mainly to the preparation of Engineering studies and had little to do with mathematical research: Calculus, but little Mathematical Analysis, Mechanics, some Statistics and a dense part of Classical Geometry inspired in *traités* like Rouché-Comberousse's, used for decades.

Some mathematicians obtained JAE grants during its first existence years. Guillermo Sáez was one of them, but the main role was played by Julio Rey Pastor (1888-1962), who spent nearly two years in Germany before WW I and came back to Spain with a panorama of modern Mathematics he started to implement in a frenetic activity[11].

1. Journals and publishing, I

Dissemination of scientific results before WW II was to a large extent a local affair. Most countries had their own journals[12], where national authors published. Publishing in foreign journals happened on occasion of visits or stages or on request by some editor.

The *Sociedad Matemática Española* (RSM, established 1911) started its own journal, and when Rey Pastor founded the *Laboratorio-Seminario Matemático* (LSM, 1915 and 1918) within the JAE, it had its journals, publishing papers on new topics: Mathematical Physics, Relativity, Nomography, Numerical Mathematics, and on Teaching and Promoting Mathematics. The journals were *Revista Matemática Hispano Americana* (series I and II) and *Matemática Elemental* (series I

---

[8] The so-called *Leipziger Berichte* from 1906-1907. The 1914 text, *Grundzüge der Mengenlehre* was also studied by Cuesta, but he preferred the *Berichte*.

[9] CSIC: *Consejo Superior de Investigaciones Científicas*,The Mathematics Institute was named after the 18th Century Spanish mathematician Jorge Juan.

[10] A partial negative answer presented to the Academy by Cuesta himself is: Arias de Reyna J (1984) El problema onomástico para los ordinales numerables, *Rev. Acad. Ci. Madrid* 78, 201-203.

[11] Although Rey Pastor started his renovation of Spanish Mathematics in the field of Geometry, this discipline, as well as Astronomy, and some others, were not so directly influenced by his ideas.

[12] Prior to the journal of the RSM there were some other attempts in Spain. See Escribano Ródenas *et al.* in these Proceedings.

and II). Among the newer topics, Rey Pastor introduced the study of divergent series and summation processes in 1928-30: his students Sixto Ríos (1913-2008) and Ricardo San Juan (1909-1969) read dissertations on series summation in the early thirties. Ríos abandoned Analysis after the War and switched to Statistics, but San Juan continued studying series and related matters. Rey Pastor also introduced Tauberian theorems in Spain in 1933, as well as ideas of Topology following the Hausdorff style: G_δ and F_δ sets are defined in the 1941-42 lecture notes on Analysis by San Juan, but with no applications.

2. Survival and continuities after the Civil War

After the Civil War all scientific institutions prior to 1939 were overrun by the *Instituto 'Jorge Juan' de Matemáticas*, a section of the CSIC active until 1982. For years the group concentrated around this Institute governed all official mathematical activity: The few available University positions were unattainable for candidates without the '*Jorge Juan*' approval. Francisco Navarro Borrás (1905-1970), who held the chair of Rational Mechanics at Madrid, was CSIC's man in contests for Mathematics positions –both University and Secondary School ones– from the early forties until the 1960s: The Spanish Official Gazette shows he was almost invariably the head of the examining board.

After the war some Spanish mathematicians (*e.g.* Ríos and San Juan) could continue their work on previous research, or even start other lines (*e.g.* Abellanas and Botella) favoured by the Regime with some funding. But the importance of pure Mathematics was small: Autarchy promoted other Sciences –and related Technologies– like some branches of Chemistry and Physics, Pharmacy and applied Physiology. Applied Mathematics only received some boost when aircraft building was given priority: An *Escuela de Aeronáutica* was created and a number of mathematicians taught there for years[13].

Fortunately, in those years doing pure Mathematics was largely an individual affair, and many mathematicians survived as Secondary School teachers or through private lessons, even some did research on topics where interaction with other mathematicians was not an urgent matter: Cuesta is an example.

With the USA-Spain treaty of 1952, Spain entered the UNO, and scientific policy slowly started to converge with the current standards: internationalisation, collaboration, English as the interchange language. This fact, population increase, and faculty ageing eventually contributed to some of these Spanish outlier mathematicians becoming members of the established community.

3. Journals and publishing, II

Publishing in Spain during the post-war years happened in the *Revista Matemática Hispano Americana* (RMHA), series IV –some enthusiasts had kept it alive (series III) during the war in the Republican Zone. For elementary Mathematics there existed *Matemática Elemental*, also refounded in 1941, and changed into *Gaceta Matemática* in 1949. Both were CSIC journals. The *Revista de la Academia de Ciencias* also contained mathematical papers, as before the war. Nevertheless, *Euclides*, a journal mostly dedicated to students preparing examinations for Engineering Schools, appeared in 1941 with a large Mathematical content: It was founded by José Barinaga (1890-1958), expelled from his chair at Madrid, and José Gallego-Díaz (1913-1965), an engineer and mathematician. *Euclides* survived until 1960, and it provides an example showing the existence of something close to a Spanish mathematical community in the post-war years[14]. The *Revista de la Universidad de Madrid* also offered Mathematics in its section *Ciencias*.

In the early forties some Spanish mathematicians had already published in established international journals: *e.g.* Germán Ancochea (1908-1981) in *Annals of Mathematics* and *Journal für die reine und angewandte Mathematik*, San Juan was also a current author in non-Spanish journals like the prestigious *Portugaliae Mathematica*. Abstracts and reviews of the Spanish production were rapidly available in *Zentralblatt für Mathematik* and *Mathematical Reviews*, started in 1940, so the Spanish production on those years, even with the delay imposed by WW II, is well covered. We have not read any unfavourable comment on Cuesta's mathematics, neither in *Mathematical Reviews* nor in *Zentralblatt*.

Mathematics

Cuesta's main result, the systematic construction of all total orderings[15] on any set, was achieved by firmly believing in actual infinities and by a thorough usage of the well-ordering principle and techniques developed by Steinitz in his 1910 paper on Algebraic Field Theory[16].

1. On algorithms, I

Cuesta did not use the word "algorithm", though he was aware of the possibility of *maquinización*, a word of his invention, in many instances. Moreover, he used the adjective *cronológica* to refer to an auxiliary well ordering needed in his theory. The rationale behind his method comes next.

Let A be any set, and let $a \in A$. Now, well-order A in such a way that a be its first element: This defines a sort of time. Figure out that a occupies some position on an ideal infinitely long supporting line. Then a automatically creates two "vacant places": one in its left side, the other on the right one, yielding a pattern: – a –. Let b be the first element in A – $\{a\}$ and use it to occupy one of those places, say the right one. The result is – a – b –: the vacant place at the right is turned into – b –. Note that there is a decision, choice, or branching (right *vs.* left). Proceed by letting the first element c in A – $\{a,b\}$ occupy one of the three vacant places by changing the chosen empty place into the pattern – c –. Repeat the process.

The choice regarding the place to be changed into – *x* – when introducing any *x* yields a decision tree, within which all possible total orderings of the initial set[17] are represented.

Once the process is over, the problem arises of *naming* that order. Indeed, the order itself could be its name, but this would be impractical by two reasons: First, it would violate the *principle of Borges*[18]; second and worse, isomorphic orderings would receive different names. Cuesta wanted to name order types (isomorphism classes), not individual orders. Therefore he criticised a proposal by Arnaud Denjoy for naming denumerable total orderings. For denumerable ordinal numbers, Cuesta devised this procedure:

Let *S* be a denumerable ordinal number and n_S its name, formed with symbols of some finite alphabet. n_S is an ordinal number complying with Borges' principle: type(n_S)<*S*. Exceptionally, the principle may be violated in some cases; because *e.g.* the empty set needs a name, O=n_O. Ordinals *J* such that type(n_J)<*J* are called *ineffable* and may be needed at some stages, but kept to a minimum. They may appear either by occasional enlarging of the initial alphabet or by recurrence on already existent names. Cuesta's method for naming denumerable ordinal numbers with the initial binary alphabet {0,1} is shown here:

Table 1: Naming denumerable ordinals.

Ordinal	Name	Ordinal	Name	Ordinal	Name	Ordinal	Name
o	**o**	**1**	**1**	ω+1	21	ωx2+1	201
		2	**10**	ω+2	210	ωx2+2	2010
		3	11	ω+3	211	ωx2+3	2011
		4	100	ω+4	2100	ωx2+4	20100
		5	101	ω+5	2101	ωx2+5	20101
		…	…	…	…	…	…
		ω	2(new)	ωx2	20	ωx3	200
Class N1				Class N2			

Boldface: ineffable ordinals. (new) = an alphabet extension

2. On algorithms, II: Inversion of the viewpoint and the proof of "the theorem"

In his construction of total orderings, Cuesta freely used the idea of "filling an empty place" with a given pattern in order to create the order relationship. Now, the viewpoint is inverted, starting with a pre-existent order on some set, considering the addition of elements one at a time, and watching things happen:

Let (*M*,<) be a totally ordered set. A *gap* in it is a disjoint pair (*A*,*B*) of subsets of *M* such that *A*<*B* and *A* ∪ *B* = *M* hold: Now, let *p* be some element which will be used to *fill* the gap: a new set (*M* ∪ {*p*},<) is built under the condition that *A*<*p*<*B*. The insertion of *p* creates two new gaps in (*M* ∪ {*p*},<) "descending" from (*A*,*B*), *viz.* (*A* ∪ {*p*},*B*) and (*A*,*B* ∪ {*p*}). If *v* is a name given to (*A*,*B*), then the two descending gaps could be named, respectively *vi* and *vf*, according to whether the new element was added to the initial (*i*) section *A*, or to the final (*f*) one *B*.

Now, start with (*M*,<)=Ø and consider the gap (Ø,Ø), which will be named O. Then, adding further elements will provide a construction of *binary* names like O*iifiiiif...* This procedure yields the proof of the theorem cited in Section 1.

3. The remarkable 1955 result on the Sierpinski triangle

When shortly after WW II English became the standard for scientific communication, the need of publishing in this language soon became a must. With some delay, Cuesta undertook his only paper in English and gave it to print in 1955[19]. It

---

[17] Cuesta N (1958) *Matemática del Orden*, Real Academia de Ciencias, Madrid.

[18] The name comes from J. L. Borges: a King wanted such a detailed map of his kingdom that eventually his geographers presented him a 1:1 reproduction.

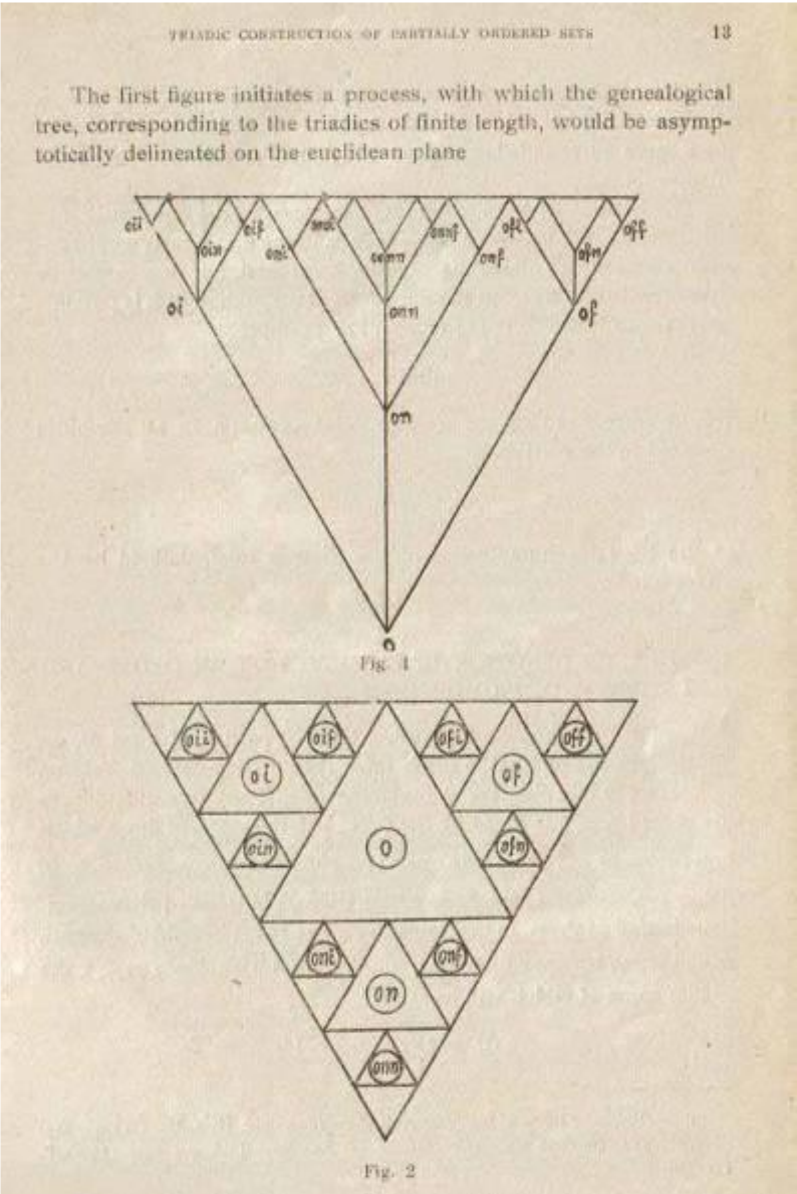
[19] Cuesta N (1955) Triadic construction of partially ordered sets, *Acta Salmanticensia*, Ser. Ciencias, Nueva Serie, Vol. I (4), Universidad de Salamanca.

contains a generalisation of the 1943 algorithm for total orderings to the case of partial orders, by shadowing the binary technique to extend it to *pairs of gaps*:

Let (*M*,<) be a totally ordered set. A *tripartition* of *M* is a triad (*A*,*B*,*C*) of pairwise disjoint subsets of *M* such that *A*<*B*<*C* and *A* ∪ *B* ∪ *C*=*M* hold. One such tripartition may be named τ. Now, let *p* be some element and use it to fill *one* of the two gaps, (*A*,*B*) or (*B*,*C*). The insertion of *p* can be done in any of the forms (*A* ∪ {*p*},*B*,*C*), (*A*,*B* ∪ {*p*},*C*), or (*A*,*B*,*C* ∪ {*p*}). Again a branching process is generated according to the selected choice, and the descending tripartitions will be named, respectively τi, τn and τf, meaning that the new element was added to the initial (*i*) section *A*, to the central one *B* (*n*) or to the final (*f*) one, *C*.

Now, begin with (*M*,<)=Ø and consider the tripartition (Ø,Ø,Ø), named O. Then, adding elements will yield *triadic* names like O*iifnniniiif* ...

This procedure rediscovers the now famous Sierpinski Triangle[20], as shown in the illustrations of Cuesta's original paper: Any denumerable partial order is described by a path joining the centres of ever smaller triangles according to the chosen sequence of *i*'s, *n*'s and *f*'s.



TRIADIC CONSTRUCTION OF PARTIALLY ORDERED SETS 13

The first figure initiates a process, with which the genealogical tree, corresponding to the triadics of finite length, would be asymptotically delineated on the euclidean plane

Fig. 3: Recreation of the Sierpinski Triangle in the 1955 paper.

A few notes on the 1955 paper translation

This section briefly studies some non-mathematical aspects of the 1955 paper. In a most typical way of his, Cuesta and a French friend of his named Antoine O. Broucke wrote the poor home-made translation constituting the paper discussed in the previous section 3. He soon became aware of the bad quality of the language. As in those years he corresponded with Marshall Stone, we know that Stone wrote him that the text *was not in English*. In figure 4 is a letter sent in 1982 by Cuesta to the author of this paper, regarding a possible new English translation of *Triadic Construction*. The task was not performed, basically because at that time the would-be translator hardly understood the Mathematics in it!

Salamanca A de del 1982
Sr. Dn José Pacheco Castelao

Mi querido amigo: Te devuelvo mi viejo artículo que pusimos en un extraño idioma, "alfamiado" de inglés, entre Broucke y "moi"! Es evidente que ganaría bastante escrito en inglés, y encima por quien, como tú, se lo ha estudiado y puede quizá sacarle algunas extensiones útiles. Yo ahora ya no puedo hacer esto último, pues quiero terminar el libro "de la invención e introducción del análisis infinitesimal en España"; sólo terminándolo, servirá para algo la labor informativa que efectué en archivos, en viejas revistas, y viejos libros.

He revisado las reseñas que de ese trabajo conozco. La del Zentralblat 65 (1956) 284-285 de 24 líneas la hizo Kurepa (es croata, casi de mi edad) inventor de las "ordenaciones ramificadas". Tiene un pequeño error, pues dice se pone I < F cuando algún i y algún f de los respectivos verifican i < f. No tiene eso interés; se ha de verificar i < f cualquiera que sean i y f.

La del Math. Revs 17 (1956) 950 de 21 renglones la hizo Baer (Notre Dame Indiana U.S.A) que me resultó bastante [illegible]. No alude al "inglés" del artículo: Stone me dijo que "no era inglés". Desconozco la de las "Referata Mathematicas" de los rusos, que no sé si se [illegible] encontrar en Madrid, o que quizá tenga Emiliano Aparicio en Bilbao.

Quiero advertirte que yo lo incluí, pero con una redacción muy diferente, en mi "Matemática del Orden" (Rev. Acad. Cien. Madrid Tº 52 y 53, 1959)

A mi me satisface más mi Tesis (Rev. Mat Hisp-Am 1943) allí titulada "Teoría decimal de los tipos de orden" si hoy la publicara, la titularía más expresivamente, "Construcción diádica de ordenaciones totales". En realidad los dos trabajos podrían juntarse en uno, y si tienen algo que aún me satisface, es que la construcción es sistemática, introduciendo los elementos uno a uno y haciéndolo de todas las maneras posibles; por eso se obtienen "todas" en un caso y en otro.

Tú harás con él lo que te parezca más oportuno y yo te lo agradeceré en todos los casos posibles.

Un abrazo muy cordial
N Cuesta

Fig. 4: Letter to the author, on the 1955 paper.

The letter shows how aware Cuesta was of the value of his Mathematics: In addition to the reviews in *Mathematical Reviews* and *Zentralblatt*, he humorously refers to his English as *aljamiado*[21]. Most interesting is the reflection on his beloved 1943 thesis, from which the 1955 paper would be a natural by-product, deserving a joint publication. Cuesta's research on ordered sets, including a newer version of the 1955 paper, is gathered in his 1958 book *Matemática del Orden*, cited above.

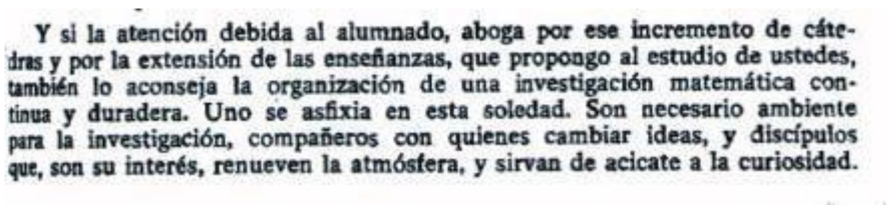
Conclusion: The never-ending isolation

The idea of establishing a Mathematics degree at Salamanca pervaded Cuesta academic life. His personal view, an academia where Mathematics and its teaching would be over any other consideration was an idealised picture of those Göttingen years he much admired and tried to imitate in Seminars he conducted on Monday evenings. For him, scientific policy as an everyday affair meant little, and his Spartan lifestyle could not be easily imposed on other people.

In his 1963 address[22] to the annual meeting of Spanish Mathematicians held at Salamanca, we read his plea for an end of mathematical isolation:

> *"Uno se asfixia en esta soledad. Son necesarios ambiente para la investigación, compañeros con quienes cambiar ideas, renueven la atmósfera, y sirvan de acicate a la curiosidad".*

To understand it, Cuesta was the only Mathematics Professor at Salamanca between 1947 and 1966, with a short interlude in 1955-56. The answer came from the regime evolution in the late 1960s, when, favoured by a series of technocratic Governments, the educational system entered a growing stage in order to cope with an ever larger population and the funding conditions imposed by the World Bank to contribute to the country modernisation, and which led to the 1970 *Ley General de Educación*.



Y si la atención debida al alumnado, aboga por ese incremento de cátedras y por la extensión de las enseñanzas, que propongo al estudio de ustedes, también lo aconseja la organización de una investigación matemática continua y duradera. Uno se asfixia en esta soledad. Son necesario ambiente para la investigación, compañeros con quienes cambiar ideas, y discípulos que, son su interés, renueven la atmósfera, y sirvan de acicate a la curiosidad.

Fig. 5: Final words of the 1963 address.

Without these general environmental conditions, the isolation of Cuesta and the difficulties for his beloved degree in Mathematics would not have been overcome. Indeed many people in other Universities had interests similar to his, but this general picture is a reasonable one.

Table 2: Some new Mathematics studies. Spain, 1963-1971.

Year	University	Promoter	Promoter = School?
1965	Santiago	Vidal	Yes
1967	Seville	Castro	Yes
1970	Valladolid	Martínez-Salas	No
1970	La Laguna	Cascante	No
1971	Salamanca	**Cuesta**	**No**

As he had developed his own idealised picture of actual scientific activities disdaining mundane servitudes like funding struggles, fierce battles around tenures, and other everyday questions, his peculiar ideas on how to do Mathematics crashed with the sudden expansion of the higher educational system after 1970. Cuesta had two students, but only one

[21] *Aljamiado*: Medieval Spanish, written in Arabic characters. Here: the paper was written in Spanish with English words.

SCIENCE AND NATIONAL IDENTITY AFTER 1945

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 734.

SCIENCE AND NATIONAL PRESTIGE: EARLY DUTCH RADIO ASTRONOMY

Astrid ELBERS
Universiteit Leiden, THE NETHERLANDS
elbers@strw.leidenuniv.nl

Abstract

In the first post-war decade, the new field of radio astronomy grew steadily in several countries, including Great Britain, the USA, Australia and the Netherlands. The instruments it used (radio telescopes) required a lot of funding. As radio astronomy originated from wartime radar research, and the first radio astronomers were mainly engineers and physicists trained in radar technology, military patronage and funding were self-evident. There were good reasons to fund radio astronomy during the Cold War. It was supposed to stimulate technological innovations that could be used for military purposes. Moreover, big science projects served national prestige. Especially in the USA, the ties between radio astronomy and the military were very strong throughout the 1940s and 1950s.
In my talk, I will analyse the funding of radio astronomy in the Netherlands. The Dutch situation differed strongly from the other countries. It has not been thoroughly studied yet. The Netherlands was the only country where radio astronomers were formally trained as astronomers, and where the research exclusively served astronomical goals. At first sight, there are no clear links with the military or with possible spin-offs. Nevertheless, the government and the Dutch Organisation for Pure Scientific Research (ZWO) provided a huge amount of their science budget for radio astronomy. The question is why –in an era of post-war recovery– they gave radio astronomy such a priority.

Introduction

After the Second World War, a new field of astronomy came into being, namely radio astronomy. This new field arose worldwide, but in this article I will focus on the situation in the Netherlands. More specifically, I will explain how Dutch radio astronomers succeeded in establishing themselves and how they convinced the Dutch government that this novel, uncertain and expensive scientific field was worth funding. To this end, Dutch radio astronomers concluded strategic alliances with industry and public utilities and they used clever argumentation in emphasising practical spin-offs of their research. Moreover, there was the element of national prestige, to which the Dutch government was especially sensitive. The radio astronomical project could contribute to the national prestige of the country and would stimulate national pride. This was both because of the conspicuous instrumentation as because of the fact that radio astronomy was a field in which the Netherlands could play a pioneering role.

The very beginnings

Already during the *interbellum* period, Dutch astronomers had firmly established their position in the international scientific community. Especially Leiden Observatory of the University of Leiden had become an international centre of astronomy. Under the directorship of Willem de Sitter (1918-1934), the observatory was thoroughly reorganised, which led to an enormous increase in quantity and quality of the output.[1]

However, in the Netherlands the problem remained that due to the cloudy climate, the Dutch were severely hindered in making optical astronomical observations. So for observations, they were largely dependent on other countries. But immediately after the Second World War, new opportunities arose. Grote Reber, an electronic engineer and radio amateur from Chicago, was able to detect radio emission from the Galaxy with a self made radio telescope. His findings were published in the *Astrophysical Journal* of 1940.[2] In the Netherlands, this article of Grote Reber came under the eye of the Leiden astronomer Jan Hendrik Oort (1900-1992). Oort immediately realised that Reber's findings could be extremely important for astronomical research. For the great advantage of radio waves was that they were neither hindered by interstellar dust, nor by earthly clouds. The latter made them –contrary to optical waves– very suitable for 'observation' in the Dutch cloudy climate, even during the day. Moreover, Dutch astronomers had been trying to unravel the structure of the Milky Way for several decades. This was in fact the legacy of the Groningen astronomer Jacobus Cornelius Kapteyn (1851-1922), as Oort explained:

> Consistently pursuing the ideal of revealing the general structure of the entire stellar system, Kapteyn laid the foundations for much of the modern work in this line, thereby initiating essentially all the methods used today.[3]

Unravelling the structure of the Milky Way had proven to be impossible by means of optical waves, as only a small part of the Milky way was observable at optical frequencies. Oort realised that the problem might be solved if a spectral line could be found within the radio spectrum.

In 1944, Utrecht astronomy student Henk van de Hulst confirmed that there was a spectral line of hydrogen at 21 cm, well within the radio spectrum. In the interstellar matter of the Galaxy, there was an abundancy of hydrogen, so the hydrogen line would be strong enough to be detected with a radio telescope.

We can hardly overestimate the importance of the discovery of this 21 cm hydrogen line. As radio astronomer Richard Strom stated: 'This discovery would set the agenda for generations of radio astronomers in Holland and elsewhere.'[4]

In the same year 1944, Oort had a plan ready for the building of a radio telescope. He suggested a telescope with a dish of 25 metres, with a receiver built by Philips, the Dutch electronics company. As soon as the war was over, Oort was appointed professor and director of Leiden Observatory, and he judged it the right time to submit his plan to the Dutch government. But because of the high costs, it was impossible for the government to concede his demands. However, Oort would not give up. But was his project viable in the post-war context? Could science be a priority in a country that was devastated by the war?

Towards a knowledge-based economy

In fact, immediately after the war, there was worldwide a very positive attitude towards science. In the US, Vannevar Bush (the director of the Office of Scientific Research and Development) had just written his famous report *Science. The Endless Frontier*, which would ultimately serve as the basis for the creation of the National Science Foundation (NSF) in 1950.

In his report, Bush strongly emphasised 'pure' or 'basic' research, as this would ultimately lead to useful practical applications. For Bush, scientific progress had proven to be extremely valuable during the Second World War: medical applications –based on former basic research– had reduced the death rate in the Army. Radar –an applied science which had its origin in former research in physics– had played a vital role in defeating the Germans and driving back the Japanese.

The Dutch government too believed that science would play a major role in the country's revival. Therefore, Prime Minister Schermerhorn wanted to create a 'braintrust' of researchers, who would cooperate with the industry and the

government to conduct research in several new fields.[5] This eventually led to the creation of the Dutch national 'Organisation for Pure scientific Research' or ZWO. It was provisionally active from 1947 onwards, but only officially launched in 1950. That war could stimulate the emergence of national scientific organisations was well known. As the first director of ZWO, J.H. Bannier stated:

> Wartime fertility in the family of scientific organizations, as witnessed in the United States during earlier wars by the birth of the National Academy of Sciences and the National Research Council, seems to be a universal phenomenon. In a record number of countries World War II has been responsible for the creation of councils for scientific research and science foundations. Just now the happy event has taken place in the Netherlands.[6]

During the discussions about the founding of ZWO, the report of Vannevar Bush was often referred to in stressing the importance of fundamental research for the prosperity of a nation. It was also argued that the new organisation had to subsidise in the first place projects that were of another scale than those that had always been subsidised by the universities. That meant that the organisation had to support in the first place 'large scale research'[7], especially such initiatives that aimed at *national* organisations for new types of research. Further, an emphasis was placed on fields in which the occupied countries were allegedly seriously behind after the war. These were amongst others mathematical research with very fast calculators and nuclear physics. Therefore, before ZWO as a whole was founded, some smaller initiatives were already taken: in February 1946, the Mathematical Centre (MC) a national foundation for mathematics was created; and in May 1946, a foundation for nuclear physics: the Foundation for Fundamental Research on Matter (FOM). These foundations operated under the umbrella of ZWO. The allocation procedure of these foundations was the same as for individual projects, but the difference was that their projects were executed outside the universities or were a joint undertaking of several universities and had a long term character.

Around 1948, the astronomers from the observatories of Leiden and Utrecht were already cooperating informally for some time and now they considered it a good idea to create an organisation that would efficiently coordinate their research at a national level. Therefore, in the autumn of 1948 Oort and his Utrecht colleague Marcel Minnaert took the initiative to found the research group, named the National Foundation for Radio Astronomy or SRZM ('Stichting Radiostraling van Zon en Melkweg'). It was of vital importance that not only astronomers were members of the SRZM, but also representatives of the industry and public utilities. This made the foundation transcend the level of a merely interuniversity organisation and made it a truly *national* organisation. The board included besides astronomers of the observatories of Leiden and Utrecht also representatives of Philips NatLab (the research laboratory of Philips electronics company), of the PTT (the Dutch Post, Telephone and Telegraph Service), and of the KNMI (the Dutch Royal Meteorological Institute).

Gathering allies

The choice of the radio astronomers to include industry and public utilities in the foundation was strategic in several ways. It was partly related to the fact that the origin of Dutch radio astronomy differed from that in other countries. In other countries (such as Great Britain, Australia...) engineers and physicists with a background in war industry –more specifically in radar– took the initiative in radio astronomy. In the Netherlands, the initiative came from professional astronomers. This had the advantage that these astronomers had well defined research questions in mind and they knew very well how to handle their data. On the other hand, it had the disadvantage that they lacked the technical know-how about the building of their equipment. To find a solution to this problem, the Dutch astronomers concluded alliances with industrial partners and public utilities, which could provide them the necessary technical knowledge.

Especially the relation with the PTT deserves attention. Not only were the astronomers interested in cooperation with the PTT, the PTT was interested in cooperation with the astronomers too. This was because of the ionosphere. Part of the program of the astronomers was to measure the radiation of the Sun. Radio radiation of the Sun had an influence on the ionosphere, which in turn influenced the radio communication of the PTT. Knowledge of these disturbances held the promise of improving the PTT's long-distance communication services.

The cooperation with the PTT was very fruitful for the astronomers. As said before, the first plan Oort handed in for his radio telescope in 1945 was not approved, because it was too expensive. The PTT provided an alternative. At the end of the war, they had salvaged several Würzburg radar reflectors, which had been used by the German forces during the War,

[7] Reinink, H.J. (1947) De voorgestelde regeling van de Organisatie voor Zuiver Wetenschappelijk Onderzoek i.o., in: *De organisatie van het zuiver wetenschappelijk onderzoek in Nederland. Verslag van het Congres gehouden door het Verbond van Wetenschappelijke Onderzoekers te Amsterdam op 22 november 1947* (Leiden: Verbond van Wetenschappelijke Onderzoekers), 3-11 , p. 7.

and the PTT had brought these to their radio transmitting station at Kootwijk. In 1948, they allowed the radio astronomers to use one of these Würzburgs for their research. The PTT gave the astronomers all kinds of research facilities at their Kootwijk site, because they thought they too would benefit from their research. So thanks to the PTT, the astronomers had their first radio telescope in Kootwijk. It was a much smaller and less sensitive one than Oort had originally in mind (with a dish of only 7.5 metres). But nevertheless they could finally start.

And the cooperation with the PTT offered another advantage. The fact that the radio astronomical research could have practical applications in telecommunication guaranteed that the Dutch government would be more inclined to fund the project. Indeed, supporting Dutch industry was a major government concern in these years of post-war reconstruction. When in 1948, Oort wrote a memorandum for ZWO to get funding, Minnaert from Utrecht Observatory advised him to refer to such practical applications:

> In fact, it is a pity that it says nothing about the practical meaning of the research for the radio service: knowledge of the ionosphere and the disturbances in it; probably the possibility to predict these disturbances. I certainly believe that this consideration would be an argument to give us a grant. Maybe you should add a paragraph to the memorandum on a third page.[8]

This may seem somewhat surprising, because ZWO was founded explicitly as an organisation for pure scientific research. In general practical applications and stimulation of the industry were seen to be important, but pursuing such goals was not the task of ZWO. As Minister of Education, Van der Leeuw had explicitly stated: the task of ZWO was to support entirely free and pure research. However, these words could not hide the fact that ZWO clearly privileged projects of which the practical applications were immediately visible, like nuclear physics.

In 1948, SRZM successfully applied for the first time with ZWO for a start up budget. They received for this first year 13,650 guilders for preparatory radio astronomical research.

Radio astronomy and national prestige

The astronomers made sure that their efforts did not go unnoticed, and they kept the press informed. As soon as observations with the Kootwijk started, a lot of articles appeared in Dutch newspapers, in which we clearly read feelings of national pride and the expectancy that the Netherlands could become internationally important in the field of radio astronomy. Besides, it was emphasised that the Dutch industry would be stimulated by the building of the radio telescopes.

Let us for example take a look at an article that appeared in the Dutch newspaper *Het Vrije Volk* (figure 1).

ASTRONOMEN LUISTEREN NAAR DE STERREN

Nederlanders doen radio-waarnemingen in heelal

Binnen tien jaar belangwekkende ontdekkingen verwacht

De sterrenkunde heeft in het fototoestel nog steeds een machtig hulpmiddel. Hier ziet men de draaiing van de aarde — de schijnbare beweging der hemellichamen — in beeld gebracht: op de lang belichte fotografische plaat hebben de sterren streepjes getrokken. Het vlekje in het midden wijst op de aanwezigheid van een komeet.

(Van onze speciale verslaggever)

In Nederland wordt naar de sterren geluisterd! Op de Veluwe, nabij het radiostation Kootwijk, doen Nederlandse sterrenkundigen sinds kort en voorlopig nog met betrekkelijk geringe middelen, waarnemingen in het heelal met behulp van een bijzondere radio-ontvanginstallatie.

Maar er bestaan plannen voor de bouw van een veel grotere luisterpost. Twee Nederlandse industrieën, Werkspoor in Utrecht en Philips in Eindhoven, zullen de ingewikkelde en hoogst moderne apparatuur gaan maken. Als aan deze plannen misschien volgend jaar uitvoering wordt gegeven, zullen de Nederlandse sterrenkundigen de beschikking krijgen over de beste apparatuur, die er tot nu toe bestaat voor het peilen en het aftasten van het heelal langs de weg der radiostraling, — een nieuwe methode, die pas na de oorlog tot ontwikkeling is gekomen.

Fig. 1: Newspaper article in *Het Vrije Volk*, 18 January 1950.

[8] Minnaert to Oort, March 29, 1948, Oort archives, Box 162, Folder B.

Free translation of the Dutch text in the article:

> *Astronomers listen to the stars. The Dutch make radio observations in the universe. Important discoveries are expected within ten years.*
>
> *In the Netherlands people listen to the stars! In the Veluwe, near the radio station of Kootwijk, Dutch astronomers are making observations of the universe, yet with modest resources.*
> *But there are plans for the building of a much bigger instrument. Two Dutch industries, Werkspoor in Utrecht and Philips in Eindhoven, will manufacture this complicated and ultra modern equipment. If the plans could be executed next year, Dutch astronomers will possess the best equipment in the world to make radio observations in the universe.*

This article emphasises that Dutch companies, such as Werkspoor and Philips, would be stimulated by the radio astronomical project. Moreover, the country would be proud to possess the best equipment in the world.

But the radio astronomers did not yet have their telescope with the 25m dish. In 1949, SRZM presented to ZWO a plan for the larger telescope which would be much more sensitive than the one in Kootwijk. The estimated price tag was around f 200,000[9], which was about 17 % of the ZWO-budget for 1950, being f 1,401,293[10]. The plan was not approved at the first application. One of the reasons for this was probably the poor progress of the Kootwijk observations during the first years. The radio astronomers hadn't succeeded in detecting the famous 21cm hydrogen line yet. When, in May 1951, the astronomers finally did succeed in detecting this line, this detection was extensively covered in the media, for example figure 2.

Kootwijk maakt radio-contact met gaswolken in Melkweg

Ontdekking van Nobelprijs-formaat door Nederlandse astronomen

Fig. 2: Newspaper article in *Het Vrije Volk,* 5 July 1951.

Translation of the Dutch text:

> *Kootwijk makes radio contact with gas clouds in the Milky Way. Discovery of Nobel Prize significance by Dutch astronomers.*

This detection of the hydrogen line –and its extensive coverage in the media– certainly furthered the decision of ZWO to finance the building of the large telescope that same year. In their argumentation, the members of the advisory committee of ZWO emphasised –again– the spin-offs of the radio astronomical research. They argued that the building of this radio telescope was not only of importance for the astronomers, but –because of the involvement of several other sectors– it was important for the education of other scientists and technicians too. Besides, the commission was convinced that radio astronomy was a field in which the Netherlands could be internationally at the forefront.[11]

This decision of ZWO to finance the building of the large telescope was, of course, also covered in the media (see figure 3).

Nederland krijgt grootste radiotelescoop ter wereld

Heelal te „zien" ondanks wolken

Fig. 3: Newspaper article in *Het Parool*, 22 October 1951.

Translation of the Dutch text:

The Netherlands get the largest telescope in the world. Universe 'visible' despite clouds.

The telescope was built in the woods of Dwingeloo (Drenthe). It was completed in 1955 and became in fact a symbol of national identity when it was officially inaugurated by the Dutch Queen Juliana herself on 17 April, 1956. For several months, it would be the biggest telescope in the world.

Fig. 4: The Dwingeloo telescope.

Fig. 5: Inauguration by the Dutch Queen Juliana, 17 April 1956.

Conclusion

I hope I have made clear that in the successful establishment of radio astronomy in the Netherlands, national pride and national identity were considerations that did matter.

A helpful circumstance was that after and because of the Second World War, there was an increase in national awareness. The country had to be rebuilt and there was a strong belief that science would play a major role in this recovery. Therefore a national organisation for pure scientific research, ZWO, was created. ZWO favoured projects that aimed at a national organisation of science. The Dutch astronomers embodied this goal by creating the SRZM (National Foundation for radio astronomy), in which Dutch scientists, Dutch industry and Dutch public utilities were represented.

The plan of the radio astronomers to build a radio telescope with a dish of 25 metres, which would be the largest one in the world, aroused feelings of national pride, both displayed in and stimulated by the extensive coverage in the media.

The Dutch government and the country were really looking forward to huge discoveries that would be made in a field in which the Netherlands would be internationally at the forefront.

NUCLEAR PHYSICS AFTER WW II

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 742.

THE 'ATOMS FOR PEACE' PROGRAM PAVES THE WAY: TURKEY'S FIRST EXPERIENCE WITH A NUCLEAR RESEARCH REACTOR

Kaan ATA
Department of History of Science, Istanbul University, TURKEY
kaan_ata@yahoo.com

Abstract

Turkey joined the Atoms for Peace program which aimed to use nuclear energy for peaceful purposes in 1955. It was the first country signing an agreement with the USA within the frame of the program. As part of the program, Turkey would establish a nuclear research reactor and the USA would provide the required knowledge, training and fission products to build and activate the reactor. The USA would also provide research facilities in American training centres to train Turkish scientists who will study nuclear energy.

In this context, an Atomic Energy Commission (AEC) was established affiliated to the Prime Ministry of the Turkish Republic in 1956. The Commission was assigned to carry on all nuclear activities at national level and to provide coordination at international level. Within the framework of the AEC's 'atomic reactor' project, a reactor of 1 MW named TR-1 was installed in agreement with the American Machine Foundry between the years of 1959-1962. Çekmece Nuclear Research and Training Center (ÇNRTC), which embodied this reactor, started the production of radioisotopes to be used in industry, agriculture, medicine and scientific researches in 1962. To meet the need for radioisotopes, a second reactor of 5 MW named TR-2 was installed in the same building and pool in 1984.

This paper will deal with the following questions by exploring the role and the effect of ÇNRTC in the field of institutionalization of nuclear studies in Turkey: ÇNRTC has worked for meeting Turkey's need for radioisotopes. Besides fulfilling this task, to what degree was ÇNRTC effective in researches and training activities in the nuclear field? Did ÇNRTC contribute to production of nuclear technology? Did it realize effective collaborations with national and international institutions? To what extent did ÇNRTC provide the infrastructure facilities for researches that have been done in the universities? What was the role of ÇNRTC in training researchers and experts in the field of nuclear physics?

As it is known, in 1953, Eisenhower, president of the USA, announced to all the countries of the world, a program that would promote nuclear power for peaceful purposes rather than armament. This is the 'Atoms for Peace' program. Within the scope of the program, the USA would share its knowledge on nuclear power with the allied states under mutual agreements. The Turkish government approached the call and the two allied states entered in a mutual collaboration agreement within the scope of the program on 10th June 1955. The text of the agreement and its appendices were accepted by the Turkish Grand National Assembly on 14th December 1956. According to this agreement composed of ten articles, nuclear power would only be used in the civil area.

The first article of the agreement stipulates information exchange between the two states in the following issues:

- design of research reactors, construction and operation of the same; using those reactors only in research, education and medical treatment,
- health and security issues with regard to operating and using research reactors,
- the use of radioactive isotopes in physical and biological researches, medical treatment, agriculture and industry.

In the present study, the establishment and institutionalization process of the 'Çekmece Nuclear Research and Training Center' (ÇNAEM) will be under focus. This is the first nuclear centre established in Turkey within the scope of this agreement. Our examination will cover its activities in the fields of research and education during its first 20 years. Considering the expectations in its establishment and its present-day situation, the impact of ÇNAEM in the field of nuclear research in Turkey shall be discussed. The organization of ÇNAEM, its activities, its nuclear research reactors and the radioisotope produced in ÇNAEM shall be dealt respectively.

The first nuclear research reactor in Istanbul

Fig. 1: ÇNAEM-Istanbul Küçük Çekmece.

The Turkish government started preparations immediately after the agreement was signed with the USA for establishing a nuclear research centre and providing its scientific and technical infrastructure, and to train the required human power. In 1956, a joint committee of eight members including academicians from Istanbul University and Istanbul Technical University was set upon the request of the government. This committee started working for the establishment of a nuclear reactor on the bank of the Lake Küçük Çekmece, located west of Istanbul. The "Law for the Establishment of Nuclear Power" (No. 6821) enacted in the same year stipulated the establishment of a 'Nuclear Power Commission' associated to the Prime Ministry in Ankara. In 1958, the committee in Istanbul was abolished and all the activities on nuclear power were entrusted to the commission established in Ankara. This Commission consisted of specialists from the public institutions related to mining, bureaucrats of the Ministry of Foreign Affairs and the Prime Ministry, as well as physicists, geologists, chemists, doctors and mining engineers working at the universities in Istanbul and Ankara. This commission took over the nuclear reactor project prepared by the Istanbul committee and gave priority to its realization.

The Nuclear Power Commission decided in 1958 that an atom reactor of pool type with 1 MW power would be set up in Istanbul, in the place previously determined. The building to house the reactor and the other constructions were started in 1959 and completed in 1962. The design and setting up of the reactor was realized by the 'American Machine and Foundry' company. The radioisotopes to be used in the researches were supplied by the USA. The reactor reached its first criticality on 6th January 1962, and started operation on 27th May, 1962.

The organization and the activities of ÇNAEM

ÇNAEM was directed by a manager assigned by the Nuclear Power Commission. The first organization in its early years became restructured and the centre was later composed of the following sections:

1. Research and education

2. Technical services
3. Administrative services

The research and education section was composed of the departments of physics, chemistry, radiobiology and nuclear engineering. The technical services section was composed of the departments dealing with the running and the control of the reactor, the production of the radioisotopes, and departments of electronics, health physics and technical service.

The physics department was mainly composed of research groups in the fields of nucleus physics, plasma physics and solid state physics. The chemistry department had groups in the fields of radiation chemistry, radio activation analysis and analytical chemistry. In the nuclear engineering department researches were conducted on reactor physics, reactor technology, and reactor security. And in the radiobiology department, studies in the fields of cell biology, radioecology and plant physiology were performed.

The technical services section was responsible of the reactor's running and maintenance. Furthermore, it was in charge of assisting research and educational activities. The electronics department was entrusted with the production of measuring devices, and control of measuring operations. The radioisotope department was responsible for the production of qualified radioisotopes to be used in the fields of nuclear medicine, industry and research.

The first nuclear reactor of ÇNAEM: The TR-1

The first reactor of ÇNAEM was named TR-1. It was a pool type research reactor with a power of 1 MW. It was activated in 1962 as stated above. The core (heart) of the reactor was located in the smaller section of the pool of 8.70 meters deep and having 450 cubic meters of water. The wall made of barite concrete was 1.75 m thick. The fuel for the reactor was U-235 enriched. Water was used as inhibitor and cooler and graphite was used as reflector.

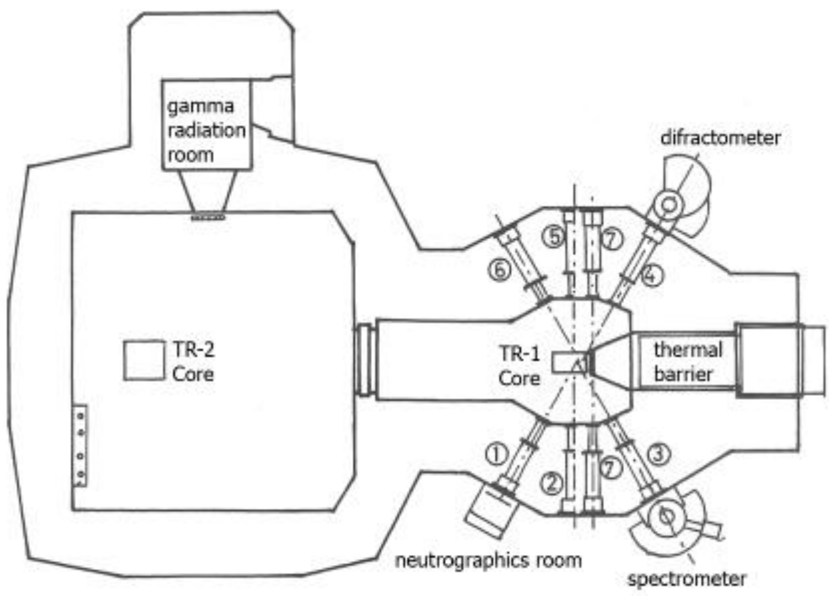

Fig. 2: Plan view of the reactor.

Components of the reactor such as neutrographics room, spectrometer, germanium detector, difractometer and x-ray cameras were used for research and radiation purposes.

The TR-1 reactor, besides producing radioisotopes, was used for research and education in the fields of physics, chemistry and nuclear engineering. The nucleus physics research group studied the structure of nuclei and tested various atomic models through experiments. The plasma group developed new experimental methods in order to measure plasma sizes. For this purpose, a laser laboratory was set up. The reason for focusing on plasma physics was due to the insufficient budget for conducting large size thermonuclear fusion experiments and the lack of trained personnel. Researchers in solid state physics analyzed crystal structures and the interaction of the crystal neutrons. The reactor also was used for researches on radiation chemistry and radiobiology.

Projecting and establishing the second reactor: The TR-2

The setting of a new reactor of 5 MW was envisaged in order to enlarge the scope of applications and increase radioisotope production. A team of four members affiliated to the ÇNAEM were sent to Grenoble Nuclear Research Centre in 1974 and started joint work with French experts. The basic reason for preferring collaboration with a foreign centre in the new reactor project was the need to obtain data to perform neutron and thermo-hydraulic calculations as well as sophisticated computer programs to process these data. The nuclear centre at Grenoble was chosen as the foreign partner because it had a reactor (MELUSINE) similar to the one to be set in Istanbul. The facility provided by the mentioned centre in terms of data transfer to Turkey was another factor for opting to work with Grenoble.

Work in Grenoble lasted for 8 months during which reports, technical specifications and technical drawings were prepared. Besides, the technical details of the new reactor were given in the preliminary project; conditions for repair and fuel renewal of the old reactor (TR-1) were also included. The first reactor was planned to be used only for research after the new reactor became available. Since the new reactor would be set in the building of the old one, the cost of the project would be 50% less. The motto of the Turkish team which prepared the project in cooperation with the French was "do-it-yourself reactor". This project was deemed to be a significant step for the progress of reactor and nuclear technology in Turkey.

TR-1 was stopped on 19th September 1977. In the same year the construction of the new reactor named TR-2 started in the larger section of the pool. 'Belgonuclear', the Belgian company who had secured the tender, completed the construction of the reactor on 10th December 1981. The TR-2 reactor, which was mainly set up to increase and diversify the radioisotope production, was used for the training of the operators. These would be employed in the nuclear power plants to be established in the future for electric power production.

The fuel of the new reactor was enriched U-235. The TR-2, which started to run with full capacity in 1984, was stopped in 1995 to control the earthquake resistance of the reactor building. It has been operated rarely since 2002, and with a power of less than 300 KW.

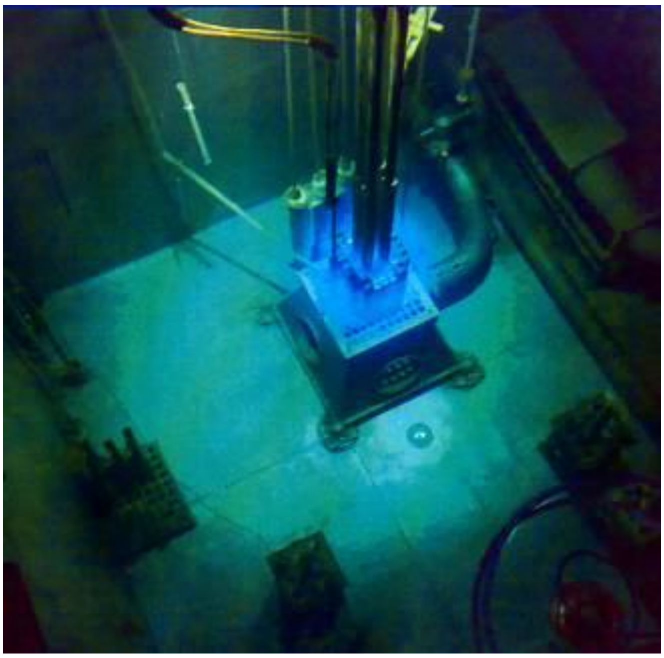

Fig. 3: TR-2 research reactor.

Radioisotope production in ÇNAEM

ÇNAEM, which started producing radioisotope in 1963, was producing 7 different radioisotopes in 1966 and 15 different radioisotopes in 1975:

Table 1: Radioisotopes produced in 1966 (left) and in 1975 (right) using TR-1.

Au-198
Ca-45
Cr-51
Ir-192
Na-24
P-32
Zn-65

Ag-111	Mo-99
Au-198	Na-24
Br-82	P-32
Cr-51	S-35
Cu-64	Sb-124
Ir-192	Tc-99
La-140	Y-90
	Zn-65

Radioisotopes produced were sent to the research centres at universities, hospitals and agricultural centres in Turkey.

Table 2: ÇNAEM radioisotope production from 1971 to 1975.

	1971	**1972**	**1973**	**1974**	**1975**
Nuclear Medicine	89,896	147,335	171,402	178,481	230,154
Industry	22,964	17,400	25,000	30,800	13,600
Research and Training	4,716	0,394	0,305	0,180	0,094
Total	117,576	165,129	196,707	209,461	243,848

As it may be seen in the table, despite the decrease in the field of research, the requirement of radioisotopes in the fields of medicine, agriculture and industry have gradually increased: while the total production of radioisotopes in 1971 was approximately 117 Ci, it became 243 Ci in 1975. The decrease of the demand in the field of research and education, which had already been low, may be caused by the deductions made in the budgets of universities as a result of economic problems.

TR-2 reactor, which began to run in 1981, started its production in 1984 following a control period of 3 years, contributing to meet the deficit of radioisotopes of Turkey. The radioisotopes produced were those having a half-life of a few hours, i.e. with short half-lives.

Following the establishment of ÇNAEM in Istanbul in 1962, attempts of establishing nuclear research centres in Ankara started as well. The "Ankara Nuclear Research and Education Centre" opened in 1967. This was followed by the opening of some nuclear units in the fields of medicine, agriculture and stockbreeding in various state institutions. However, there were no nuclear reactors in these units. The initiatives to set a second reactor in ÇNAEM were concurrent with the construction of a reactor in Istanbul Technical University in 1975. The reactor of the university was named TRIGA Mark-II, and activated on 11th March 1979. This reactor with a power of 250 KW was used for research.

* * *

ÇNAEM was the first nuclear centre in Turkey aiming both research and training manpower. The centre, as well as providing training on the running, control and security of the reactors, offered courses to university students in summer terms.

In addition to the technical work including the production of radioisotopes; manufacturing, maintenance and calibration of the radiation measuring tools, it organized activities to inform the Turkish public about the benefits and damages of nuclear power and radiation. Through the public courses, conferences and publications, ÇNAEM contributed to create awareness in society regarding nuclear power and radiation.

ÇNAEM was in collaboration with national and international organizations from its early foundation: the Nuclear Power Institute (Istanbul Technical University), the Institute of Nuclear Physics Institute (Istanbul University, Faculty of Science), the Faculty of Medicine (Istanbul University), The faculties of Science and Medicine (Ankara University), the

Faculty of Science (Middle East Technical University), the Faculty of Science (Ege University), and the USA Brookhaven National Laboratory.

The studies and researches conducted in ÇNAEM were published annually. Beside these 'activity and progress reports,' researches were published as monographs or in various scientific journals in Turkey or abroad.

The examination of its publications from 1962 up to the present date shows that:

- The top level was achieved in 1972-1973 in terms of the number of publications.
- After the cease of TR-1 reactor in 1977, there is a striking decrease in the publications and reports in foreign languages: From 1977 to 1981, a decrease is observed in Turkish publications as well. There was no publication in 1980 in foreign language and only one report in Turkish.
- As a result of activation of TR-2, an increase was seen after 1981 in the number of publications. Although a significant decrease was seen in the period when TR-2 was in operation (1981-95) Turkish publications continued when compared to the past.

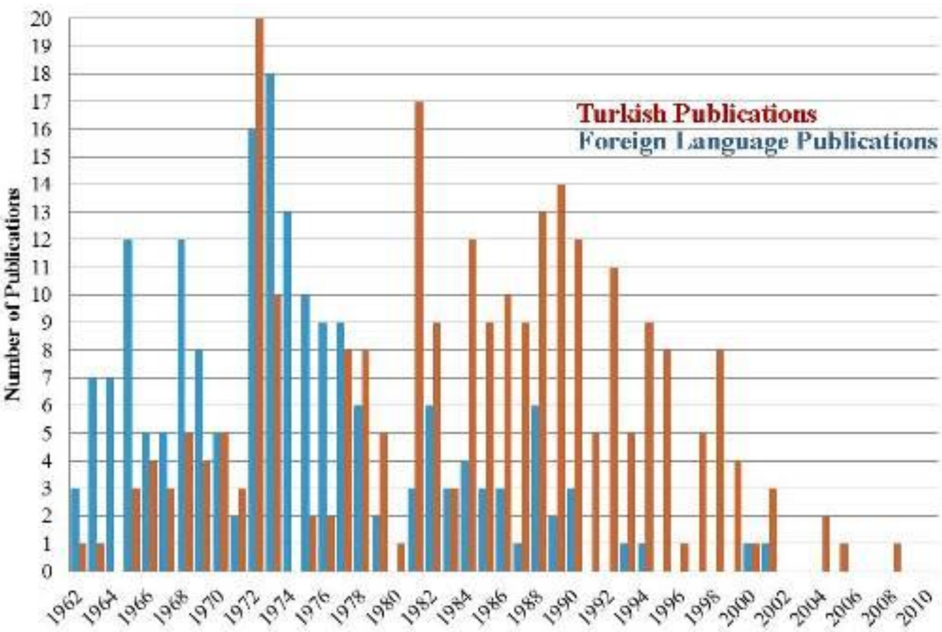

Fig. 4: ÇNAEM publications (1962-2010).

In 1982, together with the issuing of the 'Nuclear Power Law', the Nuclear Power Commission was transformed into the "Nuclear Power Institution of Turkey". This meant a new model in administration, organization and restructuring for nuclear power in Turkey. ÇNAEM was influenced by this reform and underwent new restructuring as well.

The cease of TR-1 after 15 years of functioning led to a decrease in scientific publications and research activities. In addition to this decrease, the setting up of the second reactor TR-2 to produce radioisotopes made impossible the conduct of many experiments that were performed previously in TR-1. TRIGA Mark-II, set up in 1979 in Istanbul Technical University for experimental purposes, seems to compensate experimental deficiency in ÇNAEM.

After joining the 'Atoms for Peace' program, Turkey planned to use nuclear energy in electric power production. The establishment of research and education centres regarding nuclear power was included in the 'First Five Year Progress Plan' (1963-1967). During the preparations of the 'Second Five Year Progress Plan' (1967-1972), the issue was also brought into the agenda but it was postponed until the next development plan period.

Although there have been several attempts to establish a nuclear power plant in Turkey up to date, no energy reactor could be established. ÇNAEM conducted studies and prepared reports on this issue. It provided courses to train experts, and expanded the means of infrastructure. However, there was no opportunity to bring those efforts into action. ÇNAEM, which failed to offer the universities the infrastructure they needed for experimental research, has currently become an institution serving in technical fields such as the production of radioisotopes, the measuring of radioactivity in various fields and the manufacture of radioactivity measuring instruments.

Abstract

The first entry of Spain in CERN was in 1961. At that time, Spain was a dictatorship that started recovering economically from Spanish Civil War (1936-1939) consequences, which devastated the country.
There was only an experimental group in Nuclear and Elementary Particle Physics. It was directed by Professor Joaquín Catalá de Alemany in Valencia. It started their activities in 1950 using the photographic emulsion technique. They established in few time a solid network with the main laboratories and Universities of Europe. The group institutionalized partially in 1958 with the creation of the Centro de Física Fotocorpuscular *in Valencia, funded mainly by the* Junta de Energía Nuclear, *whereas there wasn't a group in this discipline at the rest of Spain. First it was created in Madrid in* Junta de Energía Nuclear *in 1964.*
The entry of Spain in CERN during francoism has been considered as a political issue more than a scientific one. Spain regime suffered from international political isolation until the half fifties. It was easier to participate in that kind of organizations than in other purely political ones. However, we can't forget the existence of this centre in Valencia, though its role was peripheral in the Spanish scientific agenda.
This paper tries to answer four questions. Which role did Valencia's centre play in Spanish CERN entry? What consequences did such entry have in research: staff growth, research lines, travels and stays abroad, collaborations, publications, funding? What relation did the centre have with Spanish Administration? And with Junta de Energía Nuclear*'s group?*
For answering these questions we have looked into CERN Archives among other sources. We must remember

This work in progress is part of the Ph.D. work by one of us (A. Ceba) on the origins and constitution of Experimental Nuclear and Particle Physics in Spain, directed by V. Navarro and J. Velasco. More details on the origins of Catalá's group in: V. Navarro, J. Velasco, J. Domenech, "La creación de una nueva disciplina científica en España: la física nuclear y de partículas" *Cronos*, 7 (1), 61-86 (2004); "The birth of particle physics in Spain" *Minerva*, 43 (2), 183-196 (2005).

that Spain abandoned CERN in 1969, and it didn't return until 1983. Nevertheless, this abandonment would be an issue in another paper.

Introduction

Spain entered CERN in 1961 under General Franco's dictatorship. It had started recovering from the Civil War (1936-1939) that devastated the country.

The main objective of this paper is to study the background of Spain's entry and its consequences from the perspective of the centre created by Professor Joaquín Catalá in Valencia in 1950, the *Institute of Corpuscular Physics* (IFIC).

The development of Spanish Physics after the Civil War is not yet well known. In a broad sense this is a case study about scientific development in non democratic regimes and the integration of Spanish physics in European projects. The references to Spain in the official history of CERN are minimal[2], and the scarce references in the Spanish bibliography are based in personal reminiscences and JEN documentation[3]. The difficulties of the study of Spanish contemporary science are the bad conservation of sources and/or its wide dispersion. For example the correspondence of professor Catalá is lost. This paper attempts to fill this historiographical vacuum.

Some of the questions which arise in this paper are the influence of the political, economical and scientific situation of Spain in the development of Catalá's group; the interest by the members of IFIC in CERN; the consequences of the entry for their research; and the relations with JEN.

IFIC until 1961

Joaquín Catalá, born in 1911 in Manresa (Barcelona), was professor of Theoretical and Experimental Physics in Valencia from 1945.

In 1949 he obtained a one-year-grant from the Spanish National Research Council (CSIC) to study at the University of Bristol within Sir Neville Mott's group of Solid State Physics. Finding it too theoretically inclined, he moved to Cecil Powell's group, which studied nuclei and particles with the photographic emulsion technique, thanks to his friendship with W.Gibson[4]. Next year Powell won the Nobel Prize in Physics for applying the photographic method and the discovery of mesons in Cosmic Radiation.

Back at the University of Valencia in 1950, he gave the Academic Opening Lecture entitled "The Photographic Technique in Nuclear Physics and Cosmic Radiation", where he complained about the small role given to physics in Spain and justified the creation of his group with scientific, economical and social arguments (for instance, the pacific applications of Nuclear Physics).

The technique allowed laboratories with scarce resources to be competitive with the big American centres which employed huge machines and sophisticated electronic counters, underlining that successes did not always have to be proportional to material resources[5], emphasizing the international character of research in Nuclear Physics[6].

Kokowski (ed.) *The Global and the Local: The History of Science and the Cultural Integration of Europe*. Proceedings of the 2nd ICESHS (Cracow, Poland, September 6–9, 2006), pp. 480-486.

[6] "Hemos iniciado en nuestra Facultad modestas investigaciones nucleares, aportando de este modo nuestro pequeño esfuerzo a una obra de mayor envergadura". Catalá (1951), *Op. Cit*, p. XVI.

The use of the photographic technique was an ideal tool for a poor and isolated country like Spain, where a basic food ration book existed until 1952. The Civil War caused a rupture in Spanish science. Some teachers went into exile and others were purged[7]. The institutional structure was modified, focusing in applied research in coherence with the autarchic economical policy. In 1939 the Spanish National Research Council (CSIC) was created as a multidisciplinary research public body, and in 1951 the Nuclear Energy Board (JEN) for developing nuclear energy activities[8].

In September 1950 Catalá set up his group with four Ph.D. students (three chemists, one physicist). Infrastructure was scarce: one microscope, a few emulsion plates, and some photographic materials, in a small room at the Faculty of Sciences. In 1958 they were 19 people, with 5 microscopes available, one of them a high precision Koritska[9].

The main research lines were related to emulsion techniques: nuclear reactions and spectroscopy, pion interactions with emulsion nuclei or techniques related to emulsion chemistry.

Soon it was the most productive group in the Spanish journal *Anales de Física*, quickly obtaining recognition from his colleagues. Catalá was awarded the first Medal of the Royal Society of Physics and Chemistry (RSEFQ) in 1958 for his labour of research, organization and direction[10].

However the research programme presented in the Opening Lecture of 1951 could not be fully carried out. In particular research into Cosmic Radiation, a field where strange particles were a hot topic of the day.

Catalá tried unsuccessfully to join European collaborations inspired by Powell and Occhialini, which made three balloon launches from 1952 to 1954 in Italy to study Cosmic Radiation[11]. It has been said that Cosmic Radiation was the Nuclear Physics of poor countries, but according to Catalá Spain could not even contribute to the launching of balloons[12]. Emulsions analyzed in Valencia were obtained at accelerators and facilitated by foreign laboratories[13].

Cosmic Radiation was unable to compete with the Synchrotrons at Berkeley (Bevatron) and Brookhaven (Cosmotron)[14]. The Italian, Belgian and English groups sent their plates to Berkeley. Catalá tried in vain to collaborate through those groups with the Californian synchrotron[15]. He complained about the great delay of Spain with respect to other countries in a moment where there were a lot of discoveries to be made[16].

Spain and CERN[17]

Around 1950 Nuclear and Particle physics started to be dominated by accelerators. In June 1950 Isidor Rabi presented a resolution in the General Assembly of UNESCO to built European laboratories, one of them for basic nuclear research promoted mainly by physicists Pierre Auger and Edoardo Amaldi.

After difficult negotiations the *Conseil Européen pour la Recherche Nucléaire* was created 15th February 1952. In April it was agreed to design a protosynchrotron of strong focusing of about 30 GeV energy. In 1954 the provisional council was dissolved and the organization renamed European Organization for Nuclear Research (CERN).

CERN's foundation has been considered both a scientific and a political project, a model for European cooperation. It was a complex process because the actors involved (scientists, science administrators or governments) had different interests[18].

Spain did not participate in the negotiations for the creation of CERN[19]. The initiative was from UNESCO, and Spain did not enter into this organisation until 19 November 1952. The first known reference of an interest is a report by José Maria Otero Navascués (JEN director general) after the First Conference of Pacific Uses of Atomic Energy (Geneva, August 1955), where he considered it necessary to enter into CERN. Catalá, member of the Spanish delegation[20], was coordinator of translation into Spanish for the Conference's Proceedings[21].

In the fifties Spain had progressively improved its international relations. In 1953 it signed the Agreement of Defence and Cooperation with the United States that would facilitate Spain's entry into the United Nations in December 1955. President Eisenhower visited Spain on December 23th 1959.

When the CERN council was consulted in 1956 about Spain and Austria membership, no objection was made[22]. The main difficulty was the financial contribution (letter by CERN director general C.J. Bakker to L. Garcia Llera, Spanish Delegate at International Organisations in Geneva), considered too high by Spain. Bakker answered that the method used for calculating contributions involved net income and not taxable income[23]. The negotiations were slowed down probably due to the Spanish economic crisis. In July 1959 a Stabilization Plan to modernize and liberalize the economy was approved. Meanwhile, Spain became a member of international economic organizations, like the IMF (1958), the World Bank (1958) and the OEEC (1959).

In 1959 Spain joined the International Atomic Energy Agency (IAEA)[24], where from 1959 to 1960 Catalá held the post of Chief of the Scientific Exchange Division. Two members of Catalá's group received grants from the IAEA: José Aguilar for 4 months in 1959 at the University of Birmingham and Eugenio Villar for 6 months in 1960 at the University of Milan.

José María Otero Navascués, now president of JEN, visited CERN in early 1960, a year after the inauguration of the PS accelerator. On his return he submitted a report to the government explaining the advantages of Spain entering CERN. On February 16th the government endorsed his report[25]. The following months saw the negotiation of the special and annual contribution from Spain.

Finally, on December 8th 1960, at the 18th meeting of the Council, Spain joined CERN. The decision was adopted unanimously by the 13 member countries. The special entrance fee was fixed at 2,700,000 Swiss francs to be paid in three years. The annual contribution for 1961 was 2,816,300 Swiss francs for a total budget of 67.7 million Swiss francs[26]. Spain became the fifth largest contributor to CERN at 4.16%, ahead of Sweden (4.10%) and Belgium (4.02%)[27].

IFIC and CERN

Prior to the entry of Spain into CERN, Catalá's group had already established many scientific contacts and collaborations. His old friend and collaborator from Bristol, W.Gibson, was in 1959 the head of the CERN emulsion group.

In 1960 Eugenio Villar stayed for 6 months at the Institute of Physics Aldo Pontremoli, in the University of Milan, analyzing an experiment done at the CERN PS accelerator[28].

Catalá was one of the five scientists of the Spanish committee that visited CERN in March 1961. All members were from JEN except Catalá[29].

However, Otero wanted Catalá to play a greater role, strongly supporting him for a position as permanent staff member[30]. Otero argued that Catalá was a good candidate because he was the best known Spanish Nuclear physicist abroad, with a position in the International Atomic Energy and large experience in international work. He added that his candidacy would be supported by W. Heisenberg and E. Amaldi, CERN Council members and C.P. Powell, at the time chairman of CERN Scientific Policy Committee.

He also requested that two disciples of Catalá, F. Senent, then at University of Valladolid, and M. Aguilar, from University of Murcia, could come as visiting scientists.

Finally Otero emphasized that Spain's contribution to CERN represented 10% of the budget of JEN, and that Spain had made a great economic sacrifice at a very difficult time when the country was stabilizing its currency. Spanish membership of CERN implied staff training and opportunity to work within a common European enterprise. He would not have sufficient moral force for defending the continuity of Spain in CERN if positions to Spaniards were few or of little importance.

The case was carefully examined. G. Bernardini reviewed Catalá's scientific output and discussed the matter with Dr. Lock, who had worked with Catalá. He considered the most adequate position to be Research Associate rather than Visiting Scientist[31]. Based on that the Director General answer to Otero was that Catalá could not be admitted as a staff member of CERN, but he could come as Visiting Scientist for one year[32].

In 1963 Spain requested a temporary reduction of the quota to 50% for the next three years. There were four reasons: the income "per capita" was below the European average, there were necessary investments in education and research within the country, there were not physicists with experience in high energy and Spanish industry was not competitive in providing machinery or laboratory equipment. These savings would be allocated to train high-energy physicists in Spain[33].

To strengthen his point, Otero argued at a meeting of the Council that Spain only had the emulsion group led by Catalá, and the contribution to CERN represented 35% of the total budget allocated to physics in the country, much higher than the case of the UK, for instance.

The incorporation of Spain into CERN helped to the consolidation and increase of experimental research in high energy physics at the IFIC[34]. In 1965 there were two groups: photographic emulsions and bubble chamber. The first studied fragmentation processes of heavy nuclei by 13 GeV/c protons and negative pions, and the interaction of antiprotons with nuclei of the emulsion. The bubble chamber group had devoted itself to technical problems due to the lack of appropriate equipment such as the instrument for the evaluation of photographs and electronic calculators[35].

New lines of research were created at IFIC[36]: a group dedicated to environmental radioactivity in atmospheric dust and water, publishing a newsletter since 1958 that had been circulating in most foreign centers performing such

measurements. They had measured the radioactivity produced by nuclear explosions like those from France in the southern hemisphere. Since 1964 there was a theoretical physics group directed by Professor P. Pascual whose purpose was to assist in theoretical aspects of the work of the other groups, doing at the same time original research into the theory of weak interactions.

IFIC and the Spanish Administration

The struggle for institutional recognition was a constant since the group's creation in 1950. Initially IFIC received most of its funding from JEN thanks to the personal relationship between José María Otero Navascués, President since 1958, and Catalá. JEN was a civilian organization created in 1951, first dependent on Government Presidency and later from 1957 onwards on the Ministry of Industry.

JEN signed an agreement in 1955 with the USA for cooperation on the civilian uses of atomic energy in order to launch experimental reactors within the "Atoms for Peace" programme. The early research focused on designs of nuclear research reactors, neutron activities, design and construction of instruments such as counters and management of radioactive fuel[37].

JEN promoted theoretical physics, high energy physics and even molecular biology. It funded the activity of various external scientific groups. Many professors in Theoretical Physics, Mathematical Physics, Quantum Mechanics and Nuclear Physics were first formed at JEN[38].

JEN was the official interlocutor for Spain in CERN, but it did not have any experimental high energy physics group until 1963 when Salomé de Unamuno, after enjoying a fellowship at CERN, along with her husband Bruno Escoubès, mounted a small laboratory to continue the analysis of bubble chamber photographs previously started at CERN[39].

In 1964 the Institute of Nuclear Studies was created for funding and coordinating research related to nuclear energy[40]. In 1966 the National Committee for High Energy Physics was created within the institute on recommendation of CERN, with the aim of coordinating the Spanish research and becoming CERN interlocutor. The honorary president was Otero Navascués, but the effective one was Catalá.

In 1967, IFIC received a special allowance of about 10 million pesetas of the Advisory Commission of Science and Technology for equipment necessary to analyze bubble chamber events. When Spain quit CERN the material was required by JEN to concentrate activities at Madrid. With the equipment two researchers move from IFIC to JEN, Rafael Llosá and Pedro Ladrón de Guevara[41].

IFIC was from its beginnings an associated group to Institute of Optics Daza de Valdés of CSIC. Funding from CSIC was low; in 1957 it came almost exclusively from JEN[42]. It helped to the precarious economic situation of the group that most of its members were Associated or Assistant professors to Catalá's Chair. It was not until 1961 that the Ministry of Education implemented the Physics degree, making Valencia the fourth Spanish university to have it. Through the Ministry IFIC received in 1963 a 5-year grant for research into low and high energy nuclear physics[43].

Concluding remarks

The Valencia group played an important role in the entry of Spain into CERN, thanks mainly to the very close connection of his leader, J. Catalá, with JEN President Otero Navascués. The entry significantly contributed to the consolidation and increase of the experimental research in high energy physics carried out at IFIC, as can be seen from the indicators of scientific output. Funding, which had came mainly from JEN during the 50's, started to increase as well from the Administration in the 60's. This was a straight consequence of the compromise to impulse high energy physics in Spain according to the negotiations from CERN membership.

ISOTOPE LANDSCAPES AND LABSCAPES IN PORTUGAL (1952–1962)

Júlia GASPAR
Centro Interuniversitário de História das Ciências e da Tecnologia, PORTUGAL
julia.gaspar@mail.telepac.pt

Abstract

Political events led to the appointment of Julio Palacios, professor at Madrid University and an experienced researcher in areas other than nuclear physics, as first director of the Centre for Nuclear Physics Studies, and to the choice of its location at a university research hospital, away from the Faculty of Sciences of Lisbon, in 1952. In this site a laboratory was set where isotope applied research was conducted mainly by physicists.
The same year isotope research was also launched at the National Laboratory of Civil Engineering, in Lisbon, by Armando Gibert, ex-teaching assistant at the Faculty of Sciences of Lisbon, and a researcher with experience in nuclear physics. Together with new laboratory premises, isotope work took place by the seaside at the estuaries of the rivers Tagus and Mondego, and at Póvoa de Varzim harbour.
Location in a hospital influenced the lines of research of the Centre for Nuclear Energy which included chemical manipulation inherent to isotope handling, cancer treatment, and physicians training. As for Gibert, he concentrated on a specific topic –tracing sand movements with radioisotopes. Both groups contributed with papers to the International Conference on the Peaceful Uses of Atomic Energy, Geneva 1955, and published in a small number of foreign journals. However, most of the work was addressed to a Portuguese audience through Revista da Faculdade de Ciências de Lisboa*, in the case of the university group, and* Laboratório Nacional de Engenharia Civil *publications, in the other case.*
This talk uses a comparative approach to contrast different backgrounds, profiles and research agendas of two Portuguese research groups both embracing radioisotopes applications in various labscapes and landscapes settings.

In 1952, seven years after two atomic bombs were dropped over Hiroshima and Nagasaki, Portugal was taking its first steps, at the institutional level, to adopt a post-war nuclear energy program. This nuclear turn was truly an audacious adventure, especially driven by the fact that Portugal possessed uranium ore deposits exported to the USA under a joint agreement with the USA and Great Britain, dating from 1949.

This talk addresses investigations concerning, mainly, radioisotopes manipulation by physicists from the Faculty of Sciences of the University of Lisbon. A group of graduate students from this Faculty selected and led by Julio Palacios (1891-1970), physics professor of the University of Madrid, accepted to exchange the academic space for that of a hospital, the Portuguese Cancer Institute (*Instituto Português de Oncologia*). Another group was headed by Armando Carlos Gibert (1914-1985) who had been awarded a nuclear physics PhD by ETH, in 1946. Until 1948, he was physics assistant at the Faculty, and in 1952 he welcomed a research assignment at National Laboratory of Civil Engineering (*Laboratório Nacional de Engenharia Civil*).

We have to go back to 1947 to understand, on the one hand, the peculiar situation of Palacios, a Spanish full professor holding a post at a Portuguese Faculty of Sciences, and conducting nuclear research at a hospital, and on the other hand, Gibert, a nuclear physicist, finding a research post in a civil engineering laboratory. In fact events of a political nature were the excuse for the dictator António de Oliveira Salazar (1889-1970), to dismiss twenty one university assistants and professors of several faculties, of which three were notorious physics assistants and researchers. Two of these physicists were Gibert and Manuel Valadares (1904-1982), the most prominent researcher in radioactivity and nuclear physics in Portugal, at the time. Furthermore Armando Cyrillo Soares (1883-1950), director of the Laboratory of Physics of the University of Lisbon, retired in response to the physicists' dismissals. Palacios was appointed to fill in the void these dismissals introduced into the physics group of the Faculty of Sciences of Lisbon.

On October 10, 1952 a Provisional Commission for Nuclear Energy Studies (*Comissão Provisória de Estudos de Energia Nuclear*) was launched to pave the way for the Nuclear Energy Board (*Junta de Energia Nuclear*) created in 1954. The aim of the Commission was to furnish it with freshly trained specialists, mainly abroad, in all nuclear areas. Back in 1929, although the country was poor and undeveloped both agriculturally and industrially, an institutional system for supervising university research had been installed surviving on meagre budgets ever since its creation. Under the aegis of this institutional system, at the time of this case named High Culture Institute (*Instituto de Alta Cultura*), the afore-mentioned Commission was charged to implement Nuclear Energy Centres of Studies at the Faculties of Sciences of the three universities of Lisbon, Coimbra and Oporto, as well as at the two Engineering Schools of Lisbon and Oporto. However, the Lisbon Nuclear Physics Centre of Studies was an exception to this location rule.

A physics university group working at a hospital space

The choice of a hospital in exchange for the university space has an easy explanation. In 1924 the Portuguese Cancer Institute was created by the government and after the installation of this hospital its director, Francisco Branco Gentil (1878-1964), sought physicists from the Faculty of Sciences of University of Lisbon to aid in cancer treatment with radon. In 1948 this assignment fell both on Gibert and on Palacios, as first assistant and director of the physics department, respectively. Gibert was a radioisotope enthusiast who had tried to rouse Gentil's interest to this new application in medicine as early as 1946. In 1950, Gibert's efforts bore fruit. In April, he and Palacios travelled to England to visit the British Atomic Energy Research Establishment at Harewell and the Royal Cancer Hospital in London. In September 1952, cancer treatment with radioisotopes started at the Cancer Institute in Lisbon, and in April 1953, a Radioisotopes Laboratory was inaugurated there, headed by Gentil with Palacios' collaboration.

However, these events do not explain completely the location of the Lisbon Nuclear Physics Centre of Studies, because there is evidence that the government would not allow nuclear research to be conducted by physicists at the Faculty of Sciences after 1947. In fact, after his dismissal Valadares was granted political exile in Paris, and the appointment as Maître de Recherches at the *Laboratoire de l'Iman Permanent* at Bellevue. Those were cold war times, when communist influence on French nuclear research scientists was intense. In 1950, Frédéric Joliot (1900-1958) had to resign his top post at the *Commissariat à l'Énergie Atomique*, on account of his political positions as president of the World Peace Council, an organization of Soviet tendency. On the other hand there was Salazar, a ferocious anti-communist ruler, and a British and USA ally in the maintenance of a firm anti-communist control in the Iberian Peninsula. He probably believed he would wipe out all sort of French influence on Portuguese nuclear physics research, politically a very sensitive area in those days, by locating the Centre of Studies outside the Faculty of Sciences, where Valadares still had physics disciples.

In November 1952, when the Provisional Commission for Nuclear Energy Studies appointed Palacios as director of the Lisbon Nuclear Physics Centre of Studies, the choices had been made: the space –Cancer Institute– and the topic – radioisotopes research. Palacios had great experience as an experimentalist, but he was not a nuclear physicist. Originally he was a specialist on cold temperatures and lately his interests had moved on to electrochemistry, while collaboration in cancer treatment opened up for him another line of research in radioisotopes. In 1947, when Palacios accepted the post at the Faculty of Sciences he was facing the great challenge of replacing two important men who had succeeded in launching a research school at the Laboratory of Physics of the University of Lisbon: Valadares, the researcher, and Cyrillo Soares, the director of the Laboratory. Palacios soon realized how hard it would be to accomplish his goal of assembling a research group in a Faculty whose vocation was still to train secondary school teachers. Another problem was the backward university system. The Faculties of Sciences did not yet grant a physics degree, but a joint degree in physics and chemistry which meant that specialisation in physics was nonexistent. As an example, let me mention that modern physics –quantum mechanics and nuclear physics– had to wait for the 1964 reform to be included in the physics syllabus. Despite these drawbacks, Palacios succeeded in recruiting collaborators to start research in electrochemistry: in January 1949, António Manuel Baptista (b.1924), a physics assistant, and a year later Fernando Carvalho Barreira (1928-1976) a chemistry assistant. Soon Baptista would join Palacios at the Cancer Hospital to open another line of research linked to radioisotopes: radiation detectors. In 1952 they published their first article on this topic, in *Revista da Faculdade de Ciências de Lisboa*

(*Journal of Faculty of Sciences of Lisbon*).[1] In 1953 Baptista and Palacios were two of the physicists invited by Gentil to collaborate with him at the Radioisotopes Laboratory.

Activities of the Lisbon Nuclear Physics Centre of Studies

In accordance with the Provisional Commission for Nuclear Energy Studies, the purpose of the Lisbon Nuclear Physics Centre of Studies, in line with all other Nuclear Energy Centres, was "to offer young Portuguese graduates theoretical and practical training enabling them to utilize the many possibilities of phenomena relating to nuclear reactions."[2] In 1953 Palacios and his collaborators Baptista and Barreira prepared the installation of the nuclear physics laboratory at the Cancer hospital with modest equipment; an accelerator was something they could only dream of. The same year Baptista and Barreira were awarded scholarships by the High Culture Institute to train in England. From March to July, Baptista worked with Norman Veall in radioactive measures at the Radiotherapeutic Research Unit of the Medical Research Council in Hammersmith. This training ended with a joint article on "multi-tube gamma counting apparatus for small samples."[3] From July to September, Baptista worked with W. V. Mayneord of Royal Cancer Hospital, University of London.[4] In what concerns Barreira, he spent his 1953 summer participating in a theoretical and practical lessons course on radioisotopes at the Isotope School of the Atomic Energy Research Establishment at Harwell.[5]

In 1954 and 1955 the research group was enlarged with more graduates, originating mainly from the physical-chemical course of the Faculty of Sciences, adding up to thirteen participants in the activities of the Lisbon Nuclear Physics Centre of Studies. A sub-division occurred then, one around Baptista dedicated to radiation detectors and radioactive measures, and another around Barreira with more diversified interests. Studies of iodine-131 and atmospheric radioactivity were predominant, but others such as range determination of beta particles and irradiation with neutrons are also to be found.[6] The Portuguese journal *Revista da Faculdade de Ciências de Lisboa*, a journal dedicated to publishing research work of faculty members, was an easily reachable vehicle for publications written mostly in Portuguese, and sometimes in French and English. This circumstance accounts for *Revista* circulating outside Portugal. Actually, the contents of one of these articles[7] was the object of a controversy between the authors and D. Blanc of the *Laboratoire de Physique Atomique et Moléculaire du Collège de France*. The Portuguese reply found its way to the Italian journal *Il Nuovo Cimento*.[8]

Apart from involvement in research, Palacios and his group also organized training sessions in nuclear physics. Their first activity outside the laboratory aimed at furnishing graduates from the Higher Technical Institute (*Instituto Superior Técnico*) with preliminary notions on nuclear physics before their departure for foreign laboratories. In 1954 and in 1956 the courses lasted two months and the recipients were technicians from the Nuclear Energy Board. In 1956 and 1957, the courses were dedicated to physicians, the first lasting six months and the second a little over two months. Physicians also collaborated with physicists in delivering some of the lessons of these courses.

In 1958 the First Meeting of Portuguese Nuclear Energy Technicians (*1ª Reunião dos Técnicos de Energia Nuclear*) was an important event also for Palacios and his group, as revealed by the report he submitted. Palacios' assessment of the activities of the Centre of Studies he directed was clearly positive. Although the means at his disposal were parsimonious, "in accordance with its goals the young physicists were trained adequately in handling radioactive bodies, as well as in the study of the phenomena taking place inside them."[9] He also stressed the fact that articles were published in foreign journals. At the time Palacios' vision of future development of the Centre was undisturbed by the prospect of a Laboratory of Nuclear Physics

and Engineering (*Laboratório de Física e Engenharia Nucleares*) on the way to be constructed in Lisbon, under the Nuclear Energy Board, to house a research nuclear reactor and two accelerators. His arguments were that physicists still needed to be trained in close partnership with the Faculties of Sciences, collaboration with the Cancer Hospital had been productive and should be maintained, and the Lisbon Nuclear Physics Centre of Studies possessed equipment and human resources able to construct radiation detectors which could evolve to industrial scale production.[10]

The real situation, however, was different. By the end of the 1950s it was possible to predict that the Lisbon Nuclear Physics Centre of Studies was to close in the short term. For several reasons Palacios' group began splitting up, slowly, and its leader was the first to set this trend. In October 1953 he returned to his post in the University of Madrid with the understanding that he would work fifteen days per month in Portugal.[11] This situation ended in November 1958 when he stopped collaborating with the Faculty of Sciences[12], retiring in 1961. However, the greatest threat to the group's integrity was the installation of the Laboratory of Nuclear Physics and Engineering, inaugurated in 1961, because members of Palacios' group were natural candidates to posts in this Laboratory and some of them were indeed recruited.

The research work published by the Centre involved investigations, most of them on selected topics: radiation detectors, study of iodine-131 and atmospheric radioactivity, clearly in syntony with a research laboratory aiming at developing physics methods and instrumentation addressed to cancer treatment. Taking into account the scientific unpreparedness of the graduates, we must recognize that Palacios' group made a remarkable effort. These results can be explained not only by Palacios' experience as an experimentalist but also by his commitment to the new task.

Nuclear Physics Applied to Civil Engineering

In 1952, Gibert was invited by Eduardo Arantes e Oliveira (1907-1982), director of the National Laboratory of Civil Engineering, to study the problem of sand drift by sea water. At the time radioactive tracing was a new method first studied by English researchers, based on the production of glass powder with a radioactive isotope, scandium 46, to be mixed with the sand grains. This practice was implemented in 1954. France and Japan followed the English procedure, while Gibert's group located at the civil engineering Laboratory used a different method.[13]

Theoretical research conducted by Gibert showed that radioactive tracers could be deposited on sand grains by an electrochemical process, with the limiting conditions that they should have a minimum half-life of 90 days, and a maximum not exceeding a few months, and that radiation emission should be easy to detect.[14] The choice fell on the radioactive isotope silver 110, with 270 days half-life, and strong gamma-ray emission of about 1.3 MeV. Experimental studies followed closely the theoretical ones in order to develop an adequate method[15]. In 1955, when Gilbert delivered his talk at the First International Conference on the Peaceful Uses of Atomic Energy, he announced the construction of a radioisotope laboratory at the National Laboratory of Civil Engineering. At the time a live trial had not yet been performed.[16]

The first live trial took place later at the river Tejo's mouth, in Cova do Vapor, under unfavourable conditions, aiming at establishing the comparison with the glass powder method. The results of this trial led to the conclusion that, on several parameters, the Portuguese method was more advantageous than the method based on glass powder. It was then decided to hold the next trial north of the port of Figueira da Foz, a city in the centre of Portugal near the mouth of river Mondego[17]. On July 1, 1957, 4,000 kg of sand labelled with 800 mc of silver 110 were dumped at a point of the beach about 2 km north of Cape Mondego. The samples collected in July, August and September enabled researchers to establish the sand drift in

the foreshore in the area of Mondego Cape and of Buarcos Bay, and in this Bay not only in the foreshore but also down to a depth of 6,0 meters at least.[18]

In the 1960s, the technicians of the National Laboratory of Civil Engineering followed a new method based on bone glue developed by Soviet scientists. This new method allowed for a wider choice of radioactive labels than the previous one because it was possible to coat the sand grains with a waterproof membrane of glue which protected the radioactive element. The radioactive isotope selected was Phosphorus-32, with a half-life of 14.2 days, emitting high energy beta radiation, requiring less precaution than gamma-emitting isotopes. This time the purpose was a detailed study of the coastal drift in the Póvoa de Varzim harbour, in the north of Portugal. The method was considered extremely interesting concerning its sensitivity and the quickness in obtaining results.[19]

Concluding Remarks

There is no exact information as to when activities ceased at the Nuclear Physics Centre, nevertheless it can be deduced, by publications and the training abroad of its most important members, that it hardly survived after 1958. This was the year Palacios' link with the University of Lisbon was broken. By this time the Centre had fulfilled the aim of the Provisional Commission for Nuclear Energy Studies: "to offer young Portuguese graduates theoretical and practical training enabling them to utilize the many possibilities of phenomena relating to nuclear reactions".

The research work published by the Centre involved investigations on selected topics which were influenced by Palacios' and Baptista's direct collaboration with the Radioisotopes Laboratory of the Cancer Institute. The Centre's contribution to the training of specialists in nuclear areas helped to pave the way for the Nuclear Energy Board, which came into existence in 1954. At the end of the decade, ex-members of the Centre would actively participate in installing Nuclear Physics and Engineering Laboratory and Calouste Gulbenkian Laboratory of Mass Spectrometry and Molecular Physics. On the other hand, Baptista's appointment at Radioisotopes Laboratory of Cancer Institute, after 1953, meant a great contribution of the physicists to cancer treatment with radioisotopes.

Gibert's experience at the National Laboratory of Civil Engineering was ended by December 1960, also a short lived experience. Today there is no trace of it in the official history of this Laboratory. It seems that Gibert was not successful in implementing a durable radioisotopes practice in sand drift.

THE AMERICAN INFLUENCE ON THE ORIGINS OF NUCLEAR PHYSICS IN MEXICO

María de la Paz RAMOS LARA
Centro de Investigaciones Interdisciplinarias en Ciencias y Humanidades,
Universidad Nacional Autónoma de México, MÉXICO
ramoslm@servidor.unam.mx

Abstract

In 1938 arrived to Mexico the expert in nuclear physics Marietta Blau (Austrian physicist), who worked at the National Polytechnic Institute –Instituto Politécnico Nacional*. However, she decided to move to the United States in 1944 without producing any incidence in the development of this field. Years later, several Mexican students returned to Mexico after finishing their doctoral studies in US universities. Two of them promoted nuclear physics at the University of Mexico. Marcos Moshinsky worked in theoretical nuclear physics while Nabor Carrillo promoted experimental nuclear physics acquiring equipment from US companies. In addition, Manuel Sandoval Vallarta, the first Mexican with a Ph.D. from the Massachusetts Institute of Technology, Carrillo and the Mexican physicist Carlos Graef were the first scientists who represented Mexico in the international meetings of nuclear energy.*

From French to American influence. Mexican students graduated in physical sciences in the United States

Several countries have inevitably influenced the development of physical sciences in Mexico. After prevailing during the nineteenth century, the influence of France gradually declined in the first decades of the twentieth century, when due to World Wars I and II the United States began to influence Mexican science. Specifically, the First World War forced young Mexican students interested in science to pursue postgraduate studies in the United States.

Such was the case of the first Mexican Ph.D. in Physics, Manuel Sandoval Vallarta (1899-1977), who graduated from the Massachusetts Institute of Technology (MIT) in 1924. He worked for the MIT for almost twenty years. At the beginning, in Mexico there were no physics degree programs, let alone research institutions. Before long, he became one of the most prominent and renowned scientists in the world, one who had decidedly contributed to the transformation of MIT, which became a major scientific institution in the United States.

The international renown of his work earned in the United States in the 1930s positioned Sandoval Vallarta on the research axis around which physics revolved in Mexico for some years. His talent encouraged university authorities to develop the first physics curriculum and to set up the first physics research center at the National Autonomous University of Mexico –*Universidad Nacional Autónoma de México*, UNAM.

Some Mexican students decided to join him at MIT to carry out their postgraduate studies in physics. When they returned to Mexico, they took charge of the Institute of Physics and other scientific institutions. Among these students were Alfredo Baños Jr. (1905-1994) and Carlos Graef Fernández (1911-1988), who graduated in MIT. Baños returned to Mexico in 1938 to become the director of the first Institute of Physics in Mexico, whereas Graef endeavored to promote the development of experimental nuclear physics (also the relativity field) and the projects of his friend and fellow student, Mexican engineer Nabor Carrillo (1911-1867).

Thanks to Sandoval Vallarta, institutional relations with the United States improved significantly. American experimental equipment began to be imported, collaborative research agreements were signed, US fellowships were promoted among Mexican students, and American scientists were invited to give lectures mainly at the UNAM. Furthermore, collaboration with American physics associations became closer and international congresses were held in Mexico.

When the United States decided to enter World War II, Sandoval Vallarta returned to Mexico. Because of his international prestige, he played a central role at national and international forums that discussed the uses of nuclear energy. In Mexico, he was a member of the National Commission on Nuclear Energy –*Comisión Nacional de Energía Nuclear*, CNEN–, created in 1955, and a scientific advisor and representative of the Mexican government in international events. In Mexico, he was appointed to several important academic and government posts, including Minister of Public Education, Director of the National Polytechnic Institute, and President of the Commission for the Promotion and Coordination of Scientific Research –*Comisión Impulsora y Coordinadora de la Investigación Científica*, CICIC.

World War II strengthened American influence on the development of nuclear physics in Mexico. Some US mathematicians, who disagreed with their country's war policy and wanted to live in Mexico, established contact with local scientific institutions. One of those scientists persuaded and helped Marcos Moshinsky Borodiansky (1921-2009) –Sandoval Vallarta's undergraduate student, and pioneer and promoter of theoretical nuclear physics in Mexico– to apply for a fellowship at Princeton University, where he met some of the best physicists of the world, who because of the war had fled Europe and were working at that institution.

After staying in different European cities that had been devastated by the war, Moshinsky adopted the strategies those countries were implementing to revive science. Some of those strategies included summer schools –which allowed the new generations to meet bright scientists–, development of a physics curriculum for young students, application for fellowships for international postgraduate programs, organization of national and international congresses, and production of rigorously peer reviewed journals.

In a matter of years, Moshinsky became one of the main promoters of physics, particularly theoretical nuclear physics. Among other activities relevant to the development of this field of knowledge in Mexico, he gave undergraduate and postgraduate courses, supervised theses and dissertations, secured fellowships for students who wanted to study in Europe and the United States, invited renowned foreign physicists to participate in international congresses and the like, chaired the Mexican Society of Physics –*Sociedad Mexicana de Física*–, and was the editor of the Mexican Physics Journal –*Revista Mexicana de Física*.

Moshinsky rapidly gained international renown, and put Mexico and the Institute of Physics on the world map of physics thanks to his contributions in group theory, which had remarkable applications in atomic, molecular, and nuclear physics.

European nuclear physicits activity in Mexico

Due to the Second World War and the Spanish Civil War, hundreds of European scientists came to Mexico, but unlike biomedical, biological, and chemical sciences, physics did not benefit much from this influx, despite the arrival of a few European physicists, such as Marietta Blau (1894-1970), renowned Spanish physicist Blas Cabrera (1878-1945), Spanish astronomer Pedro Carrasco Garrorena (1883-1966), and German physicist Thomas Brody (1922-1988). Blau and Brody worked in nuclear physics, while Cabrera focused on disseminating nuclear physics information through science magazines.

To understand the context in which nuclear physics projects were launched, it is important to further examine the Mexican situation in 1938. In the 1930s, the UNAM developed the first physics curriculum. In 1938 the Institute of Physics was founded and Alfredo Baños Jr. (who had recently finished his doctorate studies at MIT under Sandoval Vallarta's supervision) was appointed its director. The Institute staff consisted of four researchers and a research assistant; only the director had a doctorate degree.

At the beginning, the main research lines were cosmic radiation, hydrodynamics and elasticity, biological physics, nuclear physics and radioactivity, spectroscopy and atomic structure, X-rays and molecular structure, astrophysics, geophysics, and soil mechanics laboratory. The cosmic rays project was the institute's most important undertaking; it operated under the supervision of Sandoval Vallarta at MIT, and in Mexico when he was there on vacation.

On the other hand, Mexico was going through important social, political, economic, and scientific changes. President Lázaro Cárdenas (1895-1970) had introduced substantial social, political, and economic reforms, aiming at decreasing

Mexico's dependency on other countries. To that end, he expropriated the assets of some foreign companies to create national entities, among them the state oil company PEMEX. In education, Cárdenas promoted higher technical studies to train technicians and specialists in industry-specific issues necessary to boost the country's economy.

It was in this context that the National Polytechnic Institute (IPN) was created in 1936. The IPN comprised several technical schools that had been founded years before. Among these was the Higher School of Mechanical and Electrical Engineering –*Escuela Superior de Ingeniería Mecánica y Eléctrica*, ESIME–, where Marietta Blau started working in 1939.

Between 1937 and 1942, that policy allowed hundreds of specialists in various scientific fields to become faculty and researchers in different Mexican education institutions, among which the UNAM and the IPN were the most important. Since the UNAM had become autonomous in 1929, a capacity that prevented government institutions from influencing its decisions, Cárdenas founded the IPN within the Ministry of Public Education –*Secretaría de Educación Pública*, SEP.

Of that influx of scientists, only a few were physicists. Hence, they exerted little influence on the development of physics, as compared to fields such as the biomedical, biological, and chemical sciences, to which Spanish exiles contributed greatly. Marietta Blau, for example, came to Mexico but left for the United States some years later. Blas Cabrera, an eminent Spanish scientist, died in Mexico after a few years due to a preexisting condition. Thomas Brody, in contrast, stayed and worked with Marcos Moshinsky in theoretical nuclear physics.

One of the problems facing Blau at the IPN was that the department for which she worked did not have a research budget, as it was only part of an engineering school. Therefore, since she could not live exclusively on her income as an ESIME professor, she had to teach in other institutions. This was a widespread problem among education institutions, and the professors had to teach at several schools to earn a decent income. This allowed her to meet several scientists who taught at both the IPN and the UNAM. Strangely enough, she never gave classes at the UNAM or collaborated with the Institute of Physics, which carried out research in several fields, including nuclear physics.

Marietta Blau was working with Sandoval Vallarta as Head of the Radioactivity Laboratory of the Commission for the Promotion and Coordination of Scientific Research (CICIC). She worked with Sandoval Vallarta at the same time that Nabor Carrillo, but Carrillo was responsible for the project *Estudio del subsuelo de la Cuenca de México* (A Study of the Subsurface of the Mexico Basin). When she decided to go to the United States (in 1944), she didn't know that Carrillo would be the most important promoter of experimental nuclear physics in Mexico.

Nabor Carrillo, main promoter of experimental nuclear physics in Mexico

The main promoter of experimental nuclear physics in Mexico was the Mexican engineer Nabor Carrillo. Because of the Spanish Civil War, he was not able to study with Blas Cabrera –as he had originally intended– but completed postgraduate studies in soil mechanics at the University of Harvard. Carrillo had the opportunity to be present at one of the atomic bomb tests on the Bikini Atoll site in 1946, which convinced him that Mexico had to join the nuclear age.

Coincidentally, Carrillo attended the university where Van de Graaff, the creator of the eponymous particle accelerator, worked. His Ph.D. supervisor was the brother-in-law of one of the owners of the High Voltage Engineering Corporation, a manufacturer and seller of particle accelerators. During a visit to the company's facilities, Carrillo, mesmerized by the potential applications of this equipment in various fields, especially medicine, decided to buy an accelerator for the UNAM –the most costly device in the history of the university.

When Carrillo was appointed President of the UNAM, he already enjoyed international recognition. He was regarded as one of the leading experts in soil mechanics because with a simple method he had been capable of solving the serious problem of subsidence in the Long Beach area. He took advantage of his position at the university to support scientific projects, especially those related to nuclear physics. Also in that capacity, he signed agreements with health institutions to promote the use of nuclear physics in medicine, as the 2-MeV Van de Graaff accelerator –installed in 1952 and the first of its kind in Latin America– and the necessary infrastructure were already in place.

Regarding the use of nuclear energy, Carrillo had other more ambitious projects, which he developed after his tenure as president. With the CNEN, of which he was a Board Member –as was Sandoval Vallarta–, he started negotiations to purchase Mexico's first nuclear reactor. As the cost of the reactor was way over the budget of the UNAM, the largest and best funded university in the country, he decided to seek support from the government, which showed no interest in the project.

This situation improved with the American exhibition "Atoms for Peace," held on the grounds of the Campo Marte military base in Mexico City. Finally, in 1963, a Triga Mark III Reactor was purchased from the American company *General Atomic*. The reactor was installed at the then Nuclear Center of Mexico, known today as the Nabor Carrillo National Institute for Nuclear Research. Unfortunately, Carrillo died prematurely, leaving other projects unfinished.

Acknowledgments

My gratitude to the DGAPA-UNAM for finantial support throught the proyect IN300070.

NUCLEAR AND SUBNUCLEAR PHYSICS IN ITALY IN THE SECOND HALF OF THE 20TH CENTURY

Luca MALAGOLI
Department of Physics and Relative Technology (DIFTER), Università degli Studi di Palermo, ITALY
malagoli@difter.unipa.it

Abstract

Before World War II, two departments were principally active in Italy, known in all the world: Arcetri (near Florence) and Rome. The promulgation of racial laws (1938) and the worsening of work condition caused the departure of most of the best know Italian physicists.
During WW II the remaining part of ex Fermi's group took a very important decision for their future: to avoid any involvement in the war, they left off the nuclear physics studies. They preferred to move towards different fields of research, in which the costs were at stake for a hard knocking Nation from the war.
The years immediatly after WW II were characterized, in Italy, by a very difficult reorganization, also in the fields of physics. The work of reconstruction of Italian physics was undertaken by members of the two principal groups of research presented before the war. In particular, it's right to give attention to Amaldi (Fermi's group) and Bernardini (Arcetri's school); with which a large number of important physicists worked to get ahead to the rebuilding operations.
The availability of some departments with a good level of research was fundamental to continue in the rebuilding works, together with the help of a research institute, the INFN, placed over all the country.
In particular physics, the Italian contribution took place in Frascati's Laboratory building, where there were established an electrosynctrotron –a prototype for more collider generations– and the AdA's accelerator with its follower Adone; in the participation to CERN's building; and in the building of a laboratory in Legnaro, Catania and Gran Sasso.
The winning of the Nobel Prize by Rubbia (1984) for the discovery of the boson vector $W^{\pm}$ e Z^{0} represented the peak of the Italian contribution to particle physics. On theoretical aspects, the main results were Puppi's triangle, the introduction of Cabibbo's angle, and the fourth quarks by Maiani (with Glashow and Iliopoulos).

At the beginning of the 20th century, while European physics was discovering new paths towards new theories, in Italy the situation was very different because there wasn't any attention to the new physics. In Italy there were some good centres in which experimental physics was at a good level, but there were no physicists that gave any attention the new theories such as relativity, both special and general, and quantum mechanics.

This situation changed in 1926, when Enrico Fermi obtained in Rome the first teaching of theoretical physics: it was the start of a new era for Italian physics, an era in which Italy became a cornerstone in the new fields of research, in particular in nuclear physics and cosmic rays physics. At the same time in this period the foundations were put for what would be the (re)building of Italian physics after World War II (WW II).

Together with the work of Fermi in Rome, there was similar work made by Bruno Rossi in Arcetri (near Florence): it's possible to assert that there were two schools for Italian physics in the first half of the 20th century: Rome and Arcetri. And it would be these two schools which would play a fundamental role in the (re)birth of Italian physics after WW II. Obviously, there were in Italy a lot of other situations in which it was possible to study good physics, but these other places were all devoted to experimental physics with particular attention to classical physics.

School of Arcetri – main members	School of Rome – main members
Enrico Persico Gilberto Bernardini Giuseppe (Beppo) Occhialini Daria Bocciarelli Bruno Rossi Guglielmo Righini Beatrice Crinò Giulio Racah Lorenzo Emo Capodilista	Edoardo Amaldi Franco Rasetti Enrico Fermi Bruno Pontecorvo Gian Carlo Wick Ettore Majorana Oscar D'Agostino

A problem of historical studies is its potentially subjective character; it would be a good result to find an objective system to evaluate facts. In this perspective, in my work attention is given to some parameters by which we can evaluate the quality of a physics school: such parameters are, first of all, coincident with the number of articles and prizes obtained by the school. So in this work I have taken into account all the articles written by Italian physicists in the period 1900-1940 and published in *Il Nuovo Cimento*, the principal Italian physics review, in particular in the period before WW II. At the same time the subjective evaluation takes into account the prizes awarded to Italian physicists in the same period, with particular attention to the Nobel Prize and to international prizes available after WW II, such as Dirac medal, Wolf prize, Dannie Heineman prize, Tate medal, etc. Last but not least, the international role played by a school of physics could be measured by the importance of the Congress organized in the country. From this point of view, Italy obtained the right acknowledgment with the Rome Congress in 1931, the first Congress on nuclear physics in which all the best nuclear physicists was present.

It is possible to summarize this work using two graphics in which I give a scheme of the work. As it is the case for all such schemes, also in this case schematization introduces a work simplification, but it is useful to understand the guideline of this work.

* * *

Before starting it is very important to underline that in Italy, in the same years, there were a lot of different realities, much of them very important from the point of view of the work that was made inside: with Rome and Arcetri, also Turin, Milan, Bologna, Naples, Palermo and other Institutes were the place in which experimental work was made in physics. But it's also true to assert that some Institutes were more important than others. In particular, without the work made in Rome and in Arcetri, Italy wouldn't have regained a guide role in physics in the Thirties, and it would be impossible to start the rebuilding work after WW II.

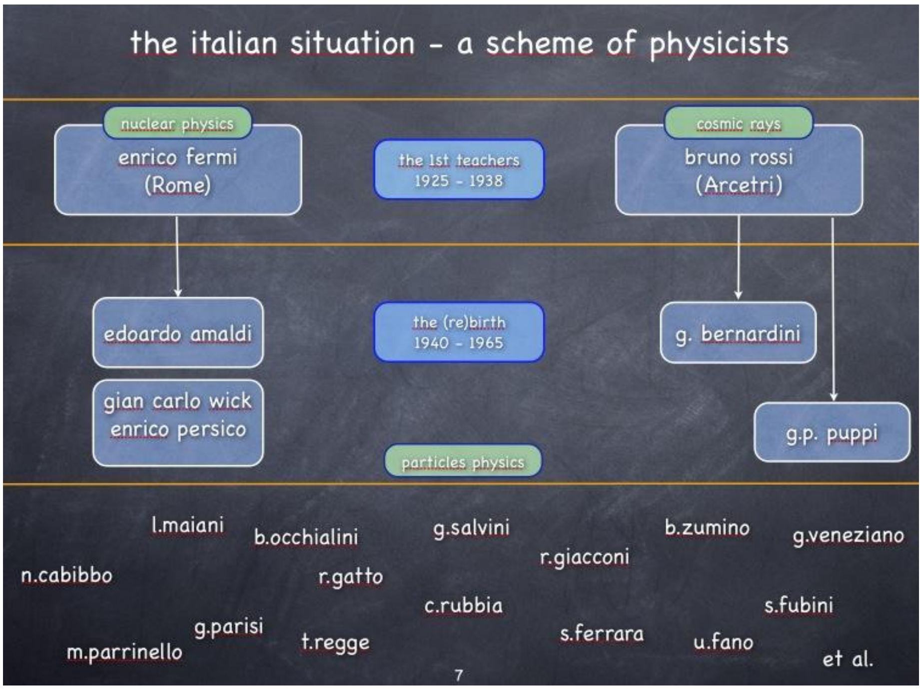
My idea is that there was a first level of teachers of Italian physics, and these teachers were Bruno Rossi and Enrico Fermi. Obviously, these two teachers were working in a complex context, in which other very important physicists were present, such as Orso Mario Corbino, Antonio Garbasso and Enrico Persico. The first two played a fundamental role from the political point of view; in fact, Corbino, who was a physicist, covered a lot of very important roles in the Italian government, and gave a big impulse to the composition of the school of physics in Rome. At the same time, Garbasso played an analogue role in Florence; in fact he was the mayor of the city and from this political charge he helped the daily life of the Arcetri Institute, where Rossi and Persico worked.

For the physicists in Arcetri, Enrico Persico was an important teacher that helped young physicists to improve their knowledge, in particular in the field of quantum mechanics. All the members of the Arcetri's group remembered Persico for the attention he posed in the preparation of his lessons; in fact, two of them recollected Persico's lessons in a book.

It is known that towards the end of the Thirties in Italy the majority of the physicists were forced to leave the country due to the odious racial laws that were promulgated by the Italian fascist regime. So, near the start of WW the Italian physics was in a very difficult situation, with only a few physicists that could decide to stay in their own country. Among them we could remember Edoardo Amaldi and Gilberto Bernardini, each one a member of each of the previously mentioned schools. They will be the cornerstone on which Italian physics will be (re)built after WWII. It's obvious that there were a lot of other physicists in Italy in the same period, and some of them played a very important role, but the polar star of the new start of physics in Italy was due to only some of them. Together with Amaldi and Bernardini, it is right to remember also Gian Carlo Wick and Enrico Persico. The first of these two left Italy near the end of the Fifties, and the second one covered the reverse path in the same period, after a very particular human adventure[1].

In the same scheme also Giampietro Puppi is shown: it's a different, more particular case but also very important for the renaissance of physics in the city of Bologna, the oldest Italian university. Puppi's work was mostly localized in the Department of Bologna, where he arrived after WW II. In that Institute the situation was very difficult, because before Puppi in Bologna worked Augusto Righi and Quirino Majorana, two physicists as good in experimental work as far from new physics[2]. Puppi's work was devoted, first of all, to the reformulation of the research fields on the path of new physics and to the search of new money to guarantee the possibility of organizing a good and long term research work.

All the other names indicated in the bottom of the picture are some of the physicists that continued the work started after WW II.



* * *

In the previous pages it was indicated that the fields of research in Italy before WW II were, in particular, nuclear physics and cosmic rays physics. These two fields represented the base for the development of new fields on physics research in Italy after WW II: elementary particle physics.

The path towards elementary particle physics was characterized by some key points. Among them it's possible to indicate:

- the invention of the coincidence circuit, due to the work of Bruno Rossi in Arcetri towards the end of the Twenties (a work in the field of cosmic rays);
- the discovery of the slow neutron, due to the work of Fermi and others in the middle of the Thirties (a work in the field of nuclear physics);

---

[1] In the picture of the (re)building of Italian physics, Amaldi knew that a physicist like Persico was fundamental; so he proposed him to return to Italy from Canada, but due to a dramatic medical reference Persico had to refuse the proposal. After a lot of time and after a new medical check, Persico knew that the first medical information was wrong and his health was good, so he could finally return to his own country.

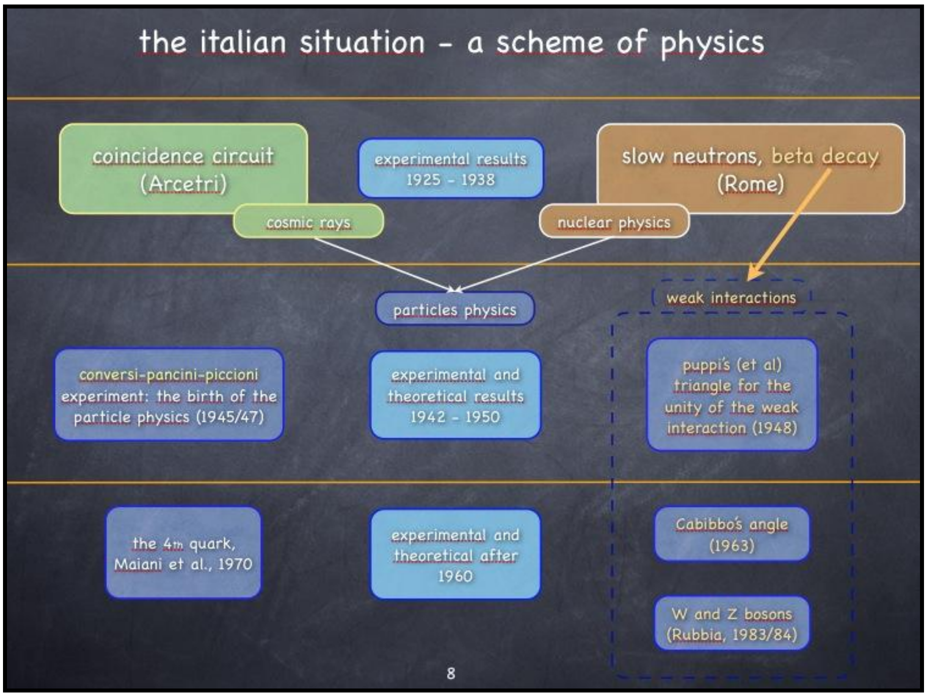
[2] It's to note that the words "new physics" indicate the physics born at the beginning of the 20th century (relativity and quantum mechanics), a physics which was around 30 years old, and on which also a lot of Nobel Awards had focused.

- the experimental work of Conversi-Pancini-Piccioni in 1943 in Rome[3], under the bombing of the Allied force: this is considered the work that starts the era of elementary particle physics.

These last three points represent the base on which the restart of physics will be built; in particular the first results obtained were in the field of weak interaction. Also this is a path that started in the past: one of the first fundamental articles of Enrico Fermi spoke about the β-decay. After this start, in the following years a lot of new articles opened the street towards a very important role played by Italian physicists; in particular the work of Puppi in 1948[4] meant an important goal. After that it is right to remember Cabibbo's work in 1963, a work defined by the Royal Swedish Academy of Sciences as a *"cornerstone of the weak interaction"*[5]

The line started with the cited article by Fermi, and found its end in 1983 with the Nobel Prize awarded to Carlo Rubbia[6] for the experimental discovery of the W and Z vector bosons.

Another very important goal obtained on this path started with the work of the Rome and Arcetri groups, and was the theoretical introduction of the fourth quark, proposed in 1970 by Luciano Maiani and others[7].



* * *

As indicated in the previous lines, one of the feature of this work is to find an objective system to evaluate the quality of the work in physics in a country, or in a part of a country. One system is counting the number of articles divided by topics published on specialized magazines. In the Italian case the first step is to count the number of articles published on *Il Nuovo Cimento* in the period from 1900 to 1940. To deepen the analysis it is possible to divide the period in two steps: the first one from 1900 to 1920 and the second one from 1921 to 1940. This division is not casual, but corresponds to the change that was starting in Italy: the advent of the new physics also in Italy by the work of the forthcoming school of physics.

---

[3] Due to the very particular work conditions during the war years, this work was published only in 1947.

[4] At the same time also Tiomno and Wheeler obtained the same result; each of one of them independently.

[5] Class for Physics of the Royal Swedish Academy of Sciences, *Broken Symmetries*, (2008).

[6] The Nobel Prize was awarded jointly to Simon van de Meer.

[7] S.L. Glashow, J. Iliopoulos, L. Maiani (1970). "Weak Interactions with Lepton–Hadron Symmetry". Physical Review D **2** (7): 1285–1292.

JOURNAL	TOPIC	N art.	%
Il Nuovo Cimento 1900-1940	Zeeman effect	9	2%
	Cathod rays	10	2%
	Cosmic rays	14	2%
	Relativity	25	4%
	X rays	35	6%
	Radioactivity	42	7%
	Nuclear Physics	53	9%
	Quantum physics	90	15%
	Electricity	134	22%
	Electromagnetism	184	31%
		414	**69%**
		182	**31%**

JOURNAL	TOPIC	N art.	%
Il Nuovo Cimento 1900-1920	Cosmic rays	0	0%
	Nuclear Physics	0	0%
	Quantum physics	2	1%
	Zeeman effect	6	2%
	Cathod rays	10	3%
	Relativity	11	4%
	X rays	21	7%
	Radioactivity	32	11%
	Electricity	79	28%
	Electromagnetism	125	44%
		286	**100%**

JOURNAL	TOPIC	N art.	%	Δ
Il Nuovo Cimento 1921-1940	Cathod rays	0	0%	**-3%**
	Zeeman effect	3	1%	**-1%**
	Radioactivity	10	3%	**-8%**
	Cosmic rays	14	5%	**5%**
	Relativity	14	5%	**1%**
	X rays	14	5%	**-2%**
	Nuclear Physics	53	17%	**17%**
	Electricity	55	18%	**-10%**
	Electromagnetism	59	19%	**-25%**
	Quantum physics	88	28%	**27%**
		310	**100%**	

It's possible to find some clear indication: a lot of topics, such as Cathod rays, Zeeman effect, X rays, Relativity, show small variation (in rate), while some other topics show big variation in rate, as positive as negative. In particular is interesting to note the small variation of the rate in Relativity (+1%); also the variation of Cosmic rays is small in rate, but it's important to underline that this topic is starting from a null rate.

Other topics show a big change in rate; in particular it is possible to note a big reduction in the rate of Electricity and Electromagnetism, and, at the same time it's noticeable the positive change of Nuclear Physics and Quantum Physics: all this indications tell us that the topics change was started also in Italy, and the effect of this change started to be evident.

* * *

The analysis of publications of Italian physicists before WW II would be deep with graphs and other possible readings of the data. But in a brief article like this it's time to go to the analysis of similar data referred to the period after WW II. Before the war, in Italy the majority of articles were published on a single magazine, but after the war this practice changed. So the first path to walk is to find the right source from which to extract the correct data. For this period I detected four different sources, that I list now:

- The Physical review – the first hundred years
- http://www.springerlink.com/
- http://scitation.aip.org/
- http://publish.aps.org/

The first one is a publication in which all the articles that are considered the most important articles are collected, divided in topics:

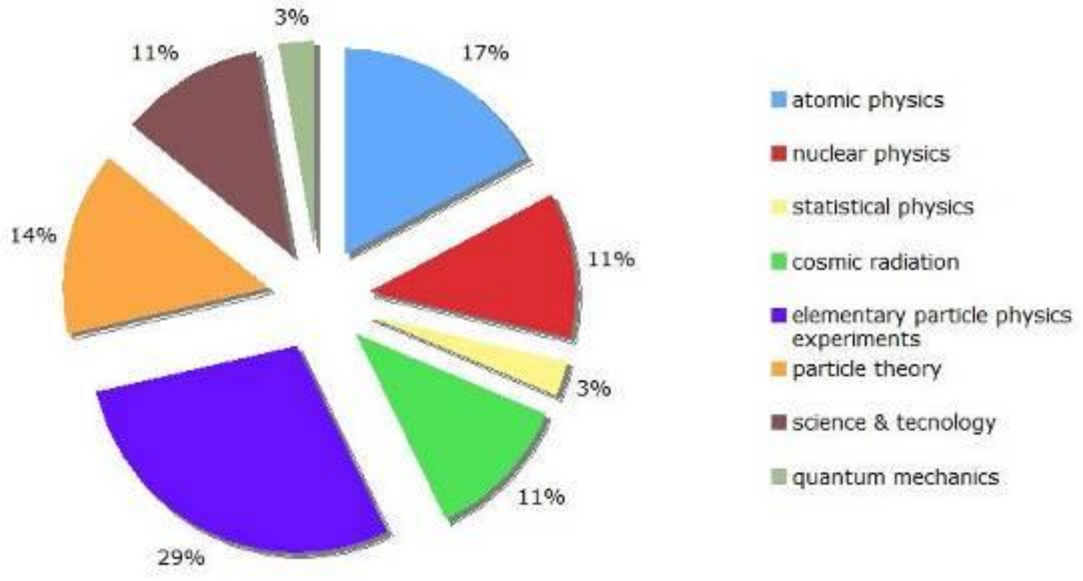
> "*The Physical Review-The First Hundred Years* is a selection of seminal papers and commentaries highlighting the developments in physics and their applications presented in printing and electronic form.
>
> The publication of this collection is sponsored jointly by the American Physical Society and the American Institute of Physics in the celebration of the 100th anniversary of *The Physical Review*".[8]

The other three are internet sites in which a lot of scientific magazines are recollected, such as: *Il Nuovo Ciment, Zeitschrift für Physik* (springerlink.com); *Physical Review Letters*, *Review of Modern Physics*, *Physical Review A – E* (publish.aps.org); *Physics Today*, *Physics Review*, *AIP Conferences Proceedings*, *Review of Scientific Instruments* (scitation.aip.org).

In the case of *The Physical Review* it is possible to extract the data referred to the Italian physicists. Once these data in a table, and then in a graphic, it is possible to discover some interesting information:

Subject	N art.	%
atomic physics	6	17%
nuclear physics	4	11%
statistical physics	1	3%
cosmic radiation	4	11%
elementary particle physics experiments	10	29%
particle theory	5	14%
science & tecnology	4	11%
quantum mechanics	1	3%
TOTAL	**35**	**100%**

[8] *The Physical Review. The first hundred years*, pag V.



Percentage of Italian articles by subject.

It's possible to note that there is a clear prevalence of the topic called "Elementary particle physics experiments", following from the topics called "Atomic physics" and "Particle theory". From my point of view it's a clear result caused by the choice to deepen nuclear physics and cosmic rays before WW II. At the same time there are some other topics with a good rate of articles in the first hundred years of the magazine. In each case it is needed to underline that the period covered by this book starts in the end of the 19th century (at around 1894) and ends in 1994; in other words, within the total number of articles, a lot of them were written before WW II, hence in the period corresponding to the predominance of classical physics in Italy.

* * *

As indicated in the first part of this article, I focused my attention on some of the main physicists involved in the (re)building work of Italian physics. I explained mi choice in the starting part of this work, and now I try to finish this path. To go towards the end of this path I need to analyze the data available from the previously listed sites; in this article I give only an indication of a more complex work that has found its completion in my Ph.D. thesis.

As a starting point it is possible to use the total number of articles written by this four physicists in the period 1932-1996[9]:

Number of articles from 1932 to 1996			
Edoardo Amaldi	Gilberto Bernardini	Gian Carlo Wick	Giampietro Puppi
75	46	37	39

Starting from this data is possible to organize some particular reading; for example, is possible to identify the moment that corresponded to the passage from the nuclear to the particle physics. From the case of Edoardo Amaldi:

[9] The fabulous four are: Edoardo Amaldi, Gilberto Bernardini, Gian Carlo Wick and Giampietro Puppi. The chosen period starts with the publication of the first articles and ends with the last particles paper written by one of the fabulous four.

NUCLEAR PHYSICS	1932	1933	1934	1935	1936	1937	1938	1939	1941	1942	1943	1946	1947	TOT.	%
Naturwissenschaften	1									1	1			**3**	**13,0%**
Zeitschrift für Physik	1	1												**2**	**8,7%**
Proc. R. Soc. Lond.			1	1										**2**	**8,7%**
Il Nuovo Cimento			3								1	2		**6**	**26,1%**
Phys. Rev.					2	1	1	2	1				2	**9**	**39,1%**
Rev. Sci. Instrum.												1		**1**	**4,3%**
TOTAL	**2**	**1**	**4**	**1**	**2**	**1**	**1**	**2**	**1**	**1**	**2**	**3**	**2**	**23**	**100%**
%	**8,7%**	**4,3%**	**17,4%**	**4,3%**	**8,7%**	**4,3%**	**4,3%**	**8,7%**	**4,3%**	**4,3%**	**8,7%**	**13,0%**	**8,7%**	**100%**	

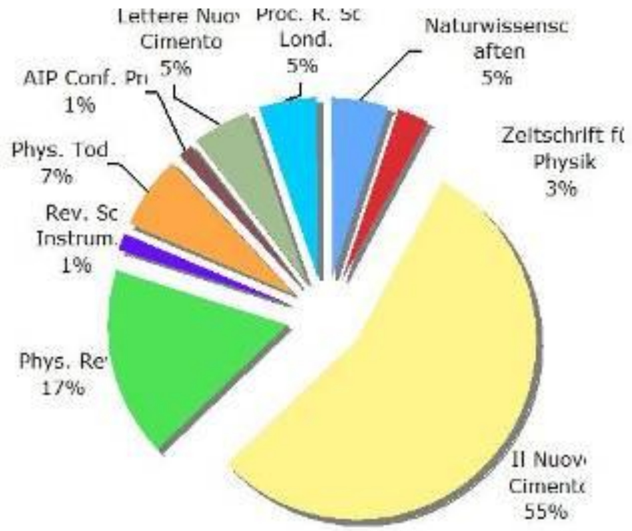
PARTICLE PHYSICS	1950	1951	1952	1953	1954	1955	1956	1957	1959	1960	1961	1963	1970	1973	1977	TOT.	%
Naturwissenschaften					1											**1**	**3,7%**
AIP Conf. Proc.														1		**1**	**3,7%**
Il Nuovo Cimento	2		1	2	5	1	2	1	1	1	1	2	1			**20**	**74,1%**
Phys. Rev.		1					1	1								**3**	**11,1%**
Lettere Al Nuovo Cimento															2	**2**	**7,4%**
TOTAL	**2**	**1**	**1**	**2**	**6**	**1**	**3**	**2**	**1**	**1**	**1**	**2**	**1**	**1**	**2**	**27**	**100%**
%	**7,4%**	**3,7%**	**3,7%**	**7,4%**	**22,2%**	**3,7%**	**11,1%**	**7,4%**	**3,7%**	**3,7%**	**3,7%**	**7,4%**	**3,7%**	**3,7%**	**7,4%**	**100%**	

It's possible to note that the articles written by Amaldi on Nuclear Physics started in 1932 and ended in 1947, with a total number of 23; likewise, the articles published by Amaldi on Particle physics started in 1950, just after the end of the previous articles, and ended in 1977, towards the end of his scientific career. The total number of articles in this case is 27, a number very similar to the previous. The articles referred to the first topics are scattered over a period of 15 years (in particular in the first 10 years, from 1932 to 1941), while the second topics are scattered on a more wide range: 27 years. The same analysis is made in the other case.

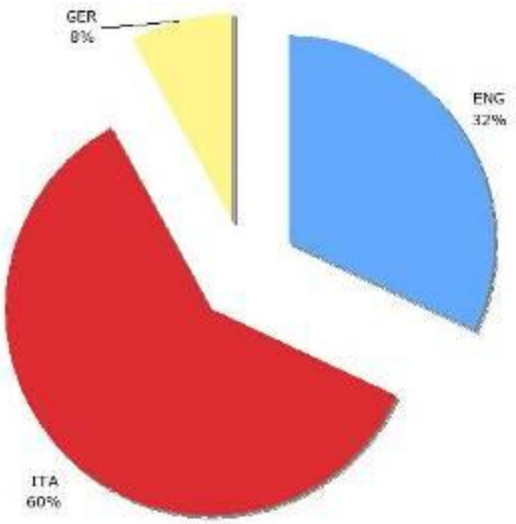
* * *

To end, I'd like to propose a further reading of the articles written in the indicated period. Always in the case of Amaldi, but also in all the other, it is possible to read the number to underline the correlation between the rate of articles and the magazines, and also the rate of articles and its language. In the first case the result can be summarized in a table with the corresponding graphics:

MAGAZINE	N art.	%
Naturwissenschaften	4	5,3%
Zeitschrift für Physik	2	2,7%
Il Nuovo Cimento	41	52,7%
Phys. Rev.	13	17,3%
Rev. Scient. Instrum.	1	1,3%
Phys. Today	5	6,7%
AIP Conf. Proc.	1	1,3%
Lettere a Il Nuovo Cimento	4	5,3%
Proc. Royal Soc. London	4	5,3%
TOTAL	**75**	**100%**



Number of articles by magazines.



Number of articles by speech areas.

There is a wide range of magazines chosen for the publications, with a clear predominance of *Il Nuovo Cimento*. Grouping the data by linguistic areas, there is a predictable predominance of the Italian language, and a good rate also for the English language. German is due to the use of the Rome group to publish in Italian and German. But this use changed after WW II.

WRITING THE HISTORY OF THE PHYSICAL SCIENCES AFTER 1945

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 773.

MEMBERSHIP OF CERN AND THE EUROPEAN SCOPE OF SPANISH PHYSICS[1]

Xavier ROQUÉ
Centre d'Història de la Ciència (CEHIC), and
Departament de Filosofia, Facultat de Ciències, Universitat Autònoma de Barcelona, SPAIN
xavier.roque@uab.cat

Abstract

Spain joined CERN on 1 January 1961, to withdraw seven years later on financial grounds. Building on the CERN archives, this paper deals with Spain's first membership of CERN as seen by the physicists and diplomats that handled membership. Beyond the lack of political will and the economic burden that are usually blamed for Spain's withdrawal, I argue that there were "failures of communication" between CERN and Spain, that became apparent in the recruitment of staff, the tender of contracts, and the contribution of member states. Politics and economics were not solely responsible for withdrawal: the long-term R+D policies of Franco's regime, as well as the research outlook of scientists and policy makers such as J. M. Otero, need to be taken into account.

Spain became a member of the European Organization for Nuclear Research (CERN) on 1 January 1961. CERN had been created in 1954 by 12 European countries with the avowed aim of pursuing particle physics research. Spain withdrew in June 1969 with effect from 31 December 1968, to join again in 1983, under the first socialist government of democratic Spain. In spite of its significance for any understanding of research, science policy and international relations during Francoism, Spain's first stage at CERN has claimed little historical attention. The three-volume *History of CERN* reflects the nearly negligible impact of Spanish membership in the 1960s: "Spain" first appears in vol. 2 as a country "hardly represented at Geneva in the mid-1960s", and is listed in vol. 3 as one of the countries that abstained on the new convention in 1967.[2] Spanish high-energy physicists have portrayed the episode as "a paradigmatic example of erratic governmental

[1] Research for this paper has been supported by the Spanish Ministry of Education through project HAR2008-05039/HIST "Bases para una historia de la física en España en el siglo XX". I acknowledge permission to access and quote from the CERN Archives, Geneva (Switzerland), and thank Anita Hollier, CERN archivist, for her assistance; unless otherwise stated, archival references are to files in the CERN archives. I also thank participants in the simposium "Writing the history of the physical sciences after 1945", particularly John Krige, for their comments.

[2] See D. Pestre, "The CERN system, its deliberative and executive arms and some global statistics on how it functioned", in Armin Hermann, John Krige, Ulrike Mersits and Dominique Pestre, *History of CERN. Vol. 2, Building and running the laboratory* (Amsterdam; Oxford: North-Holland, 1990), p. 341–415, on p. 409: "Austria, Denmark, Greece, and Spain […] were hardly represented at Geneva in

policy". They reckon that diplomacy, rather than scientific research, was the main reason to join, and agree with the official line that the mounting contribution made withdrawal inevitable. Even though "membership clearly had a positive scientific impact", it was "badly planned and nothing was done to take advantage of it".[3]

One important work has implicitly challenged the physicists' account. Building on the archives of the Spanish Ministry of Foreign Affairs, Ana Romero de Pablos and José Manuel Sánchez Ron have provided evidence of the Spanish government commitment to the organization through the 1960s. Central to their account is the Spanish candidature for the site of new 300 GeV Super Proton-Synchrotron that CERN started to plan in 1964, and finally built in Geneva. In June 1966, a commission including chairmen of industry, high-rank officials, diplomats, scientists and an embedded journalist, campaigned in CERN for the Spanish site, a visit that was well publicized in the Spanish press. Franco's cabinet came to be split on the candidature: an ad hoc ministerial Commission recommended in September 1967 to remain in CERN as long as the new accelerator was built in El Escorial; for the Ministry of Foreign Affairs, membership was not to be conditioned by the decision about the site; and the Ministry of Finance pushed for withdrawal whatever the case. Romero and Sánchez Ron finally endorse the view that the Spanish economy could not bear the burden of membership.[4]

In this paper, I bring to this story previously untapped sources in the CERN archives. I deal with three prominent issues that had to be balanced against each other: the contribution of member states, on the one hand, and the recruitment of staff and the tender of contracts, on the other. I am concerned with the tacit cultural assumptions that underlined the relations between the Spanish physicists and their European counterparts, and reflect upon their significance for the regime's take on science and technology.[5] Spain's membership entailed high political stakes: it was mediated by the Spanish Nuclear Energy Board (*Junta de Energía Nuclear*, JEN), a governmental agency created in 1951 and presided by Franco's head of general staff and Minister of Air Force, Juan Vigón Suerodíaz (1880–1955). Vigón was succeeded by Navy engineer José María Otero Navascués (1907–1983), a key figure in the reconfiguration of physics in the decades following the Civil War (1936–1939), as the regime sought to enlist modern science in the construction of a totalitarian state based on a national-catholic tradition.[6] Physics and the nuclear sciences became a tool of international legitimation and national pride under military control. What effect, if any, did this reactionary modernist background have on Spain's first stage at CERN? I will argue that Spanish diplomats, together with scientists qua policy makers such as Otero, did not lack political will, but dealt with CERN in terms of national quotas while paradoxically acknowledging this was not the way the organization was run. Ultimately, their institutional and (in Otero's case) personal strategy, rooted in the autarchic policies of early Francoism, did not pay off with CERN the way it had with other international organisms.[7]

Costs: the contribution of Spain

Spain's contribution to CERN hovered above 50 million peseta (some 2.7 million Swiss franc, around 4 % of the organization's annual budget) between 1961–63. Spain had also paid an initial special contribution of 2.7 million Swiss franc, down from 6.9 million (a 61.2% rebate).[8] In 1963, the Spanish Delegation submitted a proposal to mend the method of calculating the contribution of member states, to take into account the national income per capita, rather than gross national product, and the stage of scientific and industrial development of each member. This prompted a revision of the criteria used as a basis for the calculation of contributions, which were compared with the criteria of other intergovernmental organizations. However, international statistics were "very incomplete" and had not been collected on a comparable basis; moreover, some doubts persisted "about the exact meaning of 'scientific research'".[9] The Finance Committee of CERN discussed in great detail the economic situation of Spain, building on data gathered from the International Monetary Fund and the United Nations, and complementary information on the expenditure on education and research supplied by the Spanish government. The Committee noted that "the first comprehensive study of research expenditure in Spain was made in 1963 in connection with the preparation of the Development Plan" and that there were "no comparable data for previous years". According to the figures provided by the Spanish government, the expenditure on research and development was 1,513.8 million peseta, which were very unevenly distributed between basic research (164 million, 10.8%), applied research (719 million, 47.5%), and development (630.8 million, 41.7%). The distribution by scientific and economic sectors showed the importance granted to Nuclear Energy, Biological and Agricultural Research, and Geology and Mining, which together got 712 out of 1,194 million peseta (2/3 of the expenditure).[10] In December 1963, the CERN Council granted reductions in the Spanish contribution of 50% in 1964, 35% in 1965, and 20% in 1966.[11]

In 1966 Spain asked for a 35 per cent reduction of its contribution over the next triennium, arguing that it would otherwise contribute 7.1 per cent of the country's research and development annual budget (some 35 million dollar, or 0.2 % of its GDP) to CERN alone. The Finance Committee was not willing to adopt a formula to calculate reductions on the basis of national income per capita, such as the UN formula $1/2 \cdot (1000 - x)/1000 \cdot 100$ —where x stands for average national income in US dollars, and which results in 28.2% for $x = 436$ USD, Spain's average income for 1962–64— and instead recommended to follow an ad hoc procedure. The Council finally approved a reduction of 20% for the triennium 1967–69, but even this proved untenable, and in a matter of months Spain was asking for a 28% reduction, implicitly referring to the UN formula.[12] In the final round of negotiations one year later, after Spain had notified its intention to withdraw from the organization unless a "substantial reduction" for the coming five years was granted, the Council decided to accord a reduction of 50 % in the Spanish contribution for the next three years.[13]

While existing accounts suggest withdrawal was a clear-cut decision, the CERN archives actually show it was a protracted affaire. In December 1968 Spain asked the notice of withdrawal to be kept in abeyance and "to remain 'de jure' a member of the Organization, whilst accepting not to exercise her rights". The letter reached CERN too late to be discussed at the 40th Session of the Council, which received it "with great satisfaction", and a decision was postponed until the 41st Session; in March 1969, rising Spanish theoretical physicist Pedro Pascual was "quite optimistic" the situation could be reversed. But a couple of weeks before the Council session of June 1969, Spain communicated its final decision to withdraw with effect from 31 Dec 1968 "due solely to economic and financial reasons".[14]

Benefits: staff and contracts

Contribution meant little in itself: beyond its huge symbolic value, the cost of belonging to Europe's leading scientific organization had to be gauged against tangible benefits, including staff and contracts.

Used to share in international organizations as a national representative, Otero thought that Spanish physicists and engineers had to be hired on the principal basis that Spain was a member of CERN.[15] His views run against the organization's policy, which placed professional skill and scientific achievements over nationality. Tensions came to the fore quite soon, and they paradoxically involved CERN's first and higher-rank Spanish staff physicist, Rafael Armenteros (1922–2004), an Spanish exile who had graduated in Physics at Imperial College in 1946. In December 1960, just a few days before Spain became an official member, Armenteros was offered a job at CERN. The problem with Armenteros was not just his Republican past, but also that Spain wanted to have a saying in the recruitment of her nationals. The *Delegado Permanente de España cerca de las Organizaciones Internacionales*, José Manuel Aniel-Quiroga, even suggested that staff members whom they did not regard as Spaniards (i.e. holders of a valid passport) should be listed as 'stateless', clearly referring to Armenteros.[16]

Shortly after joining the organization, and following a suggestion by the Director-General, J. B. Adams, that two or three physicists visit CERN "to study the work going on at our Laboratory and the way in which other Member States collaborate with us", Otero set up a delegation "to discuss the possibilities for Spanish personnel to join the CERN".[17] CERN had meanwhile advertised posts for engineers, physicists, mathematicians and operators in the Spanish press; even though the Spanish Ministry of Work had approved the insets, Otero was not pleased that the JEN had not been told, and asked CERN's president Jean Willems not to take any decision until the Spanish commission had visited CERN.[18] In his report about the visit by the Spanish delegation, Samuel A. Dakin, CERN'S Directorate Member for Administration, noted that "we had none of the anticipated trouble, in the sense that they did not take up the question of methods of recruitment, nor make any mention of Armenteros, except to inquire whether he was yet in post. But they had obviously come with an extremely clear and firm idea as to what Spain was going to get out of CERN, which was at this stage a suitable training for as large a number of her scientists as possible… They reiterated these suggestions after they had made a round of Divisions, when apparently they found a good deal of interest in some of their possible candidates, I presume mainly on the assumption by the people they spoke to that the Spaniards would be fellows or would come outside existing staff ceilings… We promised them nothing, emphasized the competition for fellow and staff posts, but said that we would do what we could to meet the situation".[19]

Later that year Otero expressed his views that Spain's "economic sacrifice" should be rewarded with a group of researchers belonging to CERN's staff, and put forward a senior Spanish physicist for a permanent position. Director-General John B. Adams told Willems that the candidate's experience was "not sufficient in high energy physics to justify a grade which would be acceptable to him", and instead offered a "visiting scientist" position although "he hardly qualifies scientifically for this position". His judgement was based on an appraisal by G. Bernardini: "[the candidate's] papers show a standard physicist. Some of them are approaching technical problems rather lightly, others give the impression of a disproportion between amount of work and data and conclusions derived from them". Adams thought a point could be stretched in this case as long as it was not taken as a precedent, and Willems' final answer was very carefully worded so as to make the post appealing to both Otero and his man. I take this exchange to be extraordinarily revealing of the rather different views on recruitment and scientific excellence held by Otero and CERN's scientists and officials.[20]

The issue was taken up over and over again in the following years, both parts being concerned about the "disproportionately small" number of Spanish staff at CERN. Over the first 18 months of membership, about 40 Spanish candidates were called to selection boards, but the JEN's focus on applied nuclear sciences appears to have backfired, because "although many of the Spanish candidates have experience in nuclear physics or engineering, this is very commonly in reactor work which has little application to the sort of work we do here". By October 1962, however, there were eight Spanish staff members, including 4 scientists or engineers.[21] By mid-1963 the situation of Spain was not unlike that of Sweden, a founding member of the organization, which contributed 4.18 % of the budget (as compared with Spain's 3.36 %)

García González (Mechanical Engineer grade 9); and J. Goñi Unzué (Physicist grade 9). See also Otero to Weisskopf, 5 Sep 1962 (DIR-ADM-PERS-02).

and had 13 members of staff, including so-called supernumeraries (as compared with Spain's 16).[22] Spain tried all along, with limited success, to retain some control of the recruitment process, having potential candidates send their CVs to the Spanish Ministry of Foreign Affairs or the Spanish Institute for Emigration, rather than to the organization itself, as was usually the case.[23]

Together with staff underrepresentation, the lack of contracts with Spanish companies played also a role in the decision to withdraw from CERN. How were these seen from the inside, as far as CERN sources allow us to tell? "Failure in communications" between CERN and Spanish industry was suggested by S. Dakin and rejected by Otero.[24] The results of Spanish firms were certainly disappointing: by 1965 they had been awarded contracts for 25,545 Swiss franc, a negligible percentage of the 452 million Swiss franc total of contracts awarded between 1952–65. However, firms in other countries did not fare much better. CERN's policy was based on "competitive tendering" (whereby firms were invited to submit offers), rather than "just return", but there was a gulf between principle and practice: not all contracts were competitive, and submitting an offer was a costly process that was not compensated if the firm failed to win the contract. As J. Krige has shown, the process was not completely rational nor objective, but it was maintained mostly for political reasons, as it represented "an agreement between the member states that no consistent effort be made to distribute contracts between them in relation to their contributions to the budget. The *practical implications* of the 'competitive' policy are thus best understood *negatively*, as meaning that there is no policy of just return in the award of contracts for plan, equipment, and supplies".[25]

Conclusion

Sources at CERN provide a new perspective on Spain's first membership of the organization. Political will was not lacking, but was rather rooted in autarchic practices and attitudes. National representation had granted Spain a place in many an international organism and provided a Navy engineer such as Otero with scientific credentials. Quotas had effectively worked in many instances and would work with the European Space Research Organization (ESRO), which Spain nearly left at about the same time; but they did not work with CERN, which was run on different principles. Otero's loss of influence within the Spanish R+D system by the mid-1960s, as new governmental agencies were created and young, competent physicists were occupying university chairs, may also have played a role.

BERTRAND GOLDSCHMIDT AND ATOMIC TECHNO-SCIENTIFIC DEVELOPMENT IN POSTWAR FRANCE

Matthew ADAMSON
McDaniel College Budapest, HUNGARY
mhadamson@mcdaniel.hu

Abstract

This paper considers the role of biography in the writing of the history of the physical sciences in the postwar, and in particular the history of techno-scientific institutions. It focuses on radiochemist Bertrand Goldschmidt, who played an important role in determining the nature of the Commissariat à l'Energie Atomique's development despite the fact that he was not a policy maker. Rather, as a radiochemist who chanced to specialize in the chemistry of plutonium, he discovered several scientific and non-scientific means to encourage its production in France, and thus influence the general military orientation of the French nuclear program. Goldschmidt was a prolific memoirist and participant-historian, and a look at his writings reveals a noticeably supple view of the postwar nuclear world, despite the narrowness of his technical specialty and the nationalist orientation of the CEA. A similarly broad view is exhibited in the writings and interviews of Goldschmidt's fellow CEA chemist, Jules Guéron. However, for several reasons, Guéron's interests did not influence the CEA's development as did Goldschmidt's, and in fact Guéron left the CEA to become Euratom's first director of general research. This paper suggests that biographical studies incorporating oral histories alongside institutional archives can present a means for framing the development of postwar techno-scientific institutions, and are interesting stories in and of themselves.

Introduction

This paper concerns some aspects of the life, work, and views of Bertrand Goldschmidt, the French radiochemist born in 1912, 33 years old when World War II ended. It explores the role of biography in the writing of the history of the postwar physical sciences. This role is an interesting and complicated one when considered in the light of politically sensitive techno-scientific systems, especially those involving nuclear energy. And this role becomes all the more interesting when one discovers that the actor in question was publicly pronouncing on the state of affairs in the field.

The present study focuses in particular in the earliest postwar years of Goldschmidt's scientific life, tracing aspects of it to the early 1950s, when Goldschmidt became involved in encouraging a French atomic bomb program. Goldschmidt's story is representative of the times. He was a living example of the global reach and nature of postwar atomic science. In the first six months of 1946 alone, on missions related to science, he was all over the map: Chalk River and Ottawa; London and Paris; Washington, New York and San Francisco; the Bikini Atoll. And, like many other postwar scientists, he played a remarkable number of roles (which he for one eagerly sought): radiochemist, engineer, manager, diplomat, government advisor, public educator and propagandist, political observer, a probe to gather as well as give away information. He shared a sense with many other scientists in the atomic field that there were closely associated fundamental shifts in science, technology, politics, and war that could best be understood from a historical perspective and with a scientific background.

Goldschmidt's most important role of all: plutonium specialist, *the* French plutonium specialist. One should briefly review Goldschmidt's background to see how he became one. From a wealthy Parisian Jewish family whose eldest son entered the Ecole Polytechnique, Bertrand Goldschmidt himself entered the Ecole de Physique et Chimie Industrielle (EPCI) in Paris, in 1930. From there, like EPCI graduate Frédéric Joliot, Goldschmidt went not into industry, but to the Radium Institute. He was Marie Curie's last personal assistant.

Goldschmidt completed his doctoral thesis in 1939, and began to teach in the Paris science faculty. After the German occupation of Paris, he managed to get to the unoccupied zone, and then in 1941 escaped France for the US. Eventually, it was arranged for him to join the British Department of Scientific and Industrial Research. It was under these auspices that in July 1942 he was sent to Chicago, to the Met Lab's Chemistry Section, where Glen Seaborg's team was studying the chemistry of plutonium. According to Seaborg's diary, Goldschmidt quickly fit in and was invited into the leadership circle planning laboratory activities. By the end of October, however, Goldschmidt was gone, sent out of the American facility, eventually to join a new Anglo-Canadian team in Montreal. It was in this team, in 1945, that he carried out his first independent work on plutonium: the discovery of a new method of plutonium separation involving the solvent triglycoldichloride.

By the end of 1945, the Anglo-Canadian team had managed to complete an experimental heavy-water reactor and to launch the construction of Canada's first large-scale reactor at Chalk River. Heading back to France from it were not only Goldschmidt, but also Jules Guéron and physicist Lew Kowarski, all deeply involved in its activities, and profoundly changed by their wartime experiences. From the first days of the French atomic program, they earned the ironic label "Canadians", a historic recognition of the techno-scientific expertise they were bringing from the New World to the Old. It should also be noted that three of the French scientists in Montreal, Guéron, Goldschmidt, and Pierre Auger, broke oaths of secrecy to the Anglo-Allies in order to inform Charles de Gaulle about the top secret American bomb project. They were concerned that De Gaulle knew what his British and American allies were up to in order to deal with them rationally; and, a more deeply felt belief, they were convinced that the bomb, and other atomic technologies, were of such importance that the most significant Frenchman of the moment ought to be prepared to see his own country's entry into the atomic world as soon as the opportunity allowed.

Finally, it must be noted that Goldschmidt's view of the new atomic world was as informed by the events of 1946 as by the war. Goldschmidt was repeatedly distracted from his duties in France's Commissariat à l'Energie Atomique (CEA) by his service as a technical advisor to the French United Nations delegation involved in the forlorn attempt to negotiate an international agreement on atomic energy. And in May, he learned that he had been appointed to serve as a French observer at the Bikini atomic tests, taking him away from France for more than two months.

By the beginning of the following year, he had a fully-formed view of the atomic world that he would elaborate over the rest of the decade.

Goldschmidt's atomic worldview

He conveyed his view in public lectures, which he gave to many audiences with evident pleasure for years to come. His message consisted of several overlapping elements, familiar to historians: the themes of the Federation of American Scientists, "no secret, no defense, international". But his own message was not merely an echo of theirs. It contained skillfully chosen details; it was personal; and it sought to describe a view of the atomic world from France, more often than not for French audiences.

It began with the atomic bomb, and its destructive power. Some of what Goldschmidt relied on were popular explanatory devices, like the devastation of Paris by a hypothetical atomic bomb exploded above the Place de la Concorde.[1] He also stated with eloquence the consequences of an atomic war, where atomic bombs might (this comes from 1949) "wipe out…in one blow our cities, our centers full of human lives, from which originate and return all of the links that at present organize our country".

We should not underestimate the effect that witnessing the Bikini tests had on Goldschmidt, even if he did not frequently describe the blasts themselves in his public lectures. When he did, the turn of phrase could be dramatic, and pointed. About the second, underwater explosion, he said to Université radiophonique international listeners in 1949: "The

Goldschmidt M4.13.37, M4.13.38, & M4.13.40. Due to restrictions in the length of this publication, certain details are not cited; please contact the author for page numbers, etc.

water falling back down on the ships from two kilometers high was so full of radioactive particles that the ships would have become veritable radioactive crematory ovens for the crews, had they been there." The immediate military consequences were clear: a D-Day amphibious landing was no longer possible. When he said that in the atomic age naval warfare must be dominated by the submarine, he could easily have had images of the shattered surface fleet at Bikini in his mind.

The essence of the situation as Goldschmidt came to describe it was more than just that "the atomic weapon must render…armies, navies or fortifications outdated", but that it must do so to "war itself". All orthodox military defenses were hopeless (May 17, 1946, Sorbonne.). Only dispersion of forces, and in fact of entire populations, would counter the effects of atomic weapons (Ecole Normale d'Administration, July 8, 1947.). And that was a political act, making the discovery of fission, not really a military, but a political phenomenon, "the most important political factor of our day leaving the laboratory for the foreign departments of all great nations". (Columbia University, May 1947.) Goldschmidt often qualified his remarks as those of the non-specialist: To an audience at the Ecole Normale d'Administration he apologized, "you will excuse me for presenting to you my personal views, that is, those of a chemist and not of a specialist in foreign affairs." The qualification gave him neutral ground to make public statements about global politics. At the same time, his expertise as an atomic scientist gave him the technical understanding necessary to understand the new technological forces influencing the globe, and in his view one must start with the former to get to the latter. And, over and over, for years, the message he chose to deliver was a fundamentally political one, best summed up by the title of the book he proposed to the CEA be translated into French: *One World Or None* (in his rendering: "Le monde sera unifié, ou ne sera pas."—ENA, February 16, 1948). Perhaps it is not surprising that Goldschmidt admitted a great deal of admiration for the Acheson-Lilienthal report, and told an American audience that the French atomic scientists around him did as well.

One thing Goldschmidt told all audiences was that when it came to the bomb, there was no secrecy. Early on, this came with rather clichéd phrasing: "There is no secret about the atomic bomb. The fundamental scientific facts were published and known since 1939; we all know the biggest secret, that the bomb works" (Sorbonne, May 17, 1946.). But the examples with which Goldschmidt illustrated the point indicate both the ingenuity of his argument against secrecy and the personal scientific experience he was drawing on. Goldschmidt noted when in the American Senate the question of secrecy was raised, one witness testified that, when the Americans cut off information to the British, their team in Canada developed a simpler, more complete method of plutonium separation —Goldschmidt's triglycoldichloride. Goldschmidt's view was that the only secrets to speak of were industrial secrets that enterprising countries could arrive at sooner or later (ENA, July 8, 1947).

Just as he believed the American policy of secrecy was mistaken in its conception, he also assumed that it would not work, and sooner or later the Russians would build their own bomb. The first instance of him offering a prediction is from July 1947, at the Ecole Nationale d'Administration.: "in five years perhaps, in fifteen or twenty years surely…" In his view, the American invention had given them a dramatic advantage in world affairs at the end of World War II; the Russian acquisition of the bomb would not lead to equilibrium, but rather a Russian advantage, due to the vulnerability of America's urban concentrations.

As for France, from the summer 1946, Goldschmidt could report that at the UN the French had declared the peaceful intentions of its new atomic program. CEA representatives, Goldschmidt included, qualified that declaration by putting it in the context of the CEA's own meager resources, inadequate for a gigantic atomic bomb program *a l'américaine*. The CEA's interest was, Goldschmidt said, in the production of electricity. He explained to energy-rich Americans at Columbia University in 1947 that in France it would be a blessing to have atomic energy "in regions where the lack of coal is so bitterly felt". Goldschmidt also often mentioned radioisotopes, and even alluded to using radiation present in reactors for genetic modification (Société des Ingénieurs Civils, March 18, 1949).

This view of the atomic world —Goldschmidt's understanding of No Secret, No Defense, International, and even his enunciation of France's declaration before the UN, did not automatically mitigate the possibility of French atomic weapons. To the contrary: in the right circumstances, it could lead the plutonium specialist to consider them the best option for his country.

One must take a moment to consider why Goldschmidt spoke out his view of atomic energy and its consequences to so many different audiences —from France, to Canada, to the US, from university lecture halls to military colleges and civil engineering societies. First, it was his job. Since in particular he was one of the few CEA scientists who had been involved in atomic projects in North America, and since he was one of the three of them working full-time for the CEA (the others being Kowarski and Guéron), he was called upon by various French institutions and civic groups to introduce them to atomic science, technology, and politics. This was especially so after Bikini.

But perhaps the most important reason of all why Goldschmidt took up, and never abandoned, public explication of his view of the atomic world, becomes clear when we examine what he said in 1949 —the year a CEA team led by him purified several milligrams of plutonium. It was in plutonium that Goldschmidt found his strongest public identity and voice. And he seems to have derived great enjoyment from explaining his view of why plutonium was interesting, and why it mattered.

Goldschmidt could not resist describing the incredible difficulties involved in the industrial-scale separation of plutonium. In this Goldschmidt was not just a self-identified plutonium specialist, interested in its industrial-scale production. He was an industrial alchemist. Even before any plutonium had been separated in France, he announced on French radio, "We have entered the era of industrial-scale transmutations" (French radio, March 5, 1949.). A few months later, when the time came to announce his team's success in such transmutations, he returned to the radio to answer a reporter's questions. Goldschmidt's response to a question about plutonium's importance and interest mixed the historical and practical:

> Plutonium's interest resides in the fact that it is a new element that does not exist in nature, and is a creation of man and of the 20th century…..plutonium is a nuclear fuel far more concentrated than uranium and will be the fuel used in future energy-producing atomic machines.

Goldschmidt then told his interviewer that his team of radiochemists had become "the first French alchemists" (French radio, November 23, 1949).

The product of the CEA's alchemy was not gold, but no matter. According to Goldschmidt, it would be the future measure of wealth and power. His March 5, 1949 rendering deserves to be quoted in full:

> Although the first element produced in quantity by modern alchemy might not be gold, this new element, plutonium, will be for the next few decades the sign of power and wealth of the states who possess it, at least if nations are based on a unified world, before the menace this same plutonium represents (French radio, March 5, 1949).

Goldschmidt, then, could judge his own importance to his native country in the light of its plutonium production.[2] He told his radio audience that the ease and speed with which countries could develop "a substantial breeding program" would be the principal markers of atomic energy development (French radio, March 5, 1949). And, he said, the success of such a program depended on the percentage of plutonium recovered from fission products (Société des Ingénieurs Civils, March 18, 1949). His technical roles in the French program were bookends to the entire system. Goldschmidt was responsible for overseeing the production of metallic uranium for reactors; and he was responsible for maximizing the efficiency of the plutonium recovery process.

The uses of plutonium

But for what would France use the plutonium Goldschmidt was so intent on creating?

In 1950-51, the CEA entered a period of crisis. In April 1950, the government dismissed High Commissioner Frédéric Joliot-Curie. Then, in August 1951, his administrative counterpart, Administrator General Raoul Dautry, died suddenly. The CEA was leaderless and rudderless, and its development and early postwar expansion were in doubt.

The crisis in the CEA, along with the Soviet bomb, led to detectable changes in Goldschmidt's assessment of the atomic world. Goldschmidt began to describe the duality of the French atomic program. He had done this implicitly before, in discussions of plutonium. He noted in 1947 that despite the short-sightedness and apparent avarice of the American secrecy policy, the US should not be accused of "extreme egotism", because, after all "nuclear fuel can serve indifferently to produce energy or make bombs" (ENA, July 8, 1947). Now he could apply the point to the French program, which he did on March 13, 1951, significantly at the Institut des Hautes Etudes de Défense Nationale:

> [O]ur Châtillon pile of a few kilowatts, which produces a few milligrams of plutonium per day, and the one at Saclay which will be about a thousand kilowatts and consequently produce about a gram of plutonium a day, are the indispensable steps to the study and construction of a powerful pile, which might be for military or peaceful goals. The plutonium that we isolated at the factory at Le Bouchet is certainly a nuclear explosive, it is peaceful only by its weight, currently 10 milligrams.

To this Goldschmidt added a pithy historical observation about technological development. Twelve years after the discovery of fission, tens of thousands had been killed, entire cities and fleets of retired warships destroyed, and hundreds of international meetings had been held, but atomic energy "has not yet turned the slightest steam turbine, the littlest electric motor".

---

[2] Notably, Goldschmidt categorized not only nations but reactors according to plutonium. Experimental piles produced quantities of plutonium on the order of a milligram a day; "medium power" piles made a gram of plutonium a day; and "high power" piles made hundreds of grams a day. To be fair, Goldschmidt added kilowatts to plutonium production: experimental piles approximately a kilowatt, medium-power piles about a thousand kilowatts, and high-power piles hundreds of thousands of kilowatts. Nevertheless, he is the first observer I have come across who classified *all* reactors according to their potential plutonium production (Société des Ingénieurs Civils, March 4, 1949).

At the same time, Goldschmidt also continued to qualify France's aging declaration before the UN, with ever more contortions: "we announced officially in 1946…that we did not have the intention to participate in the atomic arms race from the military point of view, because even if we had the intention to do so, it would not have been very sensible since our effort would only have been 1 to 1.5 percent of the American effort." And he remarked that the British, whose ambitions to produce electric power he admired, and whose program was on a much smaller scale than the American one, were now likely to make a bomb (ENA, October 27, 1951).

Proliferation worried Goldschmidt. It was not just the Russian bomb, though that was worrisome enough. He had already established that any country without a bomb was at the mercy of those who had it: "The factors that hitherto served to establish the hierarchy of military powers (strategic situation, industrial potential, number of men) must now be considered according to the possession or non-possession of the atomic weapon. The only security that exists for less powerful peoples is the will of those who have this weapon." In addition, a country with a hundred bombs could knock out one with a thousand —and any country, overexcited and trigger-happy, could launch a bomb that could start a general war (Sorbonne, May 17, 1946). And as Goldschmidt noted later, one might not even know where the bomb had come from!

Goldschmidt admitted that he could not predict how the French atomic program would fare. He expressed enthusiasm for a European collaboration if France led it; but that collaboration had not been forthcoming. And he admitted as well that he was not sure how successful France's efforts at uranium prospection would be (ENA, October 27, 1951). In Goldschmidt's view, there was increasing uncertainty in the atomic world, and in atomic France.

At just this time, the most important change in the history of the CEA was set in motion. The death of Dautry had created a vacuum that was energetically filled by the young Secretary of State for Atomic Energy, Félix Gaillard. At the beginning of September, Gaillard ordered the CEA's steering committee to formulate a five-year plan that would necessitate vastly increased budgets: the CEA must in a concerted fashion commit itself to a major, long-term goal. By the end of October the committee had the draft of a plan. Its defining feature: an output of kilogram quantities of plutonium by the end of five years.

The plan could hardly have been conceived without the presence in the CEA of Goldschmidt, and over the following four years, Goldschmidt performed several tasks essential to carrying the five-year plan out: identifying the best solvent for the extraction of plutonium (tributyl phosphate), supervising the construction of the plutonium purification pilot plant (by mid-1954 it was treating dozens of irradiated slugs), and choosing the private enterprise for the construction of the full-scale plant (Saint-Gobain). Goldschmidt stepped aside only at the construction of the full-scale plant itself.

The CEA's five-year plan was a fulfillment of Goldschmidt's plutonium ambitions. But Goldschmidt did not limit his interest in plutonium to simply seeing to it that it be produced. He did all he could in his position to make certain it served as fuel in a French atomic bomb. This included providing estimates for the CEA of the expected time and cost of bomb-grade plutonium; sitting on secret bomb program steering committees; and keeping the military at arm's length when they threatened to intrude upon the CEA's own effort to create a bomb program.

His interests as a chemist-engineer-alchemist alone do not account for why he did this. We must make note of his view of the atomic world, and especially the changes it underwent in 1950-1951, the uncertainty mentioned above. The view Goldschmidt came to elaborate suggested that France was better off with the bomb than without it, and that the bomb was indeed within France's grasp, given time. This does not mean that his support of a bomb program was due entirely to this view. A skeptical observer might note that the new administrator general of the CEA, Dautry's replacement, wanted a bomb program; Goldschmidt could best advance his own career, by following in step. And perhaps this is one reason behind Goldschmidt's encouragement of a bomb program. But it is not, I think, the most important.

Conclusion

This brings us back to the question of scientific biography in the postwar.

This story illustrates one argument made for scientific biography in Thomas Hankins famous 1979 article on the subject: Goldschmidt's life appears to be an excellent 'unit' for studying science in certain contexts, especially the technological and global political ones. And it is a particularly apt example for the study of postwar *nuclear* science, especially as a means of organizing a narrative, of a career trajectory and a life before the public. But there is a need for caution. I do not wish to suggest that, as far as the French atomic bomb is concerned, Goldschmidt was The Indispensable Man. And I do not wish to exaggerate Goldschmidt's sense of individual identity; here we see Goldschmidt's public face in particular. And we should always bear in mind that he was part of the CEA. Its identity was his just as he contributed to its.

I should allow Goldschmidt himself a chance to finish. In 1957 he wrote his own brief biography (in the third person), which he supplied to the NATO Defense College where he was to lecture on international atomic affairs. In it, he listed his roles in the CEA at that time: "Director in Charge of External Relations", "French representative on the consultative committee responsible for making preparations for the second atoms-for-peace conference". And, Director of the Chemistry Department: "He is now Director of the Chemistry Department, and is responsible for the chemical cycle of uranium, the preparation of artificial radio-elements, and also, more especially, the extraction of plutonium, that difficult problem for the new modern alchemist." If nuclear histories often juxtapose geopolitics with the minutiae of national technological development, here is a way not just to tie the threads together, but to witness them fused in the form of an influential actor.

Abstract

Bruno Touschek, born in Vienna in 1921, graduated in physics in 1946 in Göttingen. Among his mentors there were leading scientists of pre-war physics, with whom he collaborated in maintaining alive scientific research during the war. In participating to the reconstruction of physics in Europe, he performed a crucial role in the development of post-war theoretical physics in Italy since mid 1950s. The experience established in participating with Rolf Wideröe to the building of the first European betatron in Hamburg during the war, and in collaborating to the designing and construction of a synchrotron in Glasgow during the late 1940s, as well as his deep knowledge of Electrodynamics, culminated, fifty years ago, in Touschek's proposal to construct a small storage ring for electrons and positrons in the early Spring of 1960, and, after a few months, the much bigger ADONE. The events which led to the approval and construction of AdA, the first matter-antimatter collider, in Frascati National Laboratories near Rome, and the Franco-Italian collaboration which confirmed the feasibility of electron-positron storage rings are recalled.
All this showed that electron-positron colliders could compete with traditional proton machines, proved the feasibility of a new physics and opened the way to higher energy and luminosity. The road to matter-antimatter collisions started in war ravaged Germany and culminated on November 11th, 1974, when the discovery of the J/Psi was simultaneously announced by Burton Richter and Sam Ting. It was confirmed three days later by ADONE, the Frascati Italian accelerator, and signaled the beginning of a new era in particle physics which eventually led to some of the most important discoveries of the Standard model.
Touschek's subsequent work on infrared radiative corrections as needed to extract meaningful physics from high energy electron experiments and his contribution to educate a generation of theoretical physicists to the importance and technical proficiency in resuming light quanta, has also been described. In order to understand

Bruno Touschek's role in the reconstruction and development of post-War European physics, we also outline his formation both as a theoretical physicist and as an expert in particle accelerators during the period between the time he had to leave the Vienna Staatsgymnasium in 1938, because of his Jewish origin from the maternal side, until his arrival in Italy in the early 1950s. The whole reconstruction has made use of only very recently published material, and especially of archival unpublished documents as well as previously unknown correspondence which include letters to Arnold Sommerfeld and to Touschek's family in Vienna from Italy, Germany and Great Britain.

WHO DISCOVERED QUARKS?

Martin COUNIHAN
University of Southampton, THE UNITED KINGDOM
counihan@soton.ac.uk

Abstract

Quarks are fundamental to our understanding of the universe. The devising of the quark model, its experimental confirmation, and its eventual integration into the "Standard Model" of elementary particles was one of the outstanding achievements of 20th-century physics. It is surprising, therefore, that confusion has arisen about how quarks were actually "discovered", i.e. how experimental evidence led the scientific community to accept the real existence of quarks. A myth has emerged that the existence of quarks did not become accepted until after 1968, and then primarily as a result of the deep inelastic electron-proton experiments at Stanford Linear Accelerator Center (SLAC) in California. This view was bolstered by the award of the Nobel Prize in 1990 to Friedman, Kendall and Taylor. The "SLAC myth" has been perpetuated in textbooks of physics, in Wikipedia, and elsewhere.

However, the contemporary literature shows that the existence of quarks was widely accepted well before 1968, mainly because of data from hadron-hadron scattering experiments using bubble chambers at Brookhaven (New York) and CERN (Geneva). The continuing harvest of such data into the early 1970s rendered the quark model practically unassailable. The SLAC data, while providing valuable complementary evidence, was of secondary importance for establishing quarks in the minds of most scientists at the time.

Suggestions are made about how the "SLAC myth" arose. Philosophical, political and nationalistic factors were surely involved. No doubt there was a desire for SLAC to publicly justify its costs and to distinguish its findings from what had already been revealed elsewhere by the bubble-chamber technique. When a major scientific development has to be conveyed to the public in just a couple of sentences, oversimplification is hard to avoid and a misleading myth may easily be generated.

Quarks constitute one of the greatest scientific triumphs of the later 20th century and are central to our present-day understanding of the microcosm. The quark model has been widely popularised and its essentials are now routinely taught, at least qualitatively, even at sub-university level. One would therefore hope that the story of the discovery of quarks would be well-documented, well-understood and accurately retold.

The work reported here was originally prompted by the feeling that the discovery of quarks is rather poorly dealt with in some of the textbooks and courses that are provided for students today. The topic is often covered very briefly, giving students only a sketchy outline of how the existence of quarks came to be accepted. Arguably, that doesn't matter –as long as they understand the physics of quarks, why worry about the history? But it appears that even the little history that students are taught is surprisingly biased, if not seriously distorted.

It is necessary to begin with a few philosophical remarks. Were quarks invented, discovered, or constructed? It is uncontroversial that the quark model, as a well-developed theoretical hypothesis, was put forward by Gell-Mann and by

Zweig in 1964. It was based on the earlier ideas of Gell-Mann and Ne'eman –the "Eightfold Way" of 1961– and of Sakata and, much earlier still, of Fermi.

The quark model provided the most natural physical explanation for the regularities of the otherwise-bewildering hadron spectrum. However, the experimental data available in 1964 was not sufficient to confirm or refute the quark model convincingly in the minds of all physicists. The discovery of the omega-minus hyperon at the Brookhaven Laboratory was announced in 1964, but it could be argued that it was a prediction of the Eightfold Way symmetry scheme, not of the quark model specifically. And, since quarks could not be isolated and observed as independent particles, scientists with a positivistic frame of mind could claim that the existence of quarks was unproven, and perhaps unprovable and therefore meaningless.

Nevertheless, within a few years the existence of quarks had become generally accepted among particle physicists on the strength of the extensive experimental observations which accumulated after 1964. The acceptance of the quark model on the basis of observational evidence is what is meant in this paper by the "discovery" of quarks.

However, according to another viewpoint, quarks cannot be said to have been "discovered" at all but should be regarded as a social construction, confected collectively by the particle physics community and bearing no necessary relationship to physical reality. Anti-realism had a significant impact on the historiography of science during the late 20th century: in the context of the quark model, Andrew Pickering's *Constructing Quarks: a sociological history of particle physics* (1984) was particularly prominent. Curiously, though, Pickering concentrated on the developments of the mid- to late 1970s (Cushing 1985 and Barlow 2000) as if that had been the time-frame during which quarks were "constructed". Certainly it was the time-frame during which experimental practice shifted overwhelmingly into lepton-beam and storage-ring experiments. It was also the time when the charmed quark became accepted as the explanation for the J/psi particle discovered at Brookhaven and at the Stanford Linear Accelerator Center (SLAC) in late 1974. But, by then, quarks had been widely believed in for the best part of a decade.

What are students taught about the discovery of quarks? In Britain, pre-university (A-level) students studying physics are expected to learn very little about the history. The common A-level specification (EdExcel, 2007) mentions "that nucleon structure can be revealed by high-energy deep inelastic electron scattering", alluding to experiments which took place at SLAC in the late 1960s; but it refers to none of the earlier experimental work.

The book by Tipler and Mosca (2004) is typical of the kind of voluminous, comprehensive and widely-used textbook that covers physics at an introductory and intermediate university level. According to Tipler and Mosca, "The great strength of the quark model is that all the allowed combinations of three quarks or quark-antiquark pairs result in known hadrons. Strong evidence for the existence of quarks inside a nucleon is provided by high-energy scattering experiments called *deep inelastic scattering"* (italics in original). And, "These experiments are analogous to Rutherford's scattering of alpha particles by atoms in which the presence of a tiny nucleus in the atom was inferred from the large-angle scattering of the alpha particles." Thus, Tipler and Mosca strongly suggest that the existence of quarks was accepted because of the evidence from deep inelastic scattering –evidence which only began to appear at the end of the 1960s.

As another example, one may look at Schiller's (2011) online textbook *Motion Mountain*, which says that "The prediction of components inside the protons was confirmed in the late 1960s when Kendall, Friedman and Taylor shot high energy electrons into hydrogen atoms. They found that a proton contains *three* constituents with spin $^1/_2$, which they called called *partons*. The experiment was able to 'see' the constituents through large angle scattering of electrons, in the same way that we see objects through large angle scattering of photons. These constituents correspond in number and (most) properties to the so called *quarks* predicted in 1964 by George Zweig and also by Murray Gell-Mann."

Much the same story may be found in Wikipedia, whose *Timeline of particle discoveries* gives, for the year 1969, "Partons (internal constituents of hadrons) observed in deep inelastic scattering deep inelastic scattering experiments between protons and electrons at SLAC; this was eventually associated with the quark model (predicted by Murray Gell-Mann and George Zweig in 1964) and thus constitutes the discovery of the up quark, down quark and strange quark."

This paper is not based on a comprehensive survey of textbooks, but the accounts given by Tipler and Mosca and by Schiller are typical, and it is clear that a myth has grown up about the discovery of quarks. The myth goes something like this: quarks were postulated theoretically in 1964 by Gell-Mann and Zweig because they provided a physical basis for the "Eightfold Way" symmetry which had been found to describe the hadron spectrum; and the theory was confirmed in 1968 and the succeeding years by electron-beam experiments at the Stanford Linear Accelerator Center (SLAC).

SLAC's own website certainly encourages this view: under *SLAC History* for the year 1968, it lists "First evidence discovered for quarks". And, of course, in 1990 the Nobel Prize in physics was awarded to Jerome Friedman, Henry Kendall and Richard Taylor "for their pioneering investigations concerning deep inelastic scattering of electrons on protons and bound neutrons, which have been of essential importance for the development of the quark model in particle physics."

But what really happened? Personal memory indicates that quarks were widely believed in within a year or two of the publications by Gell-Mann and Zweig, at any rate among the younger generation of physicists in Europe. It would be possible to show this by citing many papers from the period, but the point can be adequately demonstrated by one or two especially prominent examples. For example, the highly distinguished physicist Viktor Weisskopf presented in 1966 a set of lectures at CERN which show that the quark model was then already commonly accepted as the way in which the hadron spectrum should be understood. Such lectures were provided for young scientists and for non-specialists, and as such were not intended to express unorthodox or speculative ideas.

A year later a similar set of lectures was presented at CERN by the MIT physicist B. T. Feld (1967), *The Quark Model of the Elementary Particles*. Over 48 pages, Feld described the quark model in detail. Not only did he catalogue the success of the quark model in explaining the static properties of hadrons (masses and decay widths) but he also mentioned predictions for the ratios of cross-sections for the photoproduction of vector mesons, and also for elastic scattering amplitudes and total cross sections in hadron-hadron collisions, including the Johnson-Treiman (1965) relations. Between them, then, Weisskopf's and Feld's lectures demonstrate that "quarks" were common parlance among theoretical and experimental physicists by the mid-1960s, at least at CERN; and they were retailing knowledge and ideas which were well established at the time and well supported by the experimental evidence then available.

But what sort of experimental evidence was it? During the 1960s, new and improved accelerator technology was making it possible for hadron-hadron collisions to be investigated at increasingly high energies. It was the heyday of bubble chambers, for the invention of which, in 1952, Donald Glaser received the 1960 Nobel Prize in physics. Just as there was no serious competitor to the bubble chamber as an experimental technique at the time, there was no serious competitor to the quark model for explaining the properties of the plethora new particles and resonances that were revealed. Moreover, the quark model provided a framework for understanding the overall qualities of high-energy hadron collisions: the ratios of cross-sections; the slowly-increasing multiplicities of particles produced; the phenomenon of inelastic diffraction; the "leading particle effect"; and the general peripherality of such collisions by which the resulting particles were confined to relatively low transverse momenta.

The quark idea became deeply rooted in the thought processes of ordinary particle physicists. Physicists often used quark-line diagrams to represent interactions, and the "diagrammar" of the quark model could explain why, for example, there is a "duality" in two-body-to-two-body collisions, with hadron resonances being formed by the amalgamation of two colliding particles but also having virtual hadrons exchanged between them. Of course, the quark model was expressed quantitatively as well as qualitatively and diagrammatically: various mathematical formulations were devised, one of the most successful being the Veneziano model (1968).

In reality, therefore, the quark model became accepted because of the weight of experimental evidence that accumulated during the late 1960s, mainly from hadron-hadron scattering experiments carried out using bubble chambers. Brookhaven and CERN were the leading laboratories in the effort, and the discovery of quarks was the collective achievement of a large and dispersed international community of scientists. But there was no single *experimentum crucis*, no individual hero, and no precise moment as which one could say that the existence of quarks had become a certainty.

Of course, this is not to say that the electron-beam experiments at the end of the decade were not of great importance. On the contrary, they probed the structure of the nucleon in a quite different and complementary way, and therefore provided reassurance to physicists that the "quarks" already revealed by hadronic interactions were not some sort of cruel illusion but were likely to be concrete objects in spite of it being impossible to isolate them. The fear that quarks might just be a handy way of thinking had never been far below the surface, and the SLAC data helped to dispel it.

But why did the "SLAC myth" arise? Several different factors may have contributed to it. Institutions such as SLAC generally need to publicise their successes, if only to justify themselves to their funding bodies and to bolster arguments for additional cash in the future. (A quarter of a century later, the cancellation of the Superconducting Super Collider devastated the US particle physics community.) National pride may also have come into it, compounded by a cultural difference which, at least in those days, made Americans more likely than Europeans to promote the significance of their achievements. Rivalry between the West Coast and the East Coast –between SLAC and Brookhaven, and between universities such as Stanford and MIT– may also have been relevant. Furthermore, the award of a Nobel Prize may by itself enhance scientists' and institutions' reputations, ultimately distorting history.

Philosophy may also have played a part. It may not be going too far to suggest that, because of a logical-positivistic philosophy of science, some scientists in the 1960s were inclined to remain sceptical or non-committal about the existence of quarks for many years. Richard Feynman (1969) preferred to refer to "partons" rather than quarks even when he was writing about hadron-hadron collisions. In fact, distinguished West-Coast physicists seem almost to have gone out of their way to avoid mentioning "quarks" –see, for example, papers like that of Bjorken (1969). There were good scientific as well as philosophical reasons for this– the definition of a "quark" was unsettled, the role of gluons was still unclear (although the concept of the gluon had been around for a few years) and a distinction came to be made between "constituent quarks", of which a proton contains three, and "current quarks", of which a proton contains an indeterminate number not less than 3. But whatever the logic, the fact is that a prominent subset of the physics community held back from acknowledging the existence of quarks. So, when the electron-beam data arrived at the end of the 1960s, the appearance of quark-like nucleon substructure could be represented as if it were a new and unexpected revelation.

In conclusion, then: a misleading myth has grown up. Even if quarks were not "constructed" in quite the sense that Andrew Pickering meant, the *story* of the discovery of quarks has been very much a social construction. In fact quarks were not discovered through deep inelastic collisions in California in 1968. Their discovery was a protracted process which began in the middle of that decade, relied predominantly on bubble-chamber observations, and had its centre of gravity in mid-Atlantic.

CROSSING BORDERS
IN MODERN PHYSICS

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 791.

FROM IDENTITY TO INDISTINGUISHABILITY

Enric PÉREZ CANALS
Departament de Física Fonamental, Universitat de Barcelona, SPAIN
enperez@ub.edu

Abstract

It is widely accepted that the papers by Bose in 1924 and by Einstein in 1924-1925 definitely opened the path to the quantum concept of 'indistinguishability'. Since then, distinction in physics between 'identity' and 'indistinguishability' of particles has come to be required.
However, even before the rise of quantum physics, Maxwell, Boltzmann and Gibbs, among others, had to tackle the difficulties and paradoxes that appear when counting identical particles. Later, after Sackur's and Tetrode's first quantum derivation of the canonical partition function of an ideal gas, much confusion arose around its dependence on the number of molecules in the system. Many other physicists, such as Planck, Lorentz or Schrödinger took part in those debates. In 1921, Ehrenfest and Trkal devoted a whole paper to this subject. Clearly, in the days before Bose's seminal work, embroiling and misunderstanding were commonplace.
In considering the emergence of the distinction between 'identical' and 'indistinguishable' particles, we will go through the so-called statistical route to quantum mechanics. The first developments in statistical mechanics became immediately confused and entangled with the irruption of quantum physics. In the first quarter of the twentieth century the mutual influence between both disciplines was profuse.
We will pay special attention to the story of the so-called 'Gibbs Paradox.' We will argue that what is now often known by this name in some textbooks of statistical mechanics did not exist as such in those foundational days.

The statistical route to quantum mechanics in the first quarter of the twentieth century represents a particularly interesting case of interdisciplinary influence. Some of the involved disciplines such as statistical mechanics were practically new, while others, like physical chemistry or thermodynamics, just a bit older. Quantum theory as such was still in a –let's say– embryonic stage

In this communication, I focus on the apparently simplest statistical system: the monatomic ideal gas. In particular, I will focus on the vicissitudes of the concept of identity of its components, the elemental particles, which had its main analytical expression in the dependence of entropy on N, the number of particles.

As for the interdebate, in this particular case, the confussion was so huge, that we can hardly speak of a gradual and reciprocal process of enrichment. At least regarding identity, the wide variety of factors involved in the determination of the N-dependence of the entropy of an ideal gas contributed to the proliferation of arguments and counterarguments, so entangled, that left the question frankly muddled, and far from being clearly understood even after the birth of quantum statistics.

Last month, a more than forty pages article devoted to the Gibbs' Paradox and the statistics of indistinguishable particles appeared in the *Journal of Statistical Physics*.[1] The journal *Entropy* will devote next year a special issue to the Gibbs' Paradox. And these are not isolated cases. For almost one hundred years there has been a continuos flux of contributions, seeking to clarify the question of the identity of the particles with new analysis, new interpretations and new terminology proposals.

Before beginning the story, let me remind some of the results involved in those debates:

- *Nernst Heat Theorem*. Its interpretations, applications, and experimental measures.
- *The quantum hypothesis*. How to quantize non-periodic movements. Extent of the quantum cell.
- *Boltzmann Principle*. Definition of thermodynamic probability.
- How to measure *entropies* in the laboratory.

None of these points were at the time firmly established or with an agreed meaning. In the following I will make a brief review of some of the arguments used when trying to justify the *N* dependence of entropy, in order to establish relations to commonplaces still found in current textbooks and articles. Needless to say, I'm much indebted with previous works on this subject. This communication is based, aside from the original works of the major figures of this story, on the historiographical studies by Desalvo, Darrigol, Monaldi, and Badino, to name only those I have used more often.[2]

Pre-quantum Debate on Identity

Even before the rise of Planck's quanta, physicists had to deal with the statistical treatment of identical particles. Generally speaking, we can say that elementary particles were considered as such in the traditional sense of the word, which could be traced back even to Epicurean atoms. Maxwell wrote, in his *Theory of Heat*, in the ninth edition of 1888, that "The molecules of the same substance are all exactly alike, but different from those of other substances."[3]

Many of the debates that took place on this subject were related to a very famous passage by Gibbs in his "On the equilibrium of heterogeneous substances," in 1876.[4] There, Gibbs pointed out that the expression for the entropy of the mixture of different gases cannot be applied to –let me say– the *mixture* of the same gas.

> ... although the process of mixture [of two different gases], dynamically considered, might be absolutely identical in its minutest details (even with respect to the precise path of each atom) with processes which might take place without any increase of entropy. In such respects, entropy stands strongly constrasted with energy.

Therefore, Gibbs simply stressed the peculiarity of the function that links mechanics and thermodynamics. Maxwell also argued that from a thermodynamic perspective one could not speak of a diffusion within the same gas in the same conditions, that is, within an homogeneous system.[5] Boltzmann saw in the thought experiment by Gibbs just a stroking consequence of the statistical nature of entropy.[6]

This abrupt change of entropy depending on whether the gases in the mixture were the same or different was baptized soon afterwards, as far as I know, by Otto Wiedeburg, in 1894, as 'Gibbs' Paradox.'[7] However, the paradox did not emphasize the statistical nature of entropy, but the fact that with a continuous variation of the microscopic properties came an abrupt change in the macroscopic scale. Anyway, it was stated within a thermodynamic context.

Later, in 1902, in his celebrated book on statistical mechanics, Gibbs did not directly address this issue, but one closely related.[8] When studying mixtures of gases he stated:

> If the particles are regarded as indistinguishable, it seems in accordance with the spirit of the statistical method to regard the phases as identical.[9]

However, in some situations, we can be interested in distinguishing particles. According to Gibbs,

> The question is one to be decided in accordance with the requirements of practical convenience in the discussion of the problems with which we are engaged.

Which is quite within the positivist approach of the whole Gibbs' book. In its last paragraph, we find briefly discussed the case of the *mixture* of the same gas. According to Gibbs, this case clearly shows that when dealing with ideal gases there was no escaping: one had to use what he so-called the generic phase, which involves a permutation factor *N!* Otherwise, the entropy of an ideal gas wouldn't be extensive, which is not acceptable. Boltzmann had himself used a similar argument in as early as 1877.[10] To ensure the extensivity of entropy he took away from the logarithm of the probability of a distribution the term $N\ln N$. Like Gibbs, he noted that the entropy constant, which the introduction of this factor modified, was physically irrelevant. Only entropy differences were actually meaningful.

Hence, before the quantum novelties came, no major drawbacks were attached to the indistinguishability of particles. We can approach the problem by noting that in thermodynamics, the variable *N* has a cardinal sense, that is to say, it only refers to the total number of particles, whereas in mechanics, it may as well have an ordinal meaning so it can also refer to the label of the *N*th particle. Statistical approach has to suppress this divergence in the meaning of the variable *N*. Extensivity is only meaningful with a cardinal *N*.

Nernst Heat Theorem and the Quantization of the Monatomic Gas

The formulation of Heat's Theorem by Nernst in 1906 changed the scenario. One of its most accepted interpretations provided physicists with an absolute reference for entropy at zero temperature. The entropy constant was no longer irrelevant. Some physicists thought that maybe quantum physics could provide an analytical expression for the absolute entropy. That was the idea pursued by those who crossed subdisciplinary borders to show new analysis of monatomic ideal gas. In the following I will mention some of the contributions of those days.

The first attempt took place in 1911 and was made by Otto Sackur, a former collaborator of Nernst now at Breslau.[11] Although far from being an expert on that field, his pioneering work soon attracted others more experienced. He obtained an analytical expression for the entropy constant and related it to what Nernst had christened as the "chemical constant," which in turn appeared in the formula of the vapor pressure. Sackur concluded that the value of the elemental quantum region depended on the number of particles of the system. This result was a consequence of imposing the extensivity of entropy. Planck's initial approach to the subject started with an idea very similar to that of Sackur's.[12]

The next significant contribution was by the young Dutch Hugo Tetrode.[13] It is to him that we owe one of the most popular arguments up to now. I will call it the "interchangeability argument." Clearly inspired by Gibbs' book, Tetrode argued that in a system with perfectly equal and interchangeable molecules, in order to obtain an extensive entropy, the total number of microstates must be divided by *N!* Tetrode tied the property of identity with the requirement of extensivity. A good treatment of the first ensured the fulfilment of the second. We must note, however, that this "interchangeability argument" is only valid for configurations where there isn't more than one particle in an elementary cell. If there's two or more particles in a cell, the number of possible permutations is smaller than *N!*

Tetrode's elementary region, unlike Sackur's, did not depend on *N*. However, Sackur would soon publish new researches rectifying his original result. In 1912, he resorted to the factorial of *N*.[14] But then he rectifyed again. In a new paper, when performing the phase integrals, he divided the volume of the system in small boxes of volume V/N.[15] Then, he calculated the total entropy as the sum of individual entropies. Thus, extensivity was obviously ensured.

Another of the main characters of this story is Otto Stern, in 1913 a collaborator of Einstein's. He worked out a new formula for vapor pressure and, in a different article, linked the chemical equilibrium constants with a kinetic treatment *à la Boltzmann*.[16] In the former, he didn't take into account the difference between oscillators and gases concerning the location of molecules in the solid and its lack in gases. Because of that, his analysis yielded an extensive entropy with apparently no *ad hoc* additions. However, Stern only applied quantization to the solid phase.

Meanwhile, Tetrode tried to improve his arguments after a heavy critique by Lorentz. The renowned Dutch had pointed out a weakness in Tetrode's method: his use of Boltzmann's Principle concerning the definition of the thermodynamic probability.[17] According to Lorentz, "the way in which this application has been made requires further explanation and justification." Tetrode presented a new paper in 1915.[18] According to him, the new "thermodynamic probability" he introduced did satisfy Lorentz, but the justification of the *N!* remained dark. Tetrode admited it was "a difficult question." A physicist who was also working at Leiden, Obe Postma, defended in 1916 the version of Tetrode in front of that of Planck's, inspired in Sackur's first approach.[19] However, Postma thought that the factorial of *N* wasn't related to anything else than "extensivity condition": since the statistical models had to recover thermodynamics it needed no further justification.

A very similar opinion was that showed by Einstein in a manuscript probably read at the *Deutsche Physikalische Gesellschaft* in February 1916, shortly after having read Tetrode's paper.[20] In that communication, Einstein tried to remove "all confusing paraphernalia" around this subject. He expressed his distrust on the classical kinetic models, which he saw not valid enough as to draw too many conclusions from them.

In a very interesting paper by Trkal and Ehrenfest of 1920 they also critized the existing confusion and developed arguments in accordance with Einstein's.[21] They even questioned the reliability of the vapor-pressure formula method. They pointed that:

> It is not an accident that it is always the same point that remains obscure in these theories, viz., how an expression of the form N^{-N} (Sackur) or $(N!)^{-1}$ (Tetrode) can be forced into the "thermodynamic probability *W*" in order to obtain an admissible value for the entropy.[22]

According to them:

> The law of dependence on *N* can only be satisfactorily settled by utilizing a process in which *N* changes reversibily and then comparing the ratios of the probability with the corresponding differences of entropy.

They deal with gas mixtures, where the *N* dependence of a single monatomic gas cannot be calculated. According to Ehrenfest and Trkal, the impossibility of having processes in which one may double the number of particles of the gas, prevents deriving the dependence on *N* kinetically.

The paper by Ehrenfest and Trkal prompted Planck's response, who after criticism had abandoned his original opinion on the subject. In 1916, he had adopted Tetrode's justification of the factorial of *N*.[23] That is, he had adopted the 'interchangeability argument.' In 1921 he persisted in both his justification of the N factor and in the absolute definition of entropy.[24] Certainly, his arguments in terms of symmetry properties of the whole gas model were more specific. In fact, in one of his successive attemps to justify the argument, Planck had also suggested that it may only be valid in the limit. Soon after that, Schrödinger wrote an article in which he examined different understandings of Boltzmann's principle, reaching up to four different definitions of entropy.[25] He also pointed the weaknesses of the 'interchangeability argument.'

Quantum Indistinguishability to the Rescue?

The scenario changed again with Bose and Einstein's contributions.[26] How did Einstein solve the mess, if at all? I can not dwell too much on details which, on the other hand, have already been discussed elsewhere. What I truly want to emphasize is that Einstein radically changed the approach. In terms of Gibbs' ensembles, and loosely speaking, we can say that he made his developments within the grandcanonical ensemble, rather than in the microcanonical or the canonical, where the problem had been posed for thirty years.

Einstein noted that the new expression for entropy had a property that the classical one very much lacked: it fulfiled both Nernst theorem and the extensivity condition. And all that *ad hoc* factors-free. Comparing classical and quantum cases,

he noted that in the former a term N^N had to be removed to obtain an extensive entropy. Although he mentions the 'interchangeability argument,' he doesn't establish any link whatsoever between N dependence and the new statistics.

Despite criticisms, and despite the emergence of the new statistics, the 'interchangeability argument' did not disappear. We find it, for instance, in the book by the American physicist Richard C. Tolman *Statistical Mechanics with Application to Physics and Chemistry*, published in 1927 and signed in August 1926 (over a year and a half after the publication of Einstein's theory).[27] Also in the *Introduction to Chemical Physics* by John C. Slater, from 1939.[28] There we can find an argument repeated in later textbooks: there's no difussion in the same gas because particles are really identical. This "really" was supposed to mean "quantum" identical, not "classical." Schrödinger gave the exactly same solution to Gibbs' Paradox in his *Seminar Lectures* delivered in 1944 in Dublin.[29] However, he did not use the "interchangeability argument," and derived the corrected classical formula for the monatomic ideal gas by performing a mathematical limit, as Planck had already suggested in the twenties. To picture once more time the mess, let me mention that Stern returned to the subject in 1949.[30] He did with a short note on the controversial term in the entropy. Besides ruling out an experimental veredict, Stern claims that "some of the arguments still used can be hardly justified."

Some time in the fifties –I don't know the exact date yet– the confusion got worse, when the term 'Gibbs' Paradox' turned polysemic: a statistical meaning was born. It went on to describe the not-exactly-nice consequences with which one bumbs into when dealing with a non-extensive entropy. This would happen when we use the wrong statistics, that is, classical statistics. Let me note that this new Gibbs' Paradox is not from Gibbs and is not even a paradox. In the stories where this change of meaning can be appreciated, quantum mechanics came to the rescue of classical physics anihilating a paradox that had astonished physicists long before the emergence of quantum mechanics. This attractive reconstruction appears in such valuable books on statistical mechanics as Huang, Reif or Pathria, among others.[31]

I'll finish with a quote of one of these modern textbooks. Kerson Huang's *Statistical Mechanics*, from 1963, reissued in 1987. He justifies the introduction of the factorial of *N* resorting to quantum inherent indistinguishability. There, we find a mixture of classical devices, like the phase-space, and quantum mechanical concepts. However, Huang loops the loop before closing the chapter:

> The foregoing discussion contains the correct reason for, but it is not a derivation of, the "correct Boltzmann counting," because in classical mechanics there is not a consistent way in which we can regard the particles as indistinguishable. In all classical considerations other than the counting of states we must continue to regard the particles in a gas as distinguishable.[32]

Then, although the correct result must be obtained performing a mathematical limit, the correct reason remains that proposed by Tetrode's.

> According to these commonplaces, from classical identity to quantum indistinguishability there's only a factorial of *N*.

UNRAVELING THE NATURE OF COSMIC RAYS. BRUNO ROSSI AND THE SPREAD AND DEVELOPMENTS OF EXPERIMENTAL PRACTICES AND SCIENTIFIC COLLABORATIONS IN COSMIC-RAY PHYSICS BEFORE WORLD WAR II

Luisa BONOLIS
AIF – History of Physics Group, Rome, ITALY
luisa.bonolis@roma1.inf.it; http://www.luisabonolis.it

Abstract

During the late 1920s/beginning of the 1930s, particularly in connection with the birth of Enrico Fermi's and Bruno Rossi's research groups in Rome and Florence, strong relationships were established between Italy and other European countries such as Germany, Great Britain and France, as well as with some physicists of the US scientific community. Bruno Rossi, an outstanding scientist in the study of cosmic rays and the pioneer of this research field in Italy since the early 1930s, is a prominent example in this sense. His friendship with Fermi, Bothe, Blackett, Heisenberg, Bethe, was instrumental for the exchange of knowledge about experimental practices and for theoretical discussions. Rossi was also successful in attracting the interest of physicists such as Arthur H. Compton and Louis Leprince-Ringuet on the problem of cosmic rays. The ties established during the 1930s and the solidarity of many members of the international scientific community gave Rossi the courage to begin a new life in a new world when he was obliged to leave Italy after the enactment of fascist racist laws in 1938 and were instrumental for his later contribution to the rebirth and development of European physics after the war.

Cosmic-Ray research becomes a branch of physics

Between the end of the 1920s and the beginning of the 1930s, as Enrico Fermi (1901-1954) was building up a research group in Rome which was preparing to explore the nucleus, Bruno Rossi in Arcetri, near Florence, was eager to begin work on some experimental project addressing itself "to the fundamental problems of contemporary physics."[1] Then, in 1929, a paper by Walther Bothe and Werner Kolhörster on the nature of the extraterrestrial penetrating radiation appeared,[2] which was "like a flash of light revealing the existence of an unsuspected world, full of mysteries, which no one had yet begun to explore."[3]

At that time, the problem of the nature of cosmic rays did not actually attract general attention, probably because of the widespread belief that the astonishingly penetrating cosmic rays could not be anything else but gamma-rays of very high energy. Bothe and Kolhörster had used the brand new Geiger-Müller counter, which had an improved sensitivity and performance, if compared with other kind of counters and with ionization chambers. Their innovation was to place two Geiger-Müller counters one above the other, with a 4.1-centimeter layer of gold between them and then record the coincidences between the two counters. From this arrangement they argued that coincidences could be produced only by individual ionizing particles crossing both counters, which they thought to be high energy electrons.

Bothe and Kolhörster's experiment, in providing evidence of the enormous potential of the coincidence method, represented the very first attempt to determine the nature of cosmic rays, and contributed to focus the physicists' interest on the radiation found at the place where measurements were made. Both the novelty of the research topic and the low cost of the research tools were the key ingredients of Bruno Rossi's excitement. In just a few months he built his own Geiger-Müller counters, devised a new method for recording coincidences,[4] and began some experiments. The Geiger-Müller technique which Rossi introduced in Italian physics would play a crucial role in the well-known discoveries made by Enrico Fermi and his group in Rome in 1934.[5]

Internationalism and co-operation

In the meantime Rossi had written to Bothe, telling him that he would have liked to spend some months in his laboratory. Bothe's answer was a positive one, so Bruno Rossi left Arcetri in the late 1930 spring thanks to a grant of the Italian National Council of Research. At the time Germany was nearly a paradise for Italian physicists. Fermi himself had been in Göttingen and Leyden after getting his laurea in 1922. Berlin was then the heart of modern physics, and the 24-year-old Rossi had the occasion of meeting Albert Einstein, Max Planck, Otto Hahn, Lise Meitner, Max von Laue, Walther Nernst, Hans Geiger, and other prominent physicists of the time. In particular, he became acquainted with Werner Heisenberg, and with Patrick Blackett, the latter visiting from England; with both he established a friendly relationship. Blackett was a recognized expert on cloud chambers, so that Rossi asked him about the possibility of sending his collaborator Gilberto Bernardini to Cambridge in order to learn this important technique. Blackett's wife was Italian, one more reason to form close friendship with his Italian colleagues.

Rossi's experiments in Berlin provided a more direct and sharp proof of Bothe and Kolhörster's conclusion, but went further in finding the first hints of the phenomenon of a secondary radiation generated by cosmic rays in lead shields. It is to be remarked that Bothe must have been very confident in the young Italian physicist, so much as to reveal him his own secrets for preparing reliable Geiger-Müller counters.

When Rossi was in Berlin, Bothe and Kolhörster went for an expedition to the North Sea and the northern Atlantic Ocean to study the dependence of cosmic rays intensity on the geomagnetic latitude, even if with a negative result. The existence of this geomagnetic effect, connected with the charged nature of cosmic ray particles, had in fact not been definitely confirmed yet. Bothe made him aware of the extensive work that the Norwegian geophysicist Carl Störmer and his pupils had carried on for years on the very complicated mathematical problem of the motion of charged particles in the field of a magnetic dipole, a good approximation to the Earth's magnetic field. Störmer was interested in the trajectories of particles approaching the Earth in the direction of the Sun, but Rossi found out that the answer he was searching for was contained in a formula derived by Störmer. On July 3, during his stay in Berlin, Rossi sent a short note to the *Physical Review* where he arrived at the following conclusion: besides the already expected latitude effect, a second phenomenon

must exist, the East-West effect, which would be revealed by an asymmetry of the cosmic-ray intensity with respect to the plane of the geomagnetic meridian, with more particles coming from East or West, depending on whether the particle charge was negative or positive.[6]

Rossi must have discussed this topic with Werner Heisenberg, during one of the latter's frequent trips from Leipzig to Berlin, because, on August 19, 1930, Heisenberg wrote him a letter asking to summarize Rossi's calculations on the motion of a high-energy electron in the Earth's magnetic field. Rossi answered only on September 13, during the last days of his German sojourn. After a series of detailed passages, Rossi arrived to the same formula contained in his article on the *Physical Review*. A trace of the Rossi-Heisenberg dialogue on cosmic rays is contained in a series of letters now preserved in the Archives of Padua University (not accessible at the moment) which have been published in 1993.[7] As a theoretical physicists at the frontiers of quantum mechanics, and involved in the nascent quantum electrodynamics, Heisenberg had immediately become aware of the interesting new perspectives opened by the latest experiments on the nature of cosmic rays.

As soon as Rossi was back in Arcetri, he began to work searching the proof of the existence of the East-West effect, which could provide a completely different proof of the corpuscular nature of the cosmic radiation as well as an indication on the sign of the charge. However, within the errors, the experience gave a negative result. Being aware that the asymmetry would become pronounced only at low geomagnetic latitudes and at sufficiently high elevation to afford the observation of cosmic rays of comparatively small energy, Rossi planned an expedition to Asmara, the capital of the Italian colony in Eritrea, a town rising at an altitude of 2370 m, and at a geomagnetic latitude of 11° 30' N.

On November 19 Rossi wrote to Heisenberg in reply to the latter's letter of October 6. Rossi apologized for the great delay, and said that only in the previous days had he been able to look at Heisenberg's notes "on the nature of the Ultrastrahlung". He compared his results on the "forbidden regions" with Heisenberg's ones observing that their results were nearly coinciding, even if they had been obtained by different methods. Rossi announced, too, that he was going to publish a preliminary article on the work carried out in Germany.[8]

By the summer of 1931 Rossi had performed a series of experiments (deviation with an electromagnet and study of intensity of cosmic rays with a counter-telescope at different inclinations to the vertical line) aiming with different means at studying the nature and behavior of the cosmic rays.[9]

In the meantime, from May 20 to May 22, 1931, the first international −but European in character− conference on nuclear physics was held at the Eidgenössische Technische Hochschule in Zürich. Rossi had the occasion to meet Marie Curie, Frédéric Joliot, George Gamow (who delivered the opening lecture), Patrick Blackett, Lise Meitner, Bothe, Rudolf Peierls ,Wolfgang Pauli, Maurice De Broglie and Louis Leprince-Ringuet. At the time they were working in Paris on the artificial disintegration of elements, and like James Chadwick were performing their researches using the valve counter invented by Heinrich Greinacher, as a mean of detecting the passage of protons generated during the disintegration process. From the acquaintance with Leprince-Ringuet, and the interest in the new technique of the valve counter the idea of a visit to Paris aroused, which took place during the following year 1932, thanks to a Volta grant provided by the Accademia d'Italia. It was an important occasion for the exchange of knowledge about counters, and especially in arousing Leprince-Ringuet's interest in cosmic rays: "Le séjour de Rossi fut des plus fructueux: par un echange bien naturel, le laboratoire du duc de Broglie fut initié aux compteurs d'eléctrons et aux coïncidences qui permettent de reconnaıtre les rayons très pénétrants au milieu d'autres, plus mous, et definir leur direction. C'était la porte ouverte vers le monde merveilleux des rayons cosmiques [...]".[10] Rossi did not use the whole grant: he anticipated his return to Italy in order to participate to a competition for a chair of experimental physics. This proved a most lucky circumstance: when he was forced to emigrate in 1938, after the enactment of fascist laws against Italian jews, he requested to complete his stay abroad and was thus able to get some money and the visa on his passport in a short time. After the war, when Rossi was at the Massachusetts Institute of Technology, a tight collaboration was established with Leprince-Ringuet's group at the École Politechnique.

That same 1931, an international conference on nuclear physics was organized in Rome by Enrico Fermi with the support of Orso Mario Corbino. The meeting, to which prominent American physicists such as Robert Millikan and Arthur Compton participated, was held from October 11 to 17. The presence of the leading brains engaged at the frontiers of physics research in the field of nuclear physics and cosmic rays gave the event enormous importance, and put the seal on the new disciplinary identity, helping the young Italian physicists to familiarize with current problems. A well known

photograph taken during the Conference shows the group of physicists gathering on the stairs in front of the Physics Institute of Via Panisperna. Among the others Marie Curie, Louis Brillouin and Jean Perrin from France; Arnold Sommerfeld Paul Ehrenfest Werner Heisenberg, Walther Bothe, Hans Geiger, Otto Stern, Peter Debye from Germany and Holland; Francis W. Aston, Patrick Blackett, C. D. Ellis, R. H. Fowler and Nevill Mott from Great Britain; Niels Bohr from Copenhagen; Wolfgang Pauli from Zürich; Arthur Compton, Samuel Goudsmit and Robert Millikan from the US. Ernest Rutherford was the great absent, so that a telegram was sent by the group. The fourth day of the conference was dedicated to the problem of cosmic rays and Fermi invited Rossi to give an introductory speech. He made a detailed and cogent discussion, also explaining the reasons why he thought that Millikan's assumption, according to which cosmic rays were "ultra-gamma radiation" resulting from the synthesis of elements in the Universe, could not be correct. Millikan did not like Rossi's discourse; he considered him only an arrogant young man and for a number of years thereafter chose to ignore his work altogether.

On November 11, immediately after the conference, Heisenberg wrote again to Rossi: "I still remember the Roman days with joy, the congress was really one of the best and instructive I ever participated until now." Heisenberg, who had much reflected on these topics during the previous months and after the meeting, asked for Rossi's opinion: "I have lately made some calculations on cosmic radiation and I collected the formulas in a small manuscript. I would be very grateful if you could be so kind as to read it and write me how much its content is trivial, well known, and how much wrong, and then send it back. You probably will laugh at the theoretician's list of wishes [...]". On December 8 Heisenberg asked Rossi to send back his manuscript because he needed it for a discussion, and after 4 days he wrote again thanking him and mentioning something about the final draft of Rossi's article on the absorption experiment in 1 meter lead: "I am really burning with interest in the manuscript you announced."[11] A series of letters exchanged with Heisenberg between December 8, 1931, and March 21, 1932, are discussing Rossi's experiments on the absorption in 1 meter lead, and especially on the secondary radiation generated in the metal screens above the counters. According to what Rossi told later, a paper reporting on this effect was rejected by *Die Naturwissenschaft*, and was accepted by the *Physikalische Zeitschrift* only after Heisenberg had vouched for its credibility.[12] On February 10 Heisenberg thanked Rossi for his "new work" which he had "studied with great interest". Heisenberg also told how curious he was about the "angular distribution of secondary particles". That same spring Heisenberg published a long article discussing cosmic rays where Rossi's experiments were widely quoted.[13]

In the meantime Hans Bethe, who spent some time in Rome with a Rockefeller scholarship, wrote enthusiastically about Fermi to Arnold Sommerfeld. He was going to spend the rest of his Rockefeller fellowship in Cambridge, and was very sorry for having to leave Italy: "The stimulus I have here by Fermi, is larger by orders of magnitude [...] Dirac is well known for speaking only one word per light year, and the other people in Cambridge are far from having the general view of the quantum theory that Fermi has."[14] At that time Bethe had just published a landmark paper on the interaction of radiation with matter.[15] He disagreed with Millikan's views on cosmic rays, but at the same time he regarded Rossi's researches with great favor, and during his stay in Italy he visited Rossi in Florence. They were nearly the same age, and it was easy to establish a human relationship, which later proved crucial in Rossi's life. Actually, in being closely bound to the nascent quantum electrodynamics, the archetype of quantum field theories, Rossi's work was followed by theoreticians such as Heisenberg, Fermi, Bethe, Heitler and Bhabha. The latter, too, spent some time in Rome with Fermi during the 1930s, and well knew Rossi's work which widely quoted in his articles. Later, Bhabha and Heitler used Rossi's data to establish a satisfactory quantitative agreement with their theory of the electromagnetic cascade.

From co-operation to collaboration

Rossi's talk on cosmic rays during the Roman conference had stimulated Arthur Compton and provided the initial motivation for the latter's new research program in cosmic rays. Going back to the US Compton thoroughly studied Rossi's talk at the Rome Congress, as well as other recently published cosmic ray works, and decided to change his main research interest. He organized a worldwide cooperative project involving tens of physicists (with all investigators using identical large ionization chambers) eventually demonstrating that the intensity of cosmic rays is correlated to the magnetic rather than geographic latitude. This was one of the first examples involving so many physicists all over the world working at the same research project.

[15] H. Bethe, "Zur Theorie des Durchgangs schneller Korpuskularstrahlen durch Materie," *Ann. Phys*. 5 (1930) 325-400.

In September 1933 Rossi and his collaborator Sergio De Benedetti went to Eritrea to carry out the planned experimental tests on the existence of the East-West effect. During the journey from Spalato to Massaua, which took about a week, they measured the dependence of cosmic-rays intensity using a ionization chamber provided by Compton thus participating to his great enterprise.

When Rossi and De Benedetti arrived in Eritrea and observed the existence of a difference in the intensity of cosmic rays between East and West, experiments proving this effect had already been announced in two letters sent to the *Physical Review* by Luis Alvarez and Compton, as well as by Thomas Johnson. The study of the asymmetry predicted by Rossi since the summer of 1930 was now confirming the corpuscular hypothesis of the nature of the primary radiation and revealed that the primaries were largely positively charged.

Compton's interest in cosmic ray research was the beginning of a reciprocal liking between the young Italian physicist and the more mature American Nobel Prize winner which would prove important after a few years, when things turned difficult and Rossi was forced to leave Italy in 1938.

In 1931, Rossi had met again Blackett in Zurich and in Rome, and they certainly reinforced the idea of a collaboration. Blackett's interest in nuclear physics and cosmic rays was triggered by the arrival in Cambridge of Rossi's young and brilliant collaborator Giuseppe Occhialini in the spring of 1931. Occhialini brought in Cambridge Rossi's ideas on cosmic rays and especially the technique of coincidence counting with the Rossi electronic circuit. The cross-fertilization between Rossi's methods and Blackett's extraordinary competence in cloud-chamber techniques represented the beginning of a new era in the physics of detectors. At the moment it provided a clear evidence for the existence of the secondary "showers" observed by Rossi and the proof of the existence of the electron-positron production implied by Dirac's relativistic theory of the electron. After the war, in 1947, Occhialini collaborated with Powell's group to the discovery of the pion. These two scientific adventures have by and large been explored by historians. Here it will suffice to remark that the strong tradition of collaboration established between Italy and Great Britain became very important after World War II, when European physicists became aware that, in order to tackle the new tasks of reconstruction and of competition with the mighty community of American physicists, they had to organize in international groups. Occhialini's sojourn in England is a typical example of a strategy implemented by Italian physicists to learn new experimental practices and theoretical tools outside the restricted national reality, as well as to experience a richer scientific context. During the 1930s Germany (Berlin, Hamburg, Leipzig, Göttingen, Heidelberg, Frankfurt), Great Britain (Cambridge, London), France (Paris), Denmark (Copenhagen), Sweden (Stockholm, Uppsala), Switzerland (Zurich) attracted Italian physicists slightly younger than Fermi.[16]

When Rossi and his wife Nora were obliged to leave Italy on October 12 1938, Rossi was offered a position in Manchester by Blackett, who had just succeeded W.L. Bragg as the Langworthy Professor of Physics. After a short stay in Copenhagen with Niels Bohr ("The human interests, the lively intellectual climate, the sane vision of political events that were the essence of the 'Spirit of Copenhagen' went a long way toward clearing our minds, and strengthening our confidence in the future"),[17] Rossi and Nora moved to Great Britain in the following December. In Manchester, where he remained until the early summer of 1939, Rossi found A. C. B. Lovell, G. D. Rochester, J. C. Wilson, and Lajos Jánossy, a refugee from Hungary. Rossi's arrival in Manchester was instrumental in triggering a brand-new program on cosmic ray researches. During that period, Rossi's tie with Blackett transformed in a lifelong friendship and a collaboration in particle physics.

In June 1939 Rossi and his wife Nora left for the United States. Rossi had been invited by Compton to participate to an international congress on cosmic rays to be held in Chicago. After the meeting, thanks to Compton, Rossi received an offer of a research associate post from the University of Chicago paid by the Committee in Aid of Displaced Foreign Scholars. By accepting this position he made a final decision to remain in the United States and became one of the about one-hundred physicists who immigrated to the United States between 1933 and 1941 fleeing Nazi Germany and Fascist Italy. Later Hans Bethe had a clue role in recommending that he be appointed to fill a vacant associate professorship at Cornell University in Ithaca, New York, where he remained until the spring of 1943, when he moved to Los Alamos and was involved in the Manhattan project.

After the war Rossi accepted a position at MIT, but constantly supported Italian physicists inviting them to work at the Laboratory for Nuclear Science. His group at MIT flourished, becoming internationally renowned and attracting researchers from all over the world. By that time a marked shift had occurred in the center of gravity of physics research towards the United States, where big science was already a reality. Collaboration became a vital necessity for European physicists. Relationships established before the war were at the root of the rapid reorganization and flourishing of post-war physics in Europe. Typical in this sense were cosmic ray researches with balloons during the period 1952-1955. They prepared physicists to work on large-scale international projects, setting the stage to the world-scale networks which would soon characterize research at the newly founded European laboratory for nuclear research (CERN) in Geneva.

[16] I owe to Matteo Leone a clear scheme of the centers visited by Italian physicists during the 1930s.

"IF A LOT OF RADIUM WOULD BE SUFFICIENT TO MAKE IMPORTANT DISCOVERIES". VIENNA AS A NODE IN THE NETWORK OF EUROPEAN ATOMIC RESEARCH CENTRES

Silke FENGLER
Institut fuer Zeitgeschichte, Universität Wien, AUSTRIA
silke.fengler@univie.ac.at

Abstract

The paper depicts Vienna as a node in the network of European atomic research centres in the interwar years. On the one hand, it sheds light on the strategy employed by Austrian physicists to maintain a position in the network of European research laboratories, which had been dominated since the early 20th century by the French and British schools. Most notably the lending of radioactive substances to radioactivists at home and abroad will be considered. On the other hand, the paper focuses on the scholars visiting Vienna in the 1920s and early 1930s: Which countries did they come from? What impact did their stay have on the local situation, as well as on their further career abroad? Among the factors influencing scholarly mobility, the role of the International Education Board in promoting Vienna as a research centre of atomic physics is studied in-depth.

The situation before World War I

The first institute entirely devoted to the research of radioactive phenomena was founded in Vienna and not in Paris, as one might have expected. On the occasion of its opening in 1910, the Institute for Radium Research received three grams of radium. It had been produced by order of the Austrian Academy of Sciences which thus initiated the formation of an Austrian radium industry. This industry was based on the exclusive exploitation of uranium-rich Bohemian silver mines in St. Joachimsthal. With the Austro-Hungarian government monopolizing the radium market from 1908 on, radium prices skyrocketed due to an ever increasing medical demand.[1] As the Institute maintained good relations with the local radium industry, Vienna had a competitive edge against other laboratories. Before the beginning of the war, it became an important node in the international network of radioactivity research. This network was based on the exchange of radioactive preparations and apparatus, as well as on the circulation of researchers among the centres in Paris, Berlin, Manchester, and

[1] M. Rentetzi, The U.S. Radium Industry. Industrial In-House Research and the Commercialization of Science, *Minerva*, 46 (2008), 438.

Vienna.[2] Between 1913 and 1922, 19 foreign scientists worked as guest researchers at the Radium Institute. The majority came from the German-speaking countries, some from Scandinavia. Occasionally the Institute welcomed visitors from Belgium, Britain, and from overseas.[3] A considerable part of the visitors hailed from those Habsburg crown lands where conditions for radioactivity research were less favourable than in Vienna.[4]

The situation after the war

The war left the scientific field of radioactivity in a state of devastation equal to that of the military battlefield. Belonging to the war enemies of the Entente powers, Austrian scientists along with their German colleagues were banned from international scientific organisations. Nevertheless, they lost less credit among their peers than the Germans. Despite economic, social and political hardships in the wake of the war, Austrian radioactivists soon tied in with old networks. Their countless appeals to re-enact the 'apolitical' international scientific community of the pre-war period were successful mainly in Britain and the United States.[5] Marie Curie, on the contrary, did not actively seek to revive contacts with Austria until 1923.[6] From the financial viewpoint, the Physics Institutes in Vienna faced dire straits. However, when IEB representatives visited the Radium Institute in the mid-1920s, they assessed the value of radioactive stocks at 200,000 US-dollars, and they had good reason to believe that Vienna disposed of more than enough material to continue scientific work.[7] The Institute had in fact no rivals in terms of access to radioactive materials, except for the Laboratoire Curie in Paris.

Notwithstanding that the Radium Institute's regulations prohibited the hiring out or selling of radioactive parent substances to third parties, Ernest Rutherford bought the radium he had borrowed from the Austrian Academy back in 1908. The money, paid in several instalments, helped the Institute get over its financial difficulties during the 1920s. The Cavendish Laboratory in Cambridge in turn disposed of a comparably large amount of radium which enabled Rutherford to open the new research field of atomic disintegration. The ban was lifted a second time when in 1925 Marie Curie received a gram of ionium-thorium oxide as a loan from the Viennese.[8] Following the rules of a reputation-based exchange economy, Curie was prefered to other less renowned colleagues.[9] As we shall see, the Institute expected advice how to make strong polonium sources in return for the service. There was no such ban on selling or lending out radioactive decay products such as radium 'emanation', rare earths preparations,[10] and radioactive rock samples.[11] The major part of preparations went to the German-speaking radioactive community, Scandinavia, and the Netherlands. These countries became the focal point for Austrian radioactivists who wanted to escape the poor conditions in their home country immediately after the war.[12]

The role of the International Education Board

Apart from the abundant stock of radioactive materials inherited from pre-war times, there were also institutional factors that helped Vienna regain its status in the 'radioactive' network. The International Education Board (IEB) played a pivotal role in promoting the city as a centre for atomic research during the 1920s. According to John D. Rockefeller's will, the money entrusted to the IEB should be spent on the promotion of the educational system all over the world. Wickliffe Rose, director of the IEB from 1923 to 1928, ultimately aimed at fostering the industrial and agricultural education in the newly founded states of Central and Eastern Europe. As larger aims of social reform turned out to be unattainable, Rose

rested his hopes on the training of a small and highly educated elite.[13] The national elites should be trained in regional centres supported by IEB. While the IEB spent large sums on founding new laboratories in the United States, contributions were made primarily toward already existing European laboratories. Unlike Cambridge, Paris, or Berlin, Vienna never featured on the IEB's lists of the world's outstanding physical laboratories.[14]

Augustus Trowbridge, at the time head of the IEB's science department, advanced the idea of promoting international migration of promising young scholars with the aid of scholarships and grants-in-aid, supplementing the efforts of national governments. In line with Rose's strategy to promote Central and Eastern European countries, Trowbridge assigned a special task to the Radium Institute in Vienna. In the spring of 1925 he explained to his fellow trustees: *"It is A*[ugustus]*.T*[rowbridge]*.'s own impression that it* [the Radium Institute] *is a case of a good institution, fairly well equipped with a splendid position to serve the entire South-East of Europe, as a center at which good research work in an important branch of modern physics is being done, but being done under what to us westerns would seem almost impossible working conditions for the lack of almost everything we are accustomed to have in such an institute.* […]*; most of the students are from the lower Danube regions, where conditions are still worse, where even the foreign journals are not available, as they are here, thanks to the Institute's being able to effect exchange through its publication.* […] *there is no lack of advanced students who seem somehow to be able to live in Vienna and carry on work; It seems* [...] *that for the next year or two, it would be better not to grant fellowships to Hungarians, Czechs, Poles or Bulgarians for the study of physics in Western Europe, but rather let them seek what is still the natural center, Vienna, where they can partially support themselves while they carry on their work.* […] *The Radium Institute of Vienna ought to be a natural feeder from South-eastern Europe to the laboratories of Madame Curie and Sir Ernest Rutherford.* […] *the Institute is serving a very valuable purpose in keeping alive a spirit of the value of research in a pure science in a country which is the natural cultural center of a vast region."*[15]

Contrary to what Trowbridge and his fellow trustees had expected, the majority of foreign radioactivists visiting Vienna during the early 1920s did not hail from Central and Eastern European countries. By contrast, there was a considerable inflow of visitors from Western and Northern Europe to the Institute. Vienna became a *"new Mecca"*[16] for young Scandinavian, Dutch, and German radioactivists, to no small part because of the country's decayed economic circumstances. Runaway inflation made a stay in Austria affordable for researchers from countries with relatively stable monetary systems. Besides, formerly neutral countries such as Sweden or Denmark hardly made any political reservations against Austria.[17] In scientifically backward countries such as Hungary, Poland, Spain, or Czechoslovakia, fellowships were provided to enable the junior scientific staff to get a training in important research centres abroad.[18] Among scientists from the successor states of the Habsburg monarchy, however, cultural and political alienation contributed to the dwindling attraction of the Radium Institute. Many a man tried instead to reactivate contacts dating from pre-war times to Britain, France, and Germany. František Běhounek, for example, co-founder of the state-run radiological institute in Prague, made contact with Marie Curie in Paris. Stanisław Loria, Marian von Smoluchowski's successor on the chair of physics at the University of Lviv, addressed his former supervisor, Rutherford in Cambridge.[19]

There is some evidence that the Laboratoire Curie in Paris attracted a larger part of scholars from Central Europe. Marie Curie not only strongly promoted the training of young scientists from these countries.[20] She also maintained close affiliations with a number of home and foreign philanthropic foundations. There was thus sufficient prospect that the Czech, Polish, or Hungarian scholars would be awarded a grant at her laboratory.[21] What was more, the Radium Institute clang to its long-established policy to first and foremost welcome post-doc and senior scholars from abroad. Its director Stefan Meyer unwarily made the case for his Institute, pointing to the great number of scholars who had worked in Vienna and who had come to take up a professorship in the meantime. Most of the former visitors held professorships either in Austria, or in the successor states of the Habsburg monarchy.[22] The IEB's initial strategy to promote the Institute as a training centre for Central and South Eastern European scientists worked out only partially, however. On the occasion of a trip to Vienna in the

mid-1920s, Trowbridge noticed *"a great number of young scientists from all through the Balkans* […]*, working at the various institutes connected with the University"*[23] It is peculiar to the IEB's failed strategy that not a single beneficiary of its fellowship or grant-in-aid-programme working in Vienna hailed from Central or South Eastern Europe. The majority of scientists, among them a remarkably high amount of women, either worked without being paid, or received smaller grants from the German Notgemeinschaft, or other private donors.

Among the foreigners who came to Vienna in the early 1920s was Hans Pettersson. Even though many Swedish laboratories were comparatively well equipped, Pettersson found the necessary radioactive sources he needed for his work at the Radium Institute.[24] The Swedish physicist set up a small group of scientists to investigate the process of artificial disintegration of atomic nuclei. The Viennese group grew in size to almost 30 persons in the 1930s, including chiefly scientists from Austria, but also from Bulgaria, Hungary, Germany, Sweden, and the United States. Placing high hopes on Pettersson's stimulating effect, the IEB provided a sum totalling 69,725 US-Dollars by 1935 for atomic disintegration research in Vienna.[25] This sum was far below the money given to the Cavendish, or most of the American universities. However, Curie's laboratory in Paris, or the lab of Heike Kamerlingh-Onnes in Leiden received less money than the Viennese. The German Notgemeinschaft, too, granted rather generous aids for the purchase of apparatus, and it provided fellowships. Apart from German and US-funding, Pettersson succeeded in raising funds from Swedish philanthropic societies and patrons.

The Viennese atomic research group was highly productive: During the first six years they published 50 papers, one monograph on artificial disintegration, and several comprehensive reports. Their experiments gave rise to a lengthy and heated scientific controversy with the Cavendish over the fissionability of light elements.[26] As the group became more and more visible within the scientific community, the IEB's objective in supporting the Radium Institute gradually changed. In 1926, its officers came to the conclusion that *"in radio-active work* [there is] *a real need of obtaining more data on which to develop further theoretical considerations. If there is only one center, provisional hypothesis is likely to result in the field not being thoroughly covered, whereas the existence of two centers, not in complete harmony as to facts nor theory, leads to a more careful criticism of the work of each group and is extremely important for the development of subjects"*.[27] Pettersson and his co-workers came off as the losers of the controversy, and a rather negative image of the group's alleged policy of spreading erroneous results persisted among their international peers. Nevertheless, the IEB decided to continue supporting atomic research in Vienna. The funding was in line with the Board's general policy to encourage competition among various laboratories, in order to advance and to counterbalance the overpowering Cambridge school: *"In* [Cambridge] *Physics there seems to be a slightly unhealthy feeling of superiority, which is due, of course, to the fact that for the past twenty-five years the English have certainly led in that field. They are perhaps a trifle too 'smug' and they are certainly a bit too 'inbred'."*[28]

While the outcome of the controversy did not provoke the Americans to stop their funding, it certainly made it harder for Viennese scholars to pursue a career in science abroad. Pettersson was not the only one who had a hard time continuing his career in Sweden after his return in 1930. As the Austrian physicist O.R. Frisch –who had set off for research work in Berlin earlier– recalled: *"My supervisor, Karl Przibram, told me with sadness in his voice, 'You will tell the people in Berlin, won't you, that we are not quite as bad as they think?' I failed to persuade them."*[29] Apart from Pettersson, none of the physicists involved in atomic research in Vienna during the interwar period gained enough reputation to be considered for a professorship abroad.

New industrial ties and the Viennese polonium network

The fact that the United States became the world's largest provider of radium had put Austria's powerful position into question well before the end of the war. Moreover, with the demise of the Habsburg Empire, Austria no longer ruled over the Bohemian mines. Carl Ulrich, the director of the Imperial radium factory in Joachimsthal, was fired in 1918. Working as an unpaid researcher at the Radium Institute, he became crucial in re-building ties with the radium industry. The Union Minière du Haut Katanga, a Belgian mining company, had begun to exploit uranium ores in the Katanga region in 1921. Well aware of the Institute's excellent relations with the Austrian radium industry, the company hoped to get advice on the industrial

production of radium. Indeed, with the aid of Viennese researchers the company began to produce radium in 1922, and it soon drove the American producers out of the market, securing a monopoly for almost ten years. Even though the Union Minière entertained much closer industrial relations with the Curie family later on, it sold rather large amounts of radioactive material to the Radium Institute at production costs or even provided it for free in exchange for expert advice.

Belgian shipments to Vienna included basic raw material for the production of polonium. Already in 1918 the Radium Institute had started to produce polonium from Austrian radioactive material at small scale and at irregular intervals.[30] The capacity of the early polonium preparations was however limited.[31] Given their short half-life, a continuous production was necessary. With the methods known at the time, this was a tedious task. Besides, a lot of residue input was necessary. Polonium sources took on greater significance in the mid-1920s, after the Viennese physicist Ewald Schmidt had discovered their suitability as α-ray emitters for experiments on atomic disintegration. In order to save their own resources, the Viennese obtained a strong preparation from the Curies in exchange for a gram of ionium-thorium oxide. Contrary to the Viennese, the Curies decided against partitioning their polonium stocks on several small plates. Their ultimate aim was to concentrate the material available in one strong preparation.[32] Inviting the Hungarian radiochemist Elisabeth Rona to Paris, they acquainted her with the French method of concentrating and purifying polonium from radium D solutions.[33] Back in Vienna, Rona refined Curie's method, and before long the Viennese outperformed Paris in producing the strongest polonium preparations. [34]

The new sources allowed for crucial atomic disintegration experiments at the Radium Institute.[35] With a number of European laboratories entering the field of atomic research in the aftermath of the Vienna-Cambridge controversy, the demand for strong polonium sources grew. Whereas James Chadwick of Cambridge used a strong polonium preparation made from radon capsules he had obtained from a hospital in Baltimore,[36] many other atomic physicists had insufficient access to polonium. Unsurprisingly, requests for a share of the Viennese stock became more frequent in the late 1920s.[37]

The Radium Institute distributed its supplies rather strategically. In order to give the Viennese group a leg-up, only the weaker preparations were sent to colleagues abroad.[38] Those scientists who were ready to contribute to solving the controversy were most likely to get a polonium preparation. One of the first was the Institute of Theoretical Physics in Halle, Germany. By means of a Viennese polonium source, Heinz Pose showed the existence of discrete energy levels in the nucleus, while studying the nuclear reactions of aluminium nuclei bombarded with α-particles. He was the first to describe the effect of resonance transformation in a nuclear process.[39] The strong Viennese polonium sources thus became the basis of a new exchange network, opening doors for cooperation between the Austrians and their colleagues abroad.[40]

From feast to famine – Nuclear research in Austria during the 1930s

The discovery of artificially induced radioactivity in 1934 signalled the end of a period in which research was constrained by the scarcity of radioactive ores. As natural radioactivity gradually disappeared from view as a source for and object of research, radium tended to lose its capital value within the scientific community, which decreased at the same time its strategic value for the Austrians. With the gradual introduction of large scale apparatus into nuclear physics, scientists became more and more dependent on state funding and private philanthropy in order to gain access to the new tools. Meanwhile, the Rockefeller Foundation had changed its policy, focusing financial support on the life sciences and selected areas of geography. In Vienna, neither the technical equipment available, nor the scientific specialisation of the nuclear research group members permitted a reorientation towards the new funding policy in the short term.[41] The German

Forschungsgemeinschaft likewise cut back its funding of Austrian science after 1933, mainly for political reasons. With Pettersson's return to Sweden, Swedish philanthropists also stopped their funding. The Austrian ministry of education took the withdrawal of funding from abroad as an excuse to suspend further support for nuclear research. Compared to other centres of nuclear research at the time, the Viennese group lacked an influential spokesman to speak out against the drastic measures. The lack of funding, as well as the withdrawal of key personnel created a grave crisis for Austrian atomic research from the mid-1930s on. The Viennese high hopes of catching up with international developments within the German nuclear research programme after 1938 were soon dashed. In the course of the war, Austrian nuclear science became once and for all marginalized.

Abstract

The advent of the Republic in 1910 brought with it important reforms to higher education in Portugal. In spite of severe political and financial difficulties of the next two decades, Portuguese universities financed the graduation studies of few young teachers abroad. Despite these relevant initiatives the Portuguese republican government was not successful in creating a national institution capable of promoting and funding the organization of scientific research in the country. Only in 1929 did the government set up this kind of institution, the Junta de Educação Nacional *(JEN) [«National Board of Education»], with the aim of funding research centres in the universities and of providing grants for students to continue their advanced studies both at home and abroad. In the thirties, an important group of young scientists continued their studies in renowned European universities and laboratories where some of them attained their PhD degree. Paris University was the most sought after university for post-graduation in Chemistry, Mathematics and Physics and the Curie laboratory received an important group of Portuguese students during this period. After four years abroad and having established important international scientific links, some of these young scientists returned home and played an important role in their universities promoting the* rebirth of a scientific movement. *This lasted until the end of the Second World War, when several of them were dismissed from their positions because of their active opposition to Salazar's dictatorship.*

[1] This work is financed by funds FEDER through the Operational Competitiveness Factors Program (COMPETE) and national funds through FCT (Foundation for Science and Technology) by the project HC/0077/2009.

The Iberian Peninsula: Portugal and Spain

The two countries in the Iberian Peninsula saw the end of the nineteenth century with the bitter taste of the political humiliation.

In Portugal, after the shameful British ultimatum made following the Berlin conference, an attempted coup to install a Republic took place in 1891 and was defeated; the Portuguese monarchy was going through a period of slow death. This political decline of the monarchy was associated with the political, economic and financial crisis felt all over the country. There was a strong belief that a Republic was imminent and that only the republican spirit could contribute to the complete regeneration of the country, both intellectually and historically.

In the same period, Spain was deeply wounded because of the humiliating military defeats inflicted by the United States and consequent loss of its colonial empire in America and Asia. The country sought to respond to this situation of political, economic and social deep depression. As a consequence of this reaction, a very strong intellectual and civic responsibility movement was born with the main purpose of promoting a profound modernization of Spanish culture, especially at a scientific level. This movement, supported by eminent intellectuals (Ramon y Cajal (1852-1934), Nobel Prize winner in physiology in 1906) stimulated the creation of the *Junta para Ampliación de Estudios* (JAE) [«Board for Advanced Studies»], a very important institution which was responsible for the major transformations in the Spanish scientific renewal. United in humiliation and defeat, albeit suffering different effects (Portugal did not lose its overseas territories), both nations tried to find a remedy for the crisis.

The impact of the JAE (*Junta para Ampliación de Estudios y Investigaciones Científicas*) on the Iberian cultural world was also considerable. In Portugal, scientists and scholars followed JAE's path closely. The Spanish institution was created in Madrid on January 15, 1907; seven months later, the Portuguese government organized a system of scholarships to finance studies abroad, but was unable to transform this initiative into a permanent new organization. The government decree states: «similarly to what several modern nations have done, with proven and enviable success, we will seek to take advantage of the educational experience of more advanced countries in Europe, by sending a large number of Portuguese students to their schools »[2].

The transformation of Portugal into a Republic in October 1910 triggered a number of important initiatives in the educational field. In 1911, the University of Coimbra (the oldest and only university in Portugal over the past centuries) was reformed and the institutions of higher education in Lisbon and Porto were reorganized on a new basis: two universities were founded in the same year in those major cities. Republican reformists assigned the universities a definite number of goals. Among them, the promotion of scientific research, the systematic study of problems regarded as of national interest, and the transmission of culture directly from the universities to other sectors of the population. In spite of financial difficulties, the Portuguese universities supported the graduation studies of few young teachers abroad and some of which went to important European laboratories. Despite these important modifications, the Portuguese government was unable to organize an institution similar to the Spanish JAE with the purpose of coordinating the national scientific policy. It is worth noting that all the plans to reform the universities were implemented in an environment dominated by the old corporation of full professors who kept their old chairs in the new universities.

After the end of the First World War, in 1918, and during the next decade there were several attempts to create a scientific institution capable of promoting a pedagogical and scientific renewal. In 1924, the minister of education, António Sérgio (1883-1869)[3], submitted to the Parliament a diploma to create the *Junta de Orientação dos Estudos* [«Board for Studies Orientation»]. As in previous attempts, the Parliament did not approve the project because of financial restraints and of the differing approaches of the various political groups towards education problems.

Between 1916 and 1924, several Portuguese teachers and students went to Madrid to visit JAE[4] and to collect information about its methods and policies.

Medical doctors were the dominant force in the Portuguese scientific community and it is worth noting the importance of this group and its enthusiastic action for the creation of an institution similar to the Spanish JAE. Two of them were of particular relevance: Augusto Celestino da Costa (1884-1956), full professor of the Faculty of Medicine in Lisbon and his

scientific disciple, and Luís Simões Raposo (1898-1934); both were Ramon y Cajal admirers and had scientific and institutional contacts with him[5].

«Junta de Educação Nacional» – JEN

After the 28th of May 1926, with the country under a military dictatorship with no plans to innovate an education system and suffering from a severe funding restrictions, the Minister of Education, following the orientation of his predecessor, approved in the promulgation of a Decree that created the *Junta de Educação Nacional* (JEN) [«National Board of Education»]. The government assigned the indispensable financial resources for its operation. The main important contributions of «JEN»'s program were «to found, improve or subsidize institutions devoted to scientific research (…) to organize and monitor a grants service to be used in Portugal and abroad (…) to promote locations for the scientific work of the ex-grant holders»[6]. The new *Junta de Educação Nacional* (JEN) was officially created in 1929 with Simões Raposo as its Secretary. Following the Spanish JAE example, the new Portuguese institution concentrated initially on offering research scholarships in Portugal and abroad, with the further goals of promoting scientific research at the higher levels of university education, and the transfer to Portugal of the technologies needed for a better management of the country and its colonies. It also planned to support existing research centers, encourage scientific publications and to promote wider cultural exchanges with foreign countries. The JEN policy of sending a large number of students abroad was an implicit recognition of the inability of the Portuguese universities to produce the graduates Portugal needed to work in pure and applied sciences.

In the beginning of its activity, JEN gave some funding to «institutions, public or private, whether or not incorporated in universities or Technical Schools, provided these institutions showed: (…) that their practice was directed exclusively to scientific research (…) that they had good results in recent years, and that their work was cited or earned the appreciation of national and international experts». The physics laboratory of the University of Lisbon was one of the first group of institutions that received JEN's funding. In 1931, the board of JEN declared that «in future it [JEN] will create or develop laboratories or other centers devoted to new special studies, not yet available in the country, where grant holders recently arrived from abroad can work»[7]. Indeed, some years later, JEN organized several scientific research centers, in the fields of mathematics, natural sciences, philology and history that were integrated in the three Portuguese universities. These research centers fundamental objective was to support the work of returning grant students from abroad and also to receive scholarships to pursue research and graduation. The JEN board was aware that the country was in a «precarious situation, mainly in industry and agriculture, which are technically very poor, and that a sound technical preparation of engineers and agronomists will be a necessary condition to promote the progress of the Portuguese economy». The returning grant students contributed in a very special way to the emergence of new scientific structures that supported technical and scientific research.

Although up to 1934-1935 JEN budgets were, on relative terms, quite limited, they supported 173 scholarships abroad (see table 1[8]). Natural sciences (Biology, Chemistry, Geology, Physics) and Mathematics students was the group that received more scholarships (38 and 50), Medicine and Biomedical sciences deserved the second place with 25 and 30 scholarships. France was the preferred country with 34 and 38 grants, followed by Germany and the United Kingdom; Belgium, Italy, Spain, Switzerland received also Portuguese grant holders. Also a number of small grants were given for shorter stays abroad, of up to three months. During the same period JEN also awarded 90 grants (for periods over than one year) to be used in Portuguese institutions: the first place in this distribution was for medicine with 43 and the second one was for natural sciences (Biology, Geology, Physics and Chemistry) with 40 grants[9].

The «rebirth of a scientific movement»

In the thirties, an important group of young researchers furthered their studies abroad in renowned European universities and laboratories, where some of them were awarded their PhD degree. the University of Paris was the most sought after school for post-graduation studies in Chemistry, Mathematics and Physics. During this period the Curie laboratory received an important group of Portuguese students. Table 2 lists the Portuguese researchers who worked in the Curie Institute[11], also young physicists who studied in other European institutions and the very special case of a Mathematician who gained his PhD in Paris.

The physicist Manuel Valadares (1904-1982)[12] and the mathematician Antonio Aniceto Monteiro (1907-1980)[13] are two paradigmatic examples of a very special attitude in changing the scientific environment when returning to their Universities in Portugal. They were the main players in the «*rebirth of a scientific movement*»[14] which was characterized by a full-time dedication to the research beyond the allotted time for classes, when researchers were university teachers, the maintenance and strengthening of ties with the international scientific community, the publication of their scientific research results in international journals and by a strong commitment to encourage other young researchers with the purpose of creating a research group (replicating their own practice abroad).

---

[10] There were some cases where the same grant was for two countries.

These two young scientists started this movement with a very specific task: to re-unite in the country their fellow colleagues who had studied in Paris with scholarships. This group, the so-called «Physics, Mathematics and Chemistry Group», operated as a private Association whose members were young scientists that had furthered their studies in Paris and senior professors of Portuguese universities that were really interested in promoting scientific research (a very small group of iconoclast full professors). This scientific association promoted in Portuguese universities, open courses on contemporary physics and mathematics topics that were not taught in university graduation courses. This initiative caused a strong perturbation in the conservative Portuguese *academia*[15].

It is important to compare the activities of these two young «scientific agitators» after their return to Portugal which is chronological and briefly shown in table 3[16].

The physics group in Lisbon

Of all these young researchers, the physicist Manuel Valadares is undoubtedly one of the main characters in this story. In a very meticulous and organized way and with total dedication, Valadares built the first Physics Laboratory Group for experimental research in Portugal. An enormous tenacity, the use of a strategic plan and with an excellent talent for organization characterized his work. He never complained about the deficient conditions in which he had to carry out his research work, instead he always tried to do high quality and up to date research in the real conditions he had to face. The strategy he developed with total agreement of the full professor of Physics Lab in Lisbon[17] was, in his own words, the

1940	**Mathematics Seminar becomes the Mathematical Research Center of Lisbon supported by JEN/ IAC.** Five young Mathematicians who started working in this Center went abroad with scholarships (Zurich and Rome).	**The research group on Physics becomes the Physics Research Center of Lisbon supported by JEN/IAC.** Armando Gibert, a young researcher of Valadares' group got a scholarship to study in Zurich.
1943		***Portugaliae Physica*** *(Portuguese international Journal on physics. Ongoing publication to the present day)*
1945	**António Monteiro leaves Portugal for South America.**	
1946		***Gazeta de Física*** *(A physics journal publishing papers on the teaching of physics and on topics such as contemporary physics, applied physics —all aimed at the introductory-level teacher; ongoing publication to the present day)*
1947		**Manuel Valadares leaves Lisbon for Paris**

After returning from France in 1933, Valadares tried persistently to keep strong links with the Curie laboratory and to broaden his connections with the scientific international community network. The scientific results of his research group were always submitted to French scientific journals. In 1940-41 he moved to Italy where he carried out research at the «Instituto di Volta» –Pavia, with Rita Brunetti, from February to May 1940– and in the «Laboratório di Fisica dell'Istituto di Sanitá Pubblica» –Roma, with G. C. Trabacchi, from june 1940 to May 1941. In Rome he made contact with the Amaldi group and established important links with Italian physicists[19].

After 1940, as senior members of a Research Centre financed by the JEN/IAC[20], Valadares and Aurélio Marques da Silva (1905-1965) (another PhD from Paris who worked with Frederic Joliot (1900-1958)) supervised the PhD dissertations of four young assistant professors in three years –*Lídia Salgueiro* (1917-2009) from the Physics Laboratory in Lisbon, *Marieta da Silveira* (1917-2004) from the Chemistry Laboratory in Lisbon, *Carlos Braga* (1899-1982) and *José Sarmento* (1899-1986) from the Physics Laboratory in the University of Oporto–, a very remarkable work, indeed. Because of the communication difficulties during the war and the need to inform the scientific community of their scientific results, Valadares and the group

Total	**59**	**32**	**90**	**10**	

During the war, this Research Centre made serious efforts to support the stay in Portugal of Physicists from France, Italy and Austria who were escaping from the Nazi occupation: Salomon Rosenblum (1896-1959), Guido Beck (1903-1988) and Sergio de Benedetti (1913-1994). The Curie Laboratory in Paris was the link of these three physicists to Portugal, especially in their relationship with two young researchers Mário Silva (1901-1977) (from the University of Coimbra who was in Paris from 1925 to 1929 with a grant of this university) and Manuel Valadares (from the University of Lisbon).

Salomon Rosenblum had a close relationship with both of them (Mario Silva invited him to come to Portugal in 1933) and he had done research work with Valadares in Paris. Beck has been in France since 1937 and during his escape he was informed by French colleagues about the possibility of getting a position in Portugal. Beck had sent a plea for help to Mário Silva in Coimbra through a contact in Paris. During his stay in Portugal he started a cooperation with Valadares (Lisbon Physics Research Centre) and they both helped a small group of physicists and mathematicians from Oporto University to start with the Oporto Theoretical Physics Seminar activity[22]. Sergio de Benedetti, an Italian of Jewish origin working at the Paris Institute of Radium, also sought refuge in Portugal. Physicists and mathematicians from Coimbra, Lisbon and Oporto universities tried to get funding to help these scientists stay Portugal. However, the university was generally resistant to change, extremely reticent in its dealings with foreigners and therefore notorious for its lack in receptivity to academics from abroad bringing new ideas into Portugal. This also explains why the Portuguese academic community never made a great effort to ensure that a warm welcome was extended to renowned scientists fleeing to Portugal.

An unhappy ending...

As we have pointed out, the Portuguese university was generally resistant to change and extremely reticent in its dealings with foreigners who brought new ideas to the country. The great part of Portuguese Academia ostensibly showed a similar attitude towards the young researchers who arrived from a stay of several years abroad. Very few full professors of Portuguese universities were really interested in promoting scientific research and also in supporting new initiatives. This general attitude of the university and the political repressive response of government to the general hope of a shift to a democracy explained the end of the story.

After arriving in Portugal holding a PhD, António Aniceto Monteiro was unable to secure a lecturer position in a Portuguese university because he refused to sign the anticommunist declaration which was compulsory for a civil servant (a very unusual and courageous attitude). In 1945, the Brazilian government offered him a position in Rio de Janeiro and he left

Portugal. The five young Mathematicians, who had started working with him and then went abroad with scholarships, were unable to reopen the Mathematical Research Centre of Lisbon when they returned to Portugal after the war.

The university never gave Manuel Valadares a position of full professor during his near fifteen years of scientific activity in the laboratory of physics; beyond the scientific papers he published in scientific journals, he was the author of a book which appeared, in 1935, in a prestigious French publisher[23]. For Valadares, like for Monteiro, to be a scientist was a cultural attitude towards the world and life, an attitude supported in some philosophical ideas. Firstly, a unitary representation of the world in which science has a fundamental influence on the material, spiritual and moral evolution of humanity; secondly, the supremacy of reality over the ideal, of the objective over the subjective, and of scientific knowledge over the metaphysical; thirdly, the firm belief in man's capabilities and in the power of his rationality. A set of ideas that opposed the political and social orientation of Salazar's *Estado Novo* («New State»)…

After the war Manuel Valadares was forced by Salazar's regime to interrupt his scientific career at Lisbon University, he abandoned Portugal and started doing research at the Joliot Laboratory in Paris. In spite of the distance between Paris and Lisbon, Manuel Valadares continued to participate in the scientific life of the Lisbon laboratory through permanent contact with Lídia Salgueiro, one of his former PhD students and then professor at the Faculty of Sciences in Lisbon.

ALEXANDRE PROCA OR THE INTERNATIONALISM OF PHYSICS DURING THE TWENTIES AND THIRTIES

Martha Cecilia BUSTAMANTE
Laboratoire SPHERE – UMR 7219, Paris, FRANCE
mcbusta@univ-paris-diderot.fr

Abstract

Alexandre Proca (1897-1955) is one of the prominent figures of physics in France between the two wars. He has been a key player in efforts to give to the theoretical physics research a prominent place in the country. In France, as shown by historical studies, physics research was at that time largely dominated by the experimental tradition. Proca also occupies a place in the history of quantum field theory. Author of one of the first doctoral thesis in relativistic quantum theory in France, he proposed the equations that bear his name, Proca equations, which describe particles of spin 1.

From Bucharest to Paris, from engineering sciences to theoretical physics, from theoretical work to the activity of organizing research, Proca followed a singular trajectory whose strongest meaning appears in the light of his "internationalism" (linguistic, intellectual and geographical), but especially in the light of the general scientific internationalism that develops at that time. This is what we intend to show in our presentation.

Proca illustrated in the hard political, intellectual and scientific French context in the thirties and very concretely in the specific context of Parisian world of research. It is marked by great figures (Paul Langevin, Marie Curie, Jean Perrin, Emile Borel ...) and by the emergence of the new Institut Henri Poincaré. Deriving from internationalist projects of the Rockefeller Foundation, the Institute H. Poincaré, where Proca conducts his activities, is devoted to the development of theoretical physics. We will consider these facts to better understand Proca's trajectory and, more general, the ways in which scientific internationalism materializes at European level and in the inter-war period.

Alexandre Proca (1897-1953) is one of the leading figures of French physics of the first half of the twentieth century. Like Jacques Solomon, Leon Brillouin and Louis de Broglie, Proca instigated theoretical research in relativistic quantum theory, especially during the 'thirties. From a point of view relevant to the subject of this symposium, the "internationalism in science", Alexandre Proca is a very interesting individual with a unique itinerary. He is among those scientists who, during the first portion of the twentieth century, chose to foster a career outside their country of origin. Proca was born in Bucharest. A Romanian intellectual declared that Proca belongs to those "Romanian talents who, between the two World Wars, made Paris their second home." In fact, he thought he had something to say in theoretical physics, to use a concise phrase he used to rationalize his migration and his decision to live in France.

What were the reasons for Proca's migration to France? On what political and/or intellectual context was the migration based? Under what conditions did Proca leave his country? What were his intellectual interests? How did he make his way in France? It is on matters of this nature that I will focus this presentation. Questions of this sort shed light on scientific internationalism. I will make some remarks regarding this subject at the end of my presentation.

Let me evoke first of all Proca's life in Romania. It revolved around a technical and practical world. Initially, Alexandre Proca was an engineer, having achieved a degree in the electromechanical section from the Polytechnic school of Bucharest, in the year 1922. With his engineering degree, Proca went to work in the private sector. This allowed him to attain experience abroad, including a trip to the USA in order to visit factories. Proca also had the opportunity to pursue a variety of supplementary scientific activities: in the same Polytechnic school he worked as a teaching assistant. He also collaborated with a local scientific journal. Finally, he was attracted by theoretical work in physics. Between 1920 and 1922 he gave a series of lectures on the theories of special relativity and general relativity. We mention in this context that he was, in particular, well informed about the debate that relativity had generated in France. The debates among the Parisian intelligentsia included the physicist Paul Langevin, the mathematician Paul Painlevé, and the philosopher Henri Bergson, to name only a few. These talks on relativity theory are significant for Proca's itinerary. The reputation that the physicist reached at this time is owed in part to it. This is easily understood. In his complete works published in French and edited in 1988, the author not only describes practical aspects of his theoretical insights, but reveals himself to be a talented promoter of science.[1]

These events at the beginning of Proca's scientific life were near the end of his residence in Romania. In 1923, while he was in rather favourable circumstances, Proca left the country for France. The specific conditions under which he left will not be described here. To understand Proca's migration we should look at the intellectual relations between Romania and France. We do not know if Proca had been to France beforehand. What it is clear, however, is that this country was for him a logical destination. Scholars note that in the early twentieth century Bucharest was called "Little Paris". Historians refer more generally to the strong links existing between France and Romania. It seems that there was a long history of cultural and economic relations that have roots in the sixteenth and seventeenth centuries. At the time of the Enlightenment and much more intensely so during the Romantic era, specialists note, many Romanians made their studies in France. The engineering schools in Paris, especially, welcomed young Romanian students. Proca himself was the son of a former student of the School of Arts and Manufacturing. The experts also speak of the French influence on public institutions in Romania. Historians show that this influence is revealed in all intellectual manifestations, and draw attention to the fact that the French language and literature was deeply influential. They spoke of the existence in the early twentieth century, of the Romanian political and intellectual elite, who were French speaking and Francophile. Proca himself spoke French, as well as German and English.

Thus, by coming to France, Proca ascribed to an apparently well established practice. Other aspects, which do not relate to the links between two countries, but rather refer to French science at that time, were also likely to make Proca's migration to France comprehensible. At the very beginning of the 1920s, France seems, potentially at least, to be a destination object for people who were looking for intellectual landmarks, and especially for new or *avant garde* scientific landmarks. Historians record the prestige of French mathematics between the two World Wars. In physics, there were in Paris a number of personalities who had reached international reputation: Marie Curie, with her laboratory for the study of radioactivity; Jean Perrin, discoverer of the atom in 1910 and who was at the Sorbonne's Physical Chemistry laboratory; Paul Langevin, Professor of Experimental and theoretical physics at the Collège de France, and director of the *Ecole Supérieure de physique et de chimie*; he also lead a laboratory devoted to ion physics at the Collège de France. Finally there was Maurice de Broglie and his X-ray laboratory. All of them were working in the field that Paul Langevin –when participating in scientific meetings such as "Conseils Solvay"– called "the new physics" (*La nouvelle physique*). It was at the time before the First World War. Now, how much was Proca influenced or attracted by these personalities? The question remains unanswered. It is clear, however, that it was with them that the young Proca went to look for a place of work in Paris in the second half of the 1920s.

Proca's Parisian experience. The beginning

We evoke Proca's Paris experience in order to consider his possibility of success at becoming a theoretician. It is apparent that Proca fulfilled the conditions required for being accepted into the Parisian scientific world, or at least those imposed by Marie Curie. To my knowledge, Proca did not have a scholarship. Even though he was trained as an engineer, Proca was nevertheless obliged to start his studies *a Licence ès Sciences* at the Sorbonne. At the end of these studies, from his own testimony, he came to visit Marie Curie, asking her to permit him to join her laboratory. She accepted him personally. It was around 1925. Due to Proca's training and experience in Romania, we can rationally imagine the positive impact his advanced skill set had on Marie Curie. Nothing suggests that he proposed to Marie Curie a specific project.

---

[1] G. A. Proca, *Alexandre Proca.Oeuvre Scientifique Publiée*, S.I.A.G., Rome, 1988.

In the laboratory of Marie Curie, he performed experimental work on beta decay, among other activities. Compton's theory of gamma ray scattering had recently been published, which attracted the interest of Marie Curie. But Proca's scientific activity extended beyond his work with Marie Curie during his early period in Paris. Was it simply a case of someone who was looking for new subjects? Proca focused temporarily on probability theory and its applications taught by Emile Borel at the Sorbonne faculty of sciences. Proca had probably enrolled in this course. This gave rise to Proca's publication of the paper: "On an extension of the concept of probabilities."[2] He maintained very close ties with his homeland; therefore, this paper appeared in a Romanian journal of mathematics. A little work on the theory of the photon illustrates another subject of interest of Proca at the time. It appeared in a collection edited by physicist Léon Brillouin.

A more general statement on the environment in which he lived in Paris explains the diversity of Proca's interests and their nature. Proca attended the faculty of sciences, but in addition he was increasingly divided between the laboratory of Marie Curie and the Collège de France. Proca constantly fed his penchant for theoretical reflection. At Collège de France, as mentioned above, Paul Langevin was teaching theoretical physics. Proca probably attended Langevin's lessons given between 1926 and 1930: "La structure des atomes et leurs propriétés magnétiques et optiques"; "La structure de la lumière et les quanta"; "Les échanges entre la matière et le rayonnement"; "Le magnétisme: récents progrès théoriques et expérimentaux". As with all the physicists who attended them, Langevin's lectures at Collège de France were very important for Proca. Because of the brilliant subject matter, Langevin's lessons attracted the whole of the Parisian élite. Thus Proca had the opportunity to come into contact with such luminaries as Leon Brillouin, Jacques Solomon, Francis Perrin, and Louis de Broglie. Foreign visitors also attended Langevin's lectures, including the physicist Leon Rosenfeld, who around 1929 was beginning a collaboration with Niels Bohr in Copenhagen. Proca met Rosenfeld, too.

So this is an illustration of the possibilities open to a young man who wanted to become a theoretician in Paris. There was not, however, an institutional and academic structure devoted to theoretical physics. In this regard it is interesting to mention how major figures in France at that time become theoreticians. Louis de Broglie had begun in the laboratory of his brother Maurice. Francis Perrin had managed to complete his PhD thesis in an almost pure mathematical environment while working with Emile Borel. Langevin's son-in-law, Jacques Solomon, went to Copenhagen to work with Niels Bohr's collaborator: Leon Rosenfeld. Fortunately for Proca, Institut Henri Poincaré opened its doors in 1929. There, he would become a theoretician.

Proca at the Institut Henri Poincaré

As it is known, Institut Henri Poincaré owed its existence to the philanthropy of the American, John D. Rockefeller. This creation was part of a wider project in mathematics in Europe. Negotiations between the founders had taken place in Paris during the second half of the 1920s. The mathematician Emile Borel was one of the most important founders. Borel attributed to the institute the role that it would play in France: to promote the development of theoretical physics and the "*Calcul de probabilités et ses applications*". Emile Borel was motivated by his interest in physics and applied mathematics. According to agreements reached between the Rockefeller Foundation and the University of Paris, academic positions were created. Thus Louis de Broglie became one of its first faculty members, as professor of theoretical physics, moving from his brother's laboratory to the "Institut Poincaré". About Proca and his arrival at the institute we have only a few details. It seems that it was Marie Curie who advised him to join the institute. We should recall that it was she who introduced him to physics research in Paris. The "Institut Poincaré" would allow him to achieve his aspiration of becoming a theoretical physicist. He began under the auspices of Louis de Broglie to prepare his doctoral thesis on the theory of Dirac. He defended his thesis in 1933. Subsequently, he led the research in relativistic quantum theory that culminated in 1937 with the "Proca equations".

It was intended from the beginning that a series of lectures and conferences by prestigious foreign guests were regularly to be made at the new Institute. Albert Einstein, unable to appear in 1929, nevertheless came in 1930, in which he gave a series of lectures on relativity and the unified field theory. Proca was commissioned to translate them. They were published in French in the *Annales de l'Institut Poincaré*. This journal had just been created. The most distinguished figures in theoretical physics came to the Institute: Erwin Schrodinger preceded Albert Einstein; Niels Bohr, Wolfgang Pauli, Leon Rosenfeld, and Robert Millikan came later.

Now, we discuss Proca and the whole of activities conducted at the Institute during the thirties. It is difficult to know exactly what role Proca played, in particular regarding the general organization of courses. In contrast, we know from a correspondence between Proca and Leon Brillouin, that he was heavily involved in the publication of the *Annales*. Editing of the journal required language skills and Proca had them. From another perspective, the lectures at the Institute and the publication of the *Annales* were for Proca an opportunity to establish contacts with foreign physicists, for example, W. Pauli and E. Schrödinger. In some cases, these contacts became deep and enduring, as we see from Proca's correspondence. The letters exchanged between Proca and Schrödinger discuss such diverse topics as Proca's translation of his wave

[2] See reference 1.

mechanics, purely scientific questions, and so on. Proca's correspondence with his fellow physicists is rich, and this remains largely unstudied by historians. Proca's scientific life at the Institute, though very productive, was far from representing the whole of activities conducted by him during the thirties.

Concluding remarks

It is clear from a general point of view of Internationalism, that Proca's itinerary raises –first and foremost– the questions of geographical borders, of migration of persons, of transfer of skills and knowledge, and of opportunities for candidates through movement. However, was Proca himself heavily influenced by the internationalism of science? Should we place him rather in the context of international migration, in light of awareness of new opportunities for travel offered by the emergence of new means of transportation? I remind you only in relation to this question that it was at the turn of the twentieth century that this movement was first manifested. From another less general point of view, let me make this observation: at the beginning of the twentieth century, France and Romania were two countries that after a long history of inter-connectedness had moved closer together. It made favourable Proca's mobility.

Proca, initially trained as an engineer, wanted to contribute to theoretical physics and chose France as the best place to advance his career, but his goal could not be realized immediately. Conditions favourable to theoretical work really did not appear until the thirties with the creation of the Institut Henri Poincaré. Until this time, he worked in Curie's laboratory and concurrently attended the lectures of Langevin at the College de France. Certainly these experiences prepared him professionally, but there is more to it than that. In terms of scientific openness, they demonstrate the great possibilities of Collège de France and Laboratoire Curie. These were places open to outside countries, almost without frontiers. Let me mention that besides Proca, Portuguese students in the late 1920s and the Soviet physicist D. Skobeltzyn in 1929, to mention only foreign visitors, shared with Marie Curie the scientific and intellectual atmosphere of her laboratory. This benefitted Proca. A recent study about the scientific activity in Portugal, more precisely in Porto and during the Second World War, mentions the encounter between Proca and Portuguese students at Marie Curie's laboratory. We see how significant this encounter was. Proca had failed to enter the United States, but he did seek refuge in Portugal. The links that Proca established with some of these Portuguese students helped him to stay in Porto.[3]

The "Collège de France" and especially the "Institut Poincaré" placed Proca in an international environment. In this context he was a major player in the "internationalist vision of science". He learned to organize himself in international teaching. In 1946, immediately after the war, Alexandre Proca put in place at the Institut Henri Poincare a seminar in theoretical physics, the Proca seminar, which was a huge success. His "internationalist" dimension allowed a whole generation of young graduates to become familiar with the theoretical research in nuclear and particle physics that dominated the scene and continued to evolve. Indeed, presentations on meson theory given by a number of distinguished theoretician guests from abroad such as Yukawa or Peierls, inspired new French theoreticians who dominated science in France in the 1950s and 1960s.

Proca's relationship with the Romanian academic environment had doubtlessly never broken. But, in fact, he did not have time to organize big projects with his country. He died too early. Finally, his Romanian origin caused him problems during the War. In France, this prevented him from teaching, but this will not be elaborated upon here.

BEYOND THE MOLECULAR VISION: UNROMANTIC PERSPECTIVES ON THE HISTORY OF BIOPHYSICS

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 823.

SEEING THE INVISIBLE. THE INTRODUCTION OF ELECTRON MICROSCOPY IN GREAT BRITAIN

Pedro RUIZ-CASTELL
Institut d'Història de la Medicina i de la Ciència 'López Piñero', Universitat de València - CSIC, SPAIN
pedro.ruiz-castell@uv.es

Abstract

During the twentieth century, life sciences experienced notable progress thanks to the development of new and improved instruments coming from the field of physics, such as the electron microscope. However, life scientists originally proved very reluctant to incorporate this new technique into their research. In fact, the development of such a new instrument was a consequence of a general concern in the scientific and industrial analysis of materials. In Britain, it was considerations of the potential uses and applications of the new technique, together with the war context, what highly influenced the development and consolidation of electron microscopy, promoted by a new community of scientists engaged in the study of both organic and inorganic structures.

Introduction

The origins of electron microscopy date back to the late 1930s and 1940s, when it developed around a new and promising instrument with many potential uses and applications in different fields engaged with the study and understanding of microscopical structures. In recent years, historians of science such as Nicolas Rasmussen, Bruno J. Strasser, and Falk Müller have dealt with the successful history of the development of electron microscopy in North America and continental Europe.[1]

In Britain, it was only during World War II that the interests of physicists, engineers, life scientists, businessmen, and science administrators converged towards and favoured the introduction, promotion, and support of electron microscopy. This was partly a consequence of specific scientific, political, and economic aspects and interests that one may recognize in

[1] See, for example: N. Rasmussen, *Picture control. The electron microscope and the transformation of biology in America, 1940-1960* (Stanford, 1997); B. J. Strasser, *La fabrique d'une nouvelle science. La biologie moléculaire à l'âge atomique, 1945-1964* (Florence, 2006); and F. Müller, "The birth of a modern instrument and its development during World War II: Electron microscopy in Germany from the 1930s to 1945", in A. Maas and H. Hooijmaijers (eds.), *Scientific research in World War II: what scientists did in the war* (London, 2009), 121-46.

the context of warfare, including the promising industrial applications of the new microscopes and the successful investigations on bacteria and other biological specimens reported from Germany. All these discourses and approaches favoured the importation of several electron microscopes to be used in such a wide range of investigations and the formation in the 1940s of a new community of scientists who promoted scientific studies under the new instrument and unified techniques of specimen preparation and imaging.

The electron microscope represented a merger of interest between several features such as academic work in different fields, industrial and economic concerns, and political aspects related to the war context. The aim of this paper is to unveil the difficulties surrounding the process of introduction and appropriation of electron microscopy in Britain during the late 1930s and early 1940s. In doing so, I hope to show how the introduction of the electron microscope to scientific research in the country was encouraged by and benefited, not merely a group of life scientists interested in a molecular vision of life, as is generally acknowledged, but a new broad community of academic and industrial scientists concerned with the study of both inorganic and organic material properties and structures.

Early users

The development of electron microscopy is linked to the names of two engineers from the Technische Hochschule of Berlin: Max Knoll (1897-1969) and Ernst Ruska (1906-1988). Using some of the methods and apparatus already developed to some extent for the purpose of cathode-ray oscillography, Knoll and Ruska were the pioneers of the construction of an electron microscope in Germany in the early 1930s. The publication of their results, though still very modest, opened the doors for the development of several independent electron microscope projects, which flourished during the mid 1930s in countries like the USA, Canada, Belgium, France, and the Netherlands.

In Britain, the physicist Louis Claude Martin (1891-1981) began the construction of a combined electron and light microscope at the Imperial College of Science and Technology in London, soon after the German engineers reported their first results. Martin wrote to the prestigious physician and pharmacologist Edward Mellanby (1884-1955), Secretary of the Medical Research Council (MRC), to obtain this institution's financial support. In his first letter to Mellanby, echoing some results obtained in Brussels, Martin pointed out how biological structures could be studied this way 'by means of differential impregnation with compounds of heavy atoms such as osmium'.[2] The use of osmium to fix the vegetal tissues, however, was known to completely destroy the cells. Therefore, Mellanby refused to get the MRC involved in this project to build an electron microscope, considering it to merely be a physical project to be funded, in any case, by the Department of Scientific and Industrial Research (DSIR).[3] In fact, even Martin himself, who had underlined the possible application of this new instrument to the study of biological specimens, admitted in his report that there was no real evidence that the new instrument was of any biological use.[4]

The two-stage electron microscope designed by Martin was finally constructed in Manchester at the Research Department of the Metropolitan-Vickers Electrical Company, which was ultimately involved in the project and undertook the manufacture of the instrument at its own expense.[5] Metropolitan-Vickers was one of the very few British companies capable of producing scientific instrumentation requiring demountable vacuum apparatus. On completion, the electron microscope was transferred from Manchester to Imperial College.

Originally conceived to enable a critical comparison between light-optical and electron microscope images,[6] the electron microscope was used to gain a better understanding of its performance problems, in order to suggest new technical developments to improve the use of the instrument in actual microscopy. In fact, Martin and his team were mainly involved in testing different aspects such as the effects of aberrations produced by the electromagnetic lenses and the adjustments required to centre the electron optical system.[7] Various types of specimen were employed during these tests, mainly thin aluminium and solver films.

Speak, 'A Report on Experimental Work on the Development of the Electron Microscope', *Journal of the Royal Microscopical Society*, 59 (1939), 203-16; and L. C. Martin, 'The Optics of the Electron Microscope', *Journal of the Royal Microscopical Society*, 59 (1939), 217-31.

The electron microscope, which occasionally achieved a resolution of about 100 nanometres with favourable test specimens (at a maximum magnification of 2000),[8] was moved in 1940 from Imperial College to the National Physical Laboratory (NPL), where it was further developed. However, even though it ultimately performed well and produced satisfactory results, this electron microscope never got past the experimental model stage.[9]

Sceptical attitudes and the war context

Despite the interest of some individuals in developing electron microscopy for biomedical applications, dismissive attitudes towards the use of the electron microscope for biological work were relatively common in most European countries during the late 1930s. The main objections were related both to the sense and value of the imaging of microscope structures below the limit set by the wave nature of light in specimens and to the possibility of attaining such a goal with an electron microscope. Biologists believed that even if such microscopic structures existed at all in living tissue, they would alter so quickly that it would not be possible to observe them directly in an electron microscope image. They also doubted that sufficiently informative relationships could be established between such structures and the function of the tissue, such as for example metabolism, breathing or nerve conduction. As Ruska wrote, there was 'an air of resignation that had developed over the course of the previous 50 years mainly because one could not see such fine structures at all in the light microscope'.[10]

The potential uses of the electron microscope, together with the publication of the first results for biological applications, helped transform reluctant ideas that many scientists had about the new technology. But it was not the only reason. At least in Great Britain, the war context was also crucial. The outbreak of the war had brought new concerns and fears to the forefront of scientific research, such as the possibility of chemical and biological warfare. Therefore, it is not difficult to imagine the sense of alarm that spread not only amongst scientists, but also politicians, when the British bacteriologist William Whiteman Carlton Topley (1886-1944) reported in the summer of 1940 to the Ministry of Health and to his colleagues at the MRC the first results for biological research (in particular photographs of bacteria) carried out at the Robert Koch Institute in Berlin with an electron microscope made by the German firm AEG.[11]

Germany was leading the development of biochemical weapons thanks to a secret and decentralized research organization set up during the Weimar Republic that attracted considerable funding during the Nazi era.[12] Such a threat definitively favoured a rapid change in the attitudes of British politicians and scientists to the development and potential uses and applications of the electron microscope.

Charles Galton Darwin (1887-1962) was designated to negotiate on behalf of the British government the supply of seven electron microscopes made by the RCA on lend-lease terms through the British Ministry of Supply. Once the agreement was ratified, seven electron microscopes were delivered to the NPL. They were expected to provide immediate benefits in the study of the microscopical structure of both organic and inorganic material in the particular context of the war years. Once the agreement was ratified and delivery of the seven electron microscopes to the National Physical Laboratory (NPL) was arranged, the Scientific Advisory Committee of the War Cabinet began to produce a tentative priority list for allocating these instruments. The Scientific Advisory Committee began in March 1942 its preliminary discussions on the issue, having decided by then that the first microscope to arrive had to be set up at the NPL,[13] where the experimental model of electron microscope designed by Martin and built by the Metropolitan-Vickers had been employed in tests for metallurgical purposes.

The metallurgical research at the NPL had been deemed of immediate importance with the outbreak of the war, as it was particularly concerned with the structure and failure of metals in practice. Any metallic material that failed in service was

examined by the metallurgy division, the causes for failure being determined as: steel plates perforated by bomb fragments, steel gas cylinders, heavy naval shell, industrial welding, cutting tools, gun barrel broaches, etc.[14]

New imported microscopes

By the end of 1942, five more electron microscopes had been delivered to the following institutions: the Chemical Defence Experimental Station in Porton, a defence research establishment in the Ministry of Supply; the Shirley Institute, belonging to the British Cotton Industry Research Association, in Didsbury; the NIMR premises in Hampstead, North London; Rothamsted Experimental Station, an agricultural research institution in Harpenden; and the Cavendish Laboratory in Cambridge.

As a consequence of the importance given to the applications of the electron microscope to the war efforts, consensus had been soon reached on the decision to send one of the first RCA microscopes that arrived at the NPL to Porton. It was in Porton where different biochemical aspects of war were studied, particularly those of chemical and biological warfare.[15] In particular, intelligence on the chemical warfare capabilities of the Axis powers was scrutinized and new chemical weapons and munitions were developed and trialled. Chemical agents such as phosgene, mustard gas, and different tear gases were industrially produced and weaponized under conditions of secrecy and urgency.[16] Furthermore, practical evaluation of biological warfare had been arranged at Porton by September 1940 under the leadership of one of the foremost microbiologists of the period, Paul Gordon Fildes (1882-1971), who set up a top secret group to undertake these tasks.

The early interest shown by William Whiteman Carlton Topley (1886-1944) in the use of the electron microscope in biomedical work had also made the MRC an ideal and obvious candidate.[17] The electron microscope was finally set up at the National Institute for Medical Research (NIMR) in Hampstead. This may be understood as part of the major effort initiated in the 1920s by the MRC to promote research in what was to become the field of virology, mainly developing new methods to learn more about viruses-ultramicroscopic organisms whose dimensions appeared to lie between those of the smallest bacteria and the largest chemical molecules.

Virology was, indeed, one of the fields that were expected to benefit most. But the identification of certain particles seen in the electron microscope, such as virus particles, was not easy at all. The RCA electron microscope sent to Rothamsted Experimental Station was expected to contribute to the study of the fundamental nature of virus diseases in plants. This field was of increasing interest here during the 1930s, mainly as a consequence of the appointment of the virologist Frederick Charles Bawden (1908-1972) and the biochemist Norman Wingate Pirie (1907-1997), who were especially interested in the study of the physicochemical properties of viruses. Both scientists contributed to the development of electron microscopy in Britain through the spread of new specimen preparation techniques and the improvement of a whole set of new practices regarding the interpretation of electro-micrographs.

The University of Leeds also applied for one of the electron microscopes, which the Scientific Advisory Committee had decided to devote to medical purposes, excluding any other possibilities.[18] It was originally intended for use both in its Medical Department and in the research by William Thomas Astbury (1889-1961) into the constitution of proteins.[19] However, the program was rather weak from the medical point of view and, on some points, showed "elementary misunderstandings of what the electron microscope can be expected to do".[20] It was the name of Astbury, whose X-ray work on the structure of fibres and proteins had mainly contributed to his great reputation, what made Leeds the best option.[21]

Work with the electron microscope was expected to serve as a complement to the X-ray analysis of different materials, including bacterial flagella.[22] In fact, Astbury was very keen to explore how the new technique could be used to solve problems on the border-line between structural and physical chemistry, and fundamental physiological problems.[23]

Electron microscopy also attracted the attention of those involved in studies of the shape and structure of fibres – which had been developed in the late nineteenth century and the early twentieth century by means of light microscopy.[24] Subsequently, the members of the Scientific Advisory Committee decided to provide one of the RCA's electron microscopes to the British Cotton Industry Research Association, an institution founded originally in 1919 to research new technologies of cotton production. This decision was particularly motivated by the stimulus created during World War II for high-performance textile production. In fact, part of the work at the Shirley Institute, where the microscope was to be allocated, had developed into new research, such as the production of fine cotton nylons as a substitute for silk in parachute fabrics.[25]

Good examples of the interest that the new electron microscope awoke outside the British academic world may also be found in the different firms that travelled to Cambridge in the 1940s in order to see the RCA electron microscope in operation. For instance, the United Steel Companies Ltd. visited Cambridge to inspect the new instrument and see what applications of the new technology they could benefit from.[26] Others, like Tootal Broadhurst Lee Company Ltd.,[27] showed a great interest in the potential usefulness of electron microscopy in the examination of fibres.[28]

The story of how the RCA electron microscope arrived in the Cavendish Laboratory provides further evidence of such an industrial interest. Since 1937, the Cavendish Laboratory had been run by the Nobel Prize winner in Physics William Lawrence Bragg (1890-1971). Bragg was engaged in X-ray investigations of different structures, including proteins, and was keenly interested in the application of new forms of microscopy to the interpretation of nature –having even suggested some ideas for an X-ray microscope a few years earlier. The new electron microscope was expected to provide more accurate images of microscopic specimens at higher magnifications.

Bragg began formal enquires about the possibility of purchasing an electron microscope after a meeting of the Panel of the Iron and Steel Federation, which funded and supervised the work in Cambridge on the study of the structure of metals.[29] At this meeting, held on 4 March 1942, the chemist Henry Stafford Hatfield (1880-1966) pressed for the continuation of the long-term research pursued in Cambridge and the short-range war-effort work for the Ministry of Supply. In this sense, he publicly argued for the convenience of acquiring an electron microscope.

One day later, Bragg wrote to Edward Appleton to obtain some of the information on the instrument and ask about the possibility of purchasing one of the electron microscopes produced by the RCA for the Cavendish Laboratory.[30] Appleton was one of the members of the Scientific Advisory Committee that, at precisely that time, were in preliminary discussion about the allocation of the electron microscopes secured under a lend-lease agreement.[31] The electron microscope was sent to Cambridge late in 1942.

Conclusion

The introduction and development of the electron microscope in Britain was encouraged in the late 1930s and early 1940s by a new and heterogeneous community of scientists interested in the structural study of both inorganic and biological material. This new community included not only experimental physicists and biomedical researchers, but also material

scientists and engineers, as well as industrial scientists working in different fields such as metallurgy, pottery, textiles, etc. Some of them were particularly concerned with problems on the frontiers of structural physics, physical chemistry, and fundamental physiology. But in order to understand the process of appropriation and development of electron microscopy in Britain, it is needed a slightly more complex picture in which a whole set of actors, included some outsiders to the academic world and with explicit different agendas, played a crucial role. In particular, the war context seems to have played a crucial role in such a process.

It is difficult to clearly distinguish the limits of professional, academic, industrial, and political dimensions if dealing with the introduction and appropriation of novel scientific techniques and apparatus such as the electron microscope. Moreover, the establishment and later commercialization of the electron microscope in Great Britain required a first step, characterized by the interaction not only of academic scientists from different fields, but also industrial engineers, politicians, private firms, businessmen, etc. All of them were captivated by aspects such as the huge potential that this new instrument seemed to have and an increasing curiosity on what could be expected from it.

The common place provided by this instrument favoured a continuous dialogue between different actors with their own agendas, which included concerns related to aspects such as the acquisition of natural knowledge, the legitimacy for scientific authority, the potential technological applications, and economic benefits. It was the way in which the whole system was consolidated what led to the final success of electron microscopy.

Abstract

*The history of the initial protocols to transfer viral genetic products inducing tumors was greatly facilitated by the availability of continuous cell line of highly contact-inhibited cells (NIH/3T3). During the 70s the teachings of those involved in this research reached some of the Spanish biologists recently arrived in the US. And in the early 80s a significant group of Spanish oncologists developed laborious techniques for the detection of oncogenes, involving the gene cloning of regions where there are aberrations, sequencing and identification of structural genes in the affected loci, and then determination of their role in cancer. Pellicer worked from 1976 to 1980 in cell proliferation and cancer at the Columbia University's Medical Center, College of Physicians and Surgeons. In 1979, Manuel Perucho went to a Gordon Conference on Immunology in New York. Ángel Pellicer communicated him his transfection results. This was why Perucho moved away from Berlin Max Planck Institut für Molekulare Genetik to the US CSHL, and later to Stony Brook. Also in 1979, Mariano Barbacid, from the Laboratory of RNA Tumor Viruses, NCI, Bethesda, went to New York, where Ángel Pellicer communicated him his transfection results. These three molecular oncology research leaders met with oncogenes. After the initial observation that a significant proportion of the tumors scored positive in the fibroblasts used –the NIH 3T3 cells– and that the genes responsible belonged to the ras family, Ángel Pellicer isolated the two main murine genes responsible for the phenotype, N-*ras*, in results presented in 1984. The following year he sequenced the complete coding region of N-*ras*, and suggested evidence for the spectrum of activated mutations in different mouse strains and by different agents. A number of methodical factors affect this historical series of performances. Concept symbols derived from the display of the graphical distribution along time of the concurrent performances reveal the successive shifts of their authors from the Columbia University to the Cold Spring Harbor Lab and the Frederick Cancer Research Center.*

Introduction

In a first approach, the integrated interaction of the viral and cellular genomes is due to L.A. Zilber (1894-1966),[1] the theory of oncogenes was originated by R. Huebner (1914-1998) and G. Todaro (1937-),[2] H. Temin (1934-1994) [3] elaborated the theory of the provirus, D. Baltimore (1938-) isolated the enzyme transcriptase inverse, and M. Barbacid (1949-) activated the first oncogene.[4] The most accurate reconstruction from the true ancestral cancer immunologist Zilber may take into account the importance of the use of cell lines free of sarcoma virus in mutagenic experiments.

In 1969 the third line 3T3 was segregated from the mice embryos in the Swiss/NIH line. This line was to be called NIH 3T3 (after the name of the National Institute of Health where they proliferated). One of the authors was Todaro.[5] The cells gave 20-25 steps to be cloned, until achieving the clone (clone 6) with a particularly high plating efficiency and low saturation density.[6] Later the NIH 3T3 was used mainly to study the viral transformation in tissue- and cell- cultures. The selection of this line for transfection experiments is conditioned by a high efficiency in the integration and fixation of the exogenous DNA in the genome of the NIH 3T3 cells.

The considerable interest that the discovery that an ample variety of tumor cells contained activated *ras* genes had, was detectable through gene transfer in NIH 3T3 cells, and displays the work by Barbacid in August 1983.[7]

This work was presented to the US Natl Acad Sci on April 1983 by the 1953 Nobel Prize Severo Ochoa, who also selected to present there on July 1985 a development on human adenocarcinoma cells of previous NIH 3T3 results, associated to the detection of point mutations authored by M. Perucho.[8] [9] The point mutation malignant acquisition responsibility discovery was the reason after which Barbacid was awarded in 1988,[10] but a carcinogenic induction of *ras* oncogene activation was also obtained under the responsibility of A. Pellicer, being I. Guerrero his postdoc.[11]

Ángel Pellicer, professor in the NYU Dpt of Pathology from 1980, worked with animal model systems of carcinogenesis, by using *ras* genes because of their great clinical relevance. Constantly in contact with Spain through the postdocs training, he admitted Isabel Guerrero as a Fellow of the Spanish High Research Council in 1983.[12] The discovery was that a significant proportion of the tumors scored positive in the NIH 3T3 focus forming assay, and the genes

[12] Other postdoctorals with prof. Pellicer have been Claudette Boni, Alfredo Villasante, Javier Leon, Elizabeth Newcomb, Joan Berman, Timothy Thomson, Montserrat Corominas, Ramon Mangues, Renata Schiavo, Guillermo Saez, Rosario Oliva, Javier Santos, Antonio Garcia-Espana, Juan Sanchez-Arias, Marcos Malumbres, Neus Ferrer, Su-Ying Lu, Quixia Lan, Inmaculada Hernandez, Yixing Li, Ignacio Perez de Castro, Laura Martello-Rooney, Marta Benet, and Raffi Suzme.

responsible belonged to the *ras* family. After the initial observation, the two main murine genes responsible for the phenotype, N-*ras* and K-*ras* were quickly identified. The following year Pellicer sequenced the complete coding region of N-*ras*, identified the activating mutation and indicated that in some tumors there was loss of the normal allele, suggesting that the wild type copy (proto-oncogene) was exerting some restraining effect on the action of the activated version (oncogene). Further studies continued providing evidence for the spectrum of activating mutations in different mouse strains and by different carcinogenic agents.

The Spanish team with which M. Barbacid solved the question that served to establish the molecular basis of human neoplasia was formed by E. Santos, D. Martín Zanca, and V. Notario. The Spanish research group conducted by A. Pellicer involved V. Corces, P. Calzada, A. Villasante, and A. Pellicer. M. Perucho, working with a team that included as Spanish collaborators C. Almoguera, C. Lama and J. Jordano, afforded the characterization of human and murid cellular oncogenes and provided a method to detect mutations in transcripted genes. A previous communication to this conference reported on the constitutional history of these three groups.[13]

But all these experiments arrived to function just because of the fortunate circumstance that the NIH 3T3 cells were not normal at all, but that they already had accumulated a great number of genetic alterations subjacent to the gradual process of neoplastic transformation. They needed one last push, provided by the dominant oncogene.

Scientific agenda of Ángel Pellicer

The Spanish immunological tradition, on the base of technical applications of these cells, started with J. Salas,[14] the doctoral advisor of M. Perucho, on DNA binding proteins from hamster fibroblasts, normal or transformed by oncogenic retroviruses. Salas was involved during his post-doctoral fellowship at NYU, in the early seventies, with H Green, the creator with G.J. Todaro of this cell line.[15]

In the mid-eighties, Ángel Pellicer's research agenda is represented in Fig. 1.[16] The general topology of this picture differentiates the upper zone, methods used along the researches, from the lower zone, aims and results obtained. As observed by the colors used, all the articles were the result of research supported by governmental programs. Criteria of gene purification and cell-transformation observation on animals, like mice, served to experiment with mutations in oncogenes. A fainter intensity in the visualization of terms, as the corpus is associated with dates, reflects superimposed information that reflects less disseminated researches. The structure of the tree is hidden in the center, but the clades obtained at the two tips of the main branch substantially shows the chemics vs. radiation carcinogenic procedures.

With Ángel Pellicer [17] it must be said that "until 1977, the methods of gene transfer were successful only when DNA of low complexity was used", and that "subsequent improvements made the transfer feasible using total vertebrate and mammalian". Pellicer's historical three viral positive timidine kinase colonies were obtained by using the mouse Ltk- cell line, one of the cell lines at this date that possessed exogene DNA incorporation and subsequent stabilization efficiency high enough to allow gene transfer by using total cellular DNA, with the efficiencies reached by Michel Wigler's modifications of the original method. The other line was NIH 3T3. The experiment by Pellicer conclusively attained the theoretical efficiencies of the minimum value in need to transfer a single copy gen; and in contrast with the first successes of the sixties this experiment was reproducible.[18]

A result gene transfer by using total mammalian DNA was obtained by Pellicer in the Columbia University in 1978.[19] Predoc relationships in Madrid were crucially extended by Pellicer at Columbia on transfection protocols. As in 1979, Pellicer received Barbacid from Bethesda and Perucho from Europe in New York, and he transcripted for both his friends the

"ownership" of the transfection experiments in the NIH 3T3 cell lines. The next year (1980) came with Pellicer as tenured professor at the NYU Dpt. of Pathology, a tenure in the NYU at Stony Brooks for Perucho and a new cellular and molecular biology lab at NCI with Barbacid at its head.

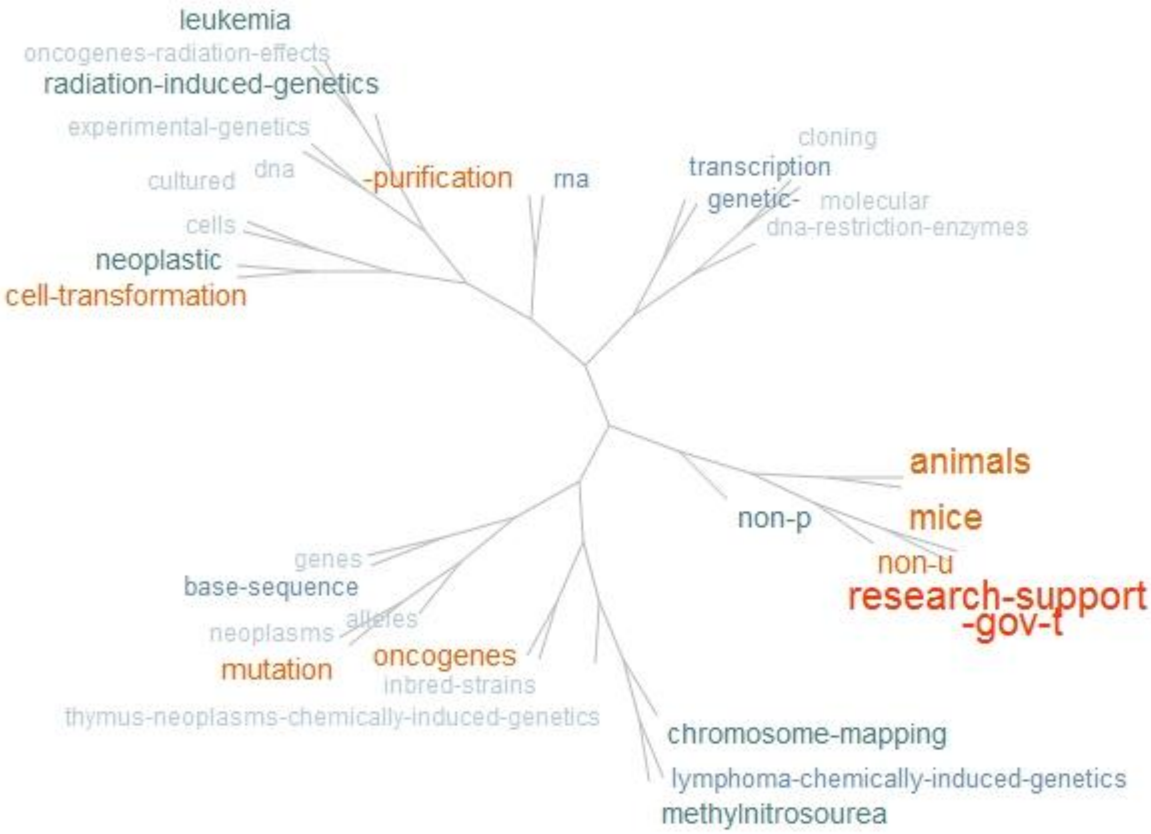

Fig. 1: Maximum likelihood unrooted tree of the tumors scored positive and the genes responsible of it, discovered by Ángel Pellicer.

Once they knew what they wanted from Pellicer, in 1979, how to make growth fibroblasts after successive transfer associated with malignant properties in vivo by using NIH 3T3 cells … all three molecular oncology research groups led by Spaniards decided to identify and isolate human oncogenes through the use of transfection techniques.

In 1982, both the groups of Mariano Barbacid and Eugenio Santos within the National Cancer Institute and the groups of Michael Wigler and Manuel Perucho at the Cold Spring Harbor Laboratory found the oncogene of the T24 line of human bladder carcinoma cells. For his part, Pellicer decided to work in the identification and isolation of murine oncogenes also using transfection techniques in his own lab at NYU Dept of Pathology from 1980.

In the heat of the argument developed by Szybalski,[20] and through his involvement in the integration by cotransformation of all the donor cell genome into recipient chromosomes, the question of whether or not spontaneous neoplastic transformation of 3T3 cells were responsible for unstability by transfection led to met oncogene.

Created in the context of 3T3 cells and at the same time, as a reference scenario for how experiments can "go",[21] 3T6 cells (a line established by transfer of 3 x 10^5 cells to new capsules each six days), were used in 1980,[22] in an ongoing

[20] In 1964, Szybalski reported, by working with a single cell derivative of the Detroit-98 line, originally obtained by nonmalignant human sternal puncture, that the mutant phenotype, the obtention of malignant clones, is determined by the tissular differentiation specific conditions. See Szybalski, W. (1964) !Chemical reactivity of chromosomal DNA as related to mutagenicity: studies with human cell lines". *Cold Spring Harb Symp Quant Biol*., Vol. 29, pp. 151-159.

study of molecular genetics conducted since 1978[23] at the Molecular Biology Center, Autonomous University in Madrid. The Jesús Ávila group worked in the characterization and analysis of the neuronal proteins associated to a component of the citoskeleton, the microtubules.[24] The 3T6 cell line was treated with the help in chromatin preparation of I. Guerrero.[25]

A systemic interpretation of this scientific community

A strictly increasing process defines the cumulative monotonicity of scientific authority in terms of single-peakedness. It is what can fix the attention on the close competition in the race for oncogenes between the three core members of this Spanish community in the US, Barbacid, Pellicer and Perucho. This relation between individual careers consists in being continually approached, as source authors and as cited authors, by the dynamics of the scientific community.[26] A number of interacting processes can be advanced, each embedded in Fig. 2.

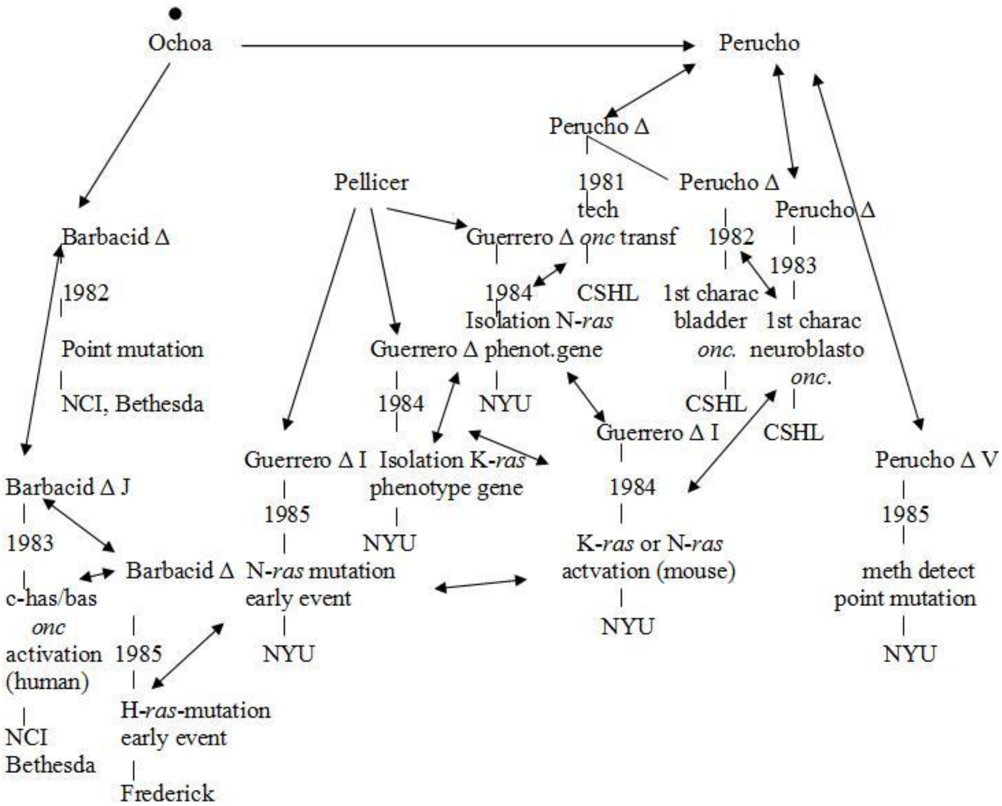

Fig. 2: Schematic view of the way in which Spanish researchers produced mirror symmetrical results in US universities and scientific organizations. Among the three research teams racing for oncogenes. *V*'s and *J*'s symbolize the articles that were presented by S. Ochoa to US Natl Acad. *I*'s illustrate the track of the M. Heidelberger presented group. The small deltas, *Δ*, represent NIH 3T3 cell cultures used to obtain cleavage. Two SCI research fronts are present, 83-1740 "Oncogenes and the genetics of human cancer; viral

transforming genes and their DNA structure" (left side), and 84-4046 "Characterization of human and murine cellular oncogene" (right side).
Abbreviations: CSHL –Cold Spring Harbor Laboratory; NYU –Department of Pathology, New York University Medical Center; NCI –Laboratory of Cellular and Molecular Biology, National Cancer Institute, Bethesda, Maryland; Frederick –Developmental Oncology Section, Frederick Cancer Research Facility, Maryland.

Two research fronts are present here, 83-1740 "Oncogenes and the genetics of human cancer; viral transforming genes and their DNA structure", and 84-4046 "Characterization of human and murine cellular oncogene".

Negative differences separate the two major groups of scientists that define the population of authors inside the program. It means that the problem requiring much more authority than they had assigned, continual competitive behavior linked their productions. Although they did not publish so much in all these years, they were also consistent with the modelled research program. They were "underqualified" as source authors, although "fair" as cited authors. They are Guerrero and Pellicer.

On the question of how much affects individual scientists or its constituent parts (groups of scientists) in this demography, the fact is that only a woman (Guerrero) is allocated to treat the program. This knowledge must be described as an insularity that requires a distortion of the original structure before its narrative can be fitted neatly into place.[27] Figure 2 provides a sketch of this social power process.[28]

Conclusion

The competing oncogene theory, by Robert Huebner and George Todaro, hypothesizing a genetic rather than an infectious mechanism for cancer, and Temin's evolutionary protovirus hypothesis were within the scope of the biology performed in Spain from the early seventies, when José Salas was involved during his post-doctoral fellowship at NYU, with H Green, the creator with GJ Todaro of the NIH 3T3 cell line. Also tumor virology before 1965 had in Francesc Duran-Reynals (Barcelona, 1899 - New Haven, 1958) one of the major figures in the attempt to establish the connection between tumor virus and ordinary viruses. And so it should not be assumed that the viral-genetic concept, which develops the insertion of a viral genome into cellular one, did not exist as early as in the 1920s. It follows that when a new molecular concept of tumor growth was advanced describing cancer as dysregulation of individual genes, a unifying concept of genetic cell abnormalities as a central determinant of cancer emerged from several Spanish leaders of US laboratories in the early 1980s.

To be true, in terms of exogenous and endogenous factors which do trigger cellular oncogenes, the new carcinogen theory worked with a cell line (NIH 3T3) with a good number of genetic alterations subjacent to neoplastic transformation. As trained in chromatin patterns, Isabel Guerrero managed to be in profound understanding of 3T3 cells in Spain, through her involvement in the molecular biology of a component of the citoskeleton, the microtubules. By the hope that in spite of the bias introduced in the analysis by the method of detection, derived from the hazardous amount of previous infection behind NIH 3T3 cells, she integrated A. Pellicer lab in the NYU, in the race for oncogenes that occurred in the mid-eighties. To work under the assumption that 10-15% of all the human tumors analyzed contained activated ras oncogenes. That indicated that it constituted an important biological event and that its relevance was not overemphasized by the selection of experimental systems.

Two of the main competitors were M. Barbacid, a Spanish chemist that started his virologist work with S. Aaronson, and M. Perucho who had work with M. Wigler in plasmid rescue and gene transfer.

The selective controversy surrounding the NIH 3T3 cells made them a revealing tool perceived as a frontier associated to malignant properties in vivo. In connection with signaled results from the labs of Barbacid at Bethesda and Perucho at Stony Brook, after previous successes well reported by S. Ochoa at US Natl Acad of Sci. Under the auspices of Pellicer a unique role for oncogene N-*ras* in mammals hematologic malignancies was suggested. So answering the question of whether it were the cultivated cells that activated their gene after transfection while a different oncogen was operative in primary tumor cells.

By providing additional evidences in favor of *ras* gene activation in early stages, Pellicer supplied robust support to the hypothesis that *ras* mutation is the primary event in carcinogenic models. He also reported on thymic lymphomas in favor

of genetic arguments linking the mutated version of *ras* genes with tumor development and against claims that *ras* genes are activated by truncation and not by point mutation. As contributing in favor of γ-radiation as a source of oncogene mutations he crucially intervened in the debate on mutation specificity for a carcinogen.

The inestimable position of Spanish biologists, in touch with NIH 3T3 cells from its inception, made them technically robust in the search for *ras* oncogenes. A medical doctor, Ángel Pellicer, activated and characterized the genes involved in point mutations by using viral transforming genes obtained through transfer methods developed by himself, first in Columbia University and later in the Dpt of Pathology, NYU. The responsibility for the initiation or progression of tumors, and the issues of mutation specificity have been his successful path to solve the dialectic between the chemist and the biologist in the first steps of molecular oncology.

Abstract

As part of a larger project focused on producing a History of the Popularization of Science and Technology in Portugal, my aim is to find out how scientific knowledge reached the common people, using newspapers as the main source of information. This research is being developed in the project «Reading newspapers: An open window to representations of Science and Technology in the Portuguese Press (1900-1926)». Considering the population's limited access to written material, nevertheless each newspaper could be read daily by an estimate 30,000 people in Lisbon, which places this source as probably the most widespread vehicle to divulge the latest scientific news at the time to an unspecialised audience.

In times of health crisis, newspapers are particularly important sources to access the type of information and advice given to the public and the sanitation measures taken by the authorities. In this paper the goal is to compare several epidemics which scourged the world during the nineteenth and twentieth centuries, by analysing their impact in Portuguese newspapers. It is also our goal to contribute to a larger conscience of the reality of everyday life. Social historians have studied the *History of Private Life* and have produced important books on the subject, especially since the works of Philippe Ariés and Georges Duby in 1985. But this research on the popularization of science hopes to improve these studies, with our findings on how and when technologic discoveries and scientific knowledge were first introduced into people's lives and the way they came to be used by society. Regarding disease, hygiene and epidemics, we hope our contribution on the subject shall help us realize the real difficulties posed on the life of people of every class. Whoever lives in our contemporary "civilized" society probably has no idea of life without vaccines and penicillin, and children dying as a part of everyday life, without even the right to mourning or sadness.

The following mainstream newspapers were thoroughly researched, in order to transcribe all the news on science and technology:

Lisbon:

- *Século*, 1855 (another newspaper with the same title was published from 1881 to 1977).

- *Diário de Notícias*, whose purpose was "to be of interest to all classes, accessible to all purses and understood by every level of intelligence", 1864.12.29 to present.

Oporto:

- *O Comércio*, 1854.06.02 to 2005.07.30. On 1856 its name was changed to *O Comércio do Porto*.
- *O Eco Popular*, 1847 to 1860.

No doubt, in late nineteenth century Portugal, society references, whether they were political, economic of scientific, originated in the media and in the people who wrote them. And all these newsmen shared a tendency for rational and clear thought, as well as an emphasis on science and knowledge with practical utility, and an optimism regarding mankind's capacity to dominate nature and understand the world.

Simultaneously, the scientific community understood the need to divulge its recently acquired knowledge. As scientists were becoming professionals and boundaries were established between them and the public, they also realized that the recognition of their work was necessary for the recognition of their own new professional status. Technological improvements were meant to be used by a large number of people, otherwise they were meaningless. Therefore, they had to be divulged to a wide audience. Regarding medicine, and particularly in times of epidemics, divulging information became a matter of survival, for prevention was the most important means for dealing with a health crisis. Throughout the nineteenth century, the time of the great pandemics, the hygienist discourse was used as the prime way to bring medicine into public life. And authorities used this new resource to fight epidemics, introducing it into official reports which were published in generalist newspapers and pamphlets. Otherwise they would have lost the battle.

Our research focuses on collecting news and advertisements that reveal the scientific knowledge of the time. A large database was built and the news and ads on science and technology were classified according to a classificatory grid, which includes the following themes: Science; Science Education; Exhibits / Conventions; Museums; Personalities /Individuals; Publications on science; Accidents, risks and anomalies; Sanitary science / hygiene, health and medicine; Scientific Institutions / Societies; Technology / Innovation; Travels/ Scientific Expeditions.

Advertisements were also an important source of information, because they were fundamental for educating this early audience. Advertising is an element of progress, of economic and social development. It orients, it supplies information, and it spreads culture, hygiene habits, elegance and good taste. It generates markets, increases demand, intensifies production and lowers prices.

Oporto was particularly affected by epidemics. In the nineteenth and early twentieth century the second Portuguese town presented special conditions for the spread of epidemics, because it was suffering a process of industrial growth and it had a mobile population living in the worst possible conditions as far as hygiene was concerned. There were some neighbourhoods called "islands" where there were concentrations of factory workers which rotated on the same bed and the filth and misery were considered extremely dangerous on all official reports. Every news described Oporto as an infected city with deplorable sanitary conditions.

In sum, these were the major epidemics of the time in Oporto and the amount of scientific knowledge about them (table 1).

The cholera **morbus epidemic** in 1855 (which spread throughout the entire country and was followed by yellow fever in Lisbon in 1857), the **bubonic plague** in 1899, in 1918 **typhus** and **Spanish flu**, and later in the 1980s the AIDS epidemic. In 2009 the H1N1 flu was declared a pandemic and there were prevention measures being encouraged and enforced everywhere, but the main issue remains the same: **hygiene**. This an especially important concern now that penicillin is facing multi-resistant bacteria and has proven ineffective with viruses. Prevention measures were always fundamental and both in the nineteenth and the twentieth century the scientific community has tried hard to educate the people, through the press, repeatedly providing important information. Teaching people how to prevent disease by explaining hygienic procedures has been a constant concern in the press and other more recent media in periods of health crisis. News on the subject reveals the state of the art of medical science in each of those periods. It also reveals the importance given by health authorities and journalists to the publication of the most recent discoveries and adequate hygiene procedures to prevent the spread of the epidemics. This is an important subject that can contribute to the debate on the dissemination of science and technology and assert the place that Portugal, a peripheral country, occupied in the European and North American scientific community in the last two centuries. It was not that far apart from the so called more developed countries, because it was an active participant in every international sanitary conference and because newspapers reveal that Portugal was up to date with every scientific and technological development. As least in knowledge, even if sometimes it was not properly applied.

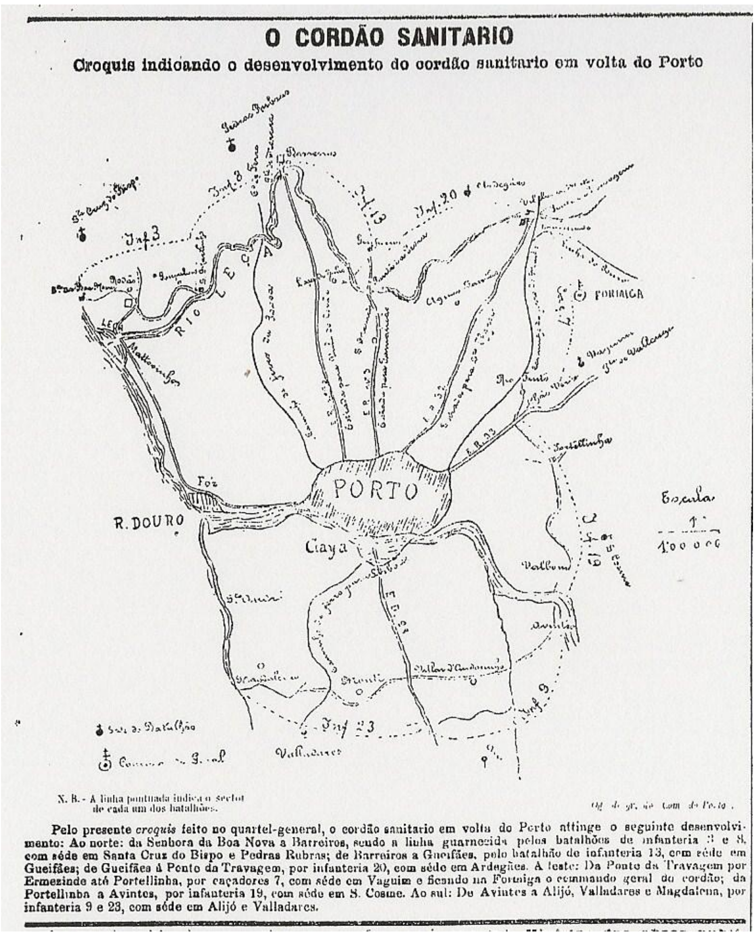
We can observe an increase in the scientific knowledge, particularly in the causes for the transmission of the diseases, and the prevention measures. Nevertheless, treatments were still scarce and the mortality was huge, even when the virus, bacteria and bacillus were identified.

Regarding bubonic plague in 1899, authorities established a sanitary cord around Oporto (see figure 1).

Table 1.

Oporto's Epidemics	Cholera morbus	Bubonic plague	Typhus	Spanish flu	Smallpox
Date	May 1855 – 1857	June 1899 – January 1900	December 1917 – August 1918	June 1918 – December 1918	June 1918 – December 1918
Death toll	22.700 all over the country	111, out of 326 cases	278, out of 2.781 cases	59.000, but later studies indicate up to 135.257	Unknown
Mortality rate	45 per cent	34 per cent	10 per cent	9.8 per thousand of the entire population	Unknown
Causes	Unknown	Bacillus discovered by Yersin and Kitasato Shibasaburō	Bacteria of exanthematic typhus, identified by H. T. Ricketts and Stanislaus von Prowazek	Partly identified, its virus was still ignored	Smallpox virus, identified by Edward Jenner
Supposed causes	Misery, poor hygiene, excessive behaviour, bad eating habits, miasmas, terror	Poor hygiene, misery, fleas, mice, “a microbe”, excessive behaviour	A virus transmitted by lice, lower classes, poorly housed and fed, particularly beggars and criminals	A bacteria, misery, lack of food	
Transmission	Unknown, contagion denied, food, water	Fleas, from mice; through the skin, the nose and the mouth	Lice	Air; First World War, military and farm workers migrations	Air, skin
Sanitary measures	Isolation of the sick and of the entire city, quarantine, hygiene, special hospitals, markets prohibited, schools closed	Isolation of the sick and the entire city, hygiene, special hospitals, markets prohibited, disinfection of buildings and clothes, compulsory baths, sanitary visits with the police, travelling and passengers inspection, children hunting for mice, face mask	Removing lice, body, clothes and house hygiene and disinfection; compulsory public baths and house burning. Isolation of patients and their family and neighbours; house calls (sanitary visits) by health delegates and the police, schools closed.	No known prophylactics, general hygiene and medical assistance, isolation in hospitals. Schools closed, no exams in the universities, markets and fairs prohibited, compulsory notification of the disease. Individual prophylactics: mentholated or salted gargles. Prescriptions for the poor are free. Charitable and well off members of the communities should be encouraged to create private care comities.	Vaccination

Oporto's Epidemics	**Cholera morbus**	**Bubonic plague**	**Typhus**	**Spanish flu**	**Smallpox**
Treatments	Specific treatment unknown. Spirit of camphor, scrubbing the patients with warm salt water, spirit drinks, spearmint, iodine, leeches	Yersin serum	Unknown. For removing lice: petroleum, turpentine, benzene applied on the body; burning sulphur was used for clothes and whitewash for houses.	Specific treatment unknown. Drugs: aspirin, quinine, ammonia, purgative salts, caffeine, camphor oil, mustard and flax seed, borage tea, sodium sulphate in lemon juice with magnesium, anti-pneumococcus serum, sodium benzoate, tolu balsam, benjoim, intravenous injections of glucose, sugar and proper nourishment.	Unknown



O CORDÃO SANITARIO

Croquis indicando o desenvolvimento do cordão sanitario em volta do Porto

N. B. - A linha pontuada indica o sector de cada um dos batalhões.

Pelo presente *croquis* feito no quartel-general, o cordão sanitario em volta do Porto attinge o seguinte desenvolvimento: Ao norte: da Senhora da Boa Nova a Barreiros, sendo a linha guarnecida pelos batalhões de infanteria 3 e 8, com séde em Santa Cruz do Bispo e Pedras Rubras; de Barreiros a Gueifães, pelo batalhão de infanteria 13, com séde em Gueifães; de Gueifães á Ponte da Travagem, por infanteria 20, com séde em Ardegães. A leste: Da Ponte da Travagem por Ermezinde até Portellinha, por caçadores 7, com séde em Vaguim e ficando na Formiga o commando geral do cordão; da Portellinha a Avintes, por infanteria 19, com séde em S. Cosme. Ao sul: De Avintes a Alijó, Valladares e Magdalena, por infanteria 9 e 23, com séde em Alijó e Valladares.

Fig. 1: “The sanitary cord”, *O Comércio do Porto*, 1899.08.26.

During this period many houses were burnt down. Compulsory baths were established for the lower classes, in public baths that were built for that purpose, and children were encouraged to hunt for mice, to deliver them in police precincts, and they were paid for them: "big rats 20 cents, small mice 10 cents each".

As in other earlier epidemics, many scientific international reports on the disease were transcribed and commented upon in the newspapers.

And one Lisbon doctor even invented a prophylactic mask to avoid the transmission of the plague through the nose and the mouth (see figure 2). It was supposed to be used by doctors and nurses dealing with plague patients and the device should be covered by cotton and gauze, imbibed in an anti-septic solution. This was quite an innovation for it was only in 1918, during the influenza, that the use of face masks became popular in Europe.

o algodão e a gaze caem sem ser preciso tocar-lhes, mandando-se queimar, no passo que as hastes metallicas se desinfectam logo a uma

Mascara prophylactica de metal

Quadrado d'algodão revestido exteriormente de gaza embebido n'uma solução anti-septica

Fig. 2: *Diário de Notícias*, 1899.08.24.

Spanish doctors went to Oporto to study the disease and wrote reports that describe the entire work done during the epidemic. Their journey was also reported on the news. They were Jaime Ferran, Frederico Viñas y Cusi, Rosendo de Grau and Federico Montaldo. Regardless of the knowledge of the disease, and the existence of the Yersin serum, that came from the Pasteur Institute in Paris, one of the main doctors who were handling the crisis died from the plague: Câmara Pestana, the Director of the Bacteriological Institute.

In 1918 there was still a typhus epidemic when the first cases of influenza arrived in Portugal from the Spanish border. The first news in Portuguese newspapers concerned the disease in Spain, which hit King Alfonso XIII and the Portuguese ambassador in Madrid Dr. Egas Moniz, who later won the Nobel Prize of Medicine (1949). The first report by Professor Ricardo Jorge warned people about the speed of the contagion. There were no known effective prophylactics, other than general hygiene and medical assistance to sick people, preferably isolated in hospitals.

Ads reflected hygiene concerns, with high incidence on drugs, soaps and disinfectants and even wool coats to avoid the cold, all of them with large titles with the words "flu" and "epidemics" on them. For example, there was a cough syrup which was usually advertised as good for cough, for tuberculosis patients, and others. Now it was good for the flu and bronchitis and pneumonia.

The epidemic hit its peak on October 1918. Even though newspapers continued to report how benign it was in the cities, in order to prevent panic, letters from the correspondents on the countryside, published on the same page, described the amount of orphans and the "painful", "dreadful" and "frightful" disease, together with "extreme misery" and "prolonged suffering".

It is also important to notice that private assistance to the victims and their families was one of the major sources of social welfare at the time, and newspapers were an important factor on that matter. *Diário de Notícias* was able to gather 12,000$000 in two weeks, after having already received 80,000$000 on the two previous months for the prisoners of war. Public figures called rich people to charitable actions and advised them to create committees and solve the problems. And they contributed with their own money for actions that the State could not provide.

At the same time, smallpox had been there, but its intensity increased in June all over the country, particularly in the north. The big concern was vaccination. In 1918 vaccination was not compulsory by law, but was compulsory in practice, because people could not work or go to school without taking it, a rule which still applies in the present. It was posted in every neighbourhood that "no individual over 8 years old may go to school, or work in a workshop, factory, shop or industry, take an exam or public office, without proof of vaccination, revaccination, or having suffered a smallpox assail in the last 7 years. School principals and industry or commerce directors are responsible for enforcing this law, or they shall be fined".

The vaccines were administered for free in health delegations all over the country, and also by the Red Cross. With the 1918 epidemic many new vaccination facilities were created and it was also administered in schools, asylums, prisons, police precincts and other gathering places.

However, these periods of epidemics were not so different from the rest of the time. And this can also be found on the news: sanitary bulletins were printed daily on newspapers and they listed the cases that were reported to medical authorities (which were certainly just a small fraction of the total amount). An average citizen, in the course of his or her existence, would most certainly suffer one or more of the endemic diseases that assailed and killed people until the mid-twentieth century, when vaccines and penicillin were made available to most of the western hemisphere: smallpox, leprosy, tuberculosis, syphilis, typhoid fever, malaria and other intermittent fevers, poliomyelitis, rubella, measles, diphtheria, scarlet fever, tetanus, meningitis, whooping cough and the itch (*sarna*). And also the seasonal influenza, gastritis, and the occasional hydrophobia (rabies), leishmaniosis, lyme disease (transmitted by ticks), brucellosis (transmitted by sheep) and anthrax, formally known as carbuncle (often transmitted by cattle). To these we can add the so called social pathologies, such as alcoholism, which weakened the race (Correia 1938).

Even in normal times there were regular news and ads concerning all the other diseases, such as tuberculosis and its treatments, sanatoriums and spas, research and new drugs, and many others. Therefore, throughout the entire period that is under investigation, news and ads on health and hygiene always had the highest percentage among science and technology news and ads, and reports on diseases and treatments were prevailing.

Therefore we can imagine the fear people lived in. Not only in periods of epidemics, but in everyday life. In the newspapers we find reports on panic attacks and terror caused by the epidemics, generally because of the unknown factor, but also reports on wild dog and wolf attacks, which passed on rabies and entire families ended up dying. This was surely the cause for our mythology on wolves and children and the fear associated: not exactly wolves eating children, but wolves and wild animals transmitting rabies. During the cholera epidemic, terror was even considered one of the causes of the disease.

Hospitals were a particularly frightful place and there were people who chose suicide over going to the hospital, when authorities came to take them to isolation. During the 1899 plague there were riots in the streets when the police and the army were called to force the sick people and their relatives and neighbours to go to the hospital. And during the typhus epidemic in Oporto, a servant at a hotel was diagnosed with the disease and was told he was meant to go to the hospital. He was so horrified that he shot himself in the head.

Concluding remarks

I should like to conclude with a reference to hand washing, after having showed the interest in face masks:

1. As early as 1854, in the beginning of the cholera epidemic, the use of gloves by doctors is referred to as nonsense.
2. During the bubonic plague epidemic there is only one reference to hand washing on official reports. One doctor, a surgeon of the municipal guards, advises the military personnel that in case of contact with a sick person with the suspicious disease, one should immediately proceed to a long hand wash with hot water and soap, followed by disinfection with vinegar and lemon.
3. The Portuguese consul in China, speaking from his experience on a country where this disease was endemic, advised people not to shake hands with everybody and wash them often with energetic disinfectants (*Diário de Notícias*, 1899.08.21).
4. This was also the first time ads wrote about contaminated objects and the need to wash hands with a bar of soap that disinfects them. There is no doubt that advertisements had an important educational value for newspaper readers, in a time when not even doctors put hand washing as a priority of disease prevention in official bulletins.
5. In 1899, an official report by Dr. Ricardo Jorge: hands shall be washed with a disinfecting solution; if there isn't any, hot water shall be used, with soap, or they shall be immersed in vinegar or alcohol. Do not forget meticulous cleaning of nails with a brush. Clothes shall be disinfected with lye or copper sulphate.
6. In 1918 hand washing was still not a priority. During the typhus epidemic there were compulsory public baths and clothes disinfection with burning sulphur. But the only reference to hands is found on a medical report which includes a list of disinfectants and a reference to applying lotions on the most exposed parts of the body, such as hands and feet. Those lotions should be made of mentholated vaseline and camphor oil.
7. The only reference made to hand washing during the Spanish Flu was not by Professor Ricardo Jorge, the National Director of the Health Department, in his official reports, but by Dr. Giraldino Brites, an attendant at Lisbon's University Hospital, who interviewed Dr. Raul de Carvalho, the head of the laboratory of the same hospital, and described a few prophylactic measures for the flu, which included good nourishment and hand disinfection before meals with a few drops of formaldehyde in water or any antiseptic soap.

And this resumes, on a 6,500 entries database and a 60 year time span, the references to hand washing. Hygiene still had a long way to go in 1918.

Also interesting in this research is the persistence, in all epidemics, of the behaviour factor: disease as punishment for excessive and unruly behaviour. This is a religious inheritance which science absorbed and still does not deny, since it has incorporated it into its speech. It manifested again during the AIDS epidemics in the eighties and even during the 2009 flu. Poor hygiene and bad behaviour always seem to be associated with disease and there is always guilt associated. Presently, with the overweight epidemic there is also the bad behaviour factor, and even with cancer. Science knows there are many other factors which are as important to those diseases as social behaviour, such as genetics and the environment, but people are still bombarded with behaviour and guilt, and most of the time, like with cholera or the plague, they don't even know how they got sick…

ARCHAEOLOGY IN THE PORTUGUESE PRESS: A PRELIMINARY APPROACH

Ana Cristina MARTINS[1]
IICT – Instituto de Investigação Científica Tropical, Lisbon, PORTUGAL
ana.martins@iict.pt; ana.c.martins@netcabo.pt

Abstract

During the second half of the 19th century, Portuguese archaeology was scarcely represented in national daily press, compared to the number of articles dealing with news from other countries, informing about archaeological discoveries in Greece, Egypt, and ancient Mesopotamia, etc., as they involved the Old Testament, and the basis of European culture.
However, during the second decade of the 20th century things seemed quite different. That is why we will analyse Portuguese newspapers in order to understand this phenomenon, and the reasons for the identified differences.

"Scientific progress resides mainly in the evolution of its problems."[2]

Initial context

The climate of political instability experienced in Portugal during the 1820s drove young intellectuals into voluntary exile until the liberal regime was finally affirmed. Their preference was for capital cities offering instruments, equipment and an environment essential to academic growth. Thus they chose London and Paris, where they were imbued with influences they would never forget, and from which they attempted to transpose to Portugal the procedures they believed stimulated the progress of nations. This was particularly important in the country because Portugal had drowned in bloodshed for many

[1] Ana Cristina Martins is Assistant Researcher, at the IICT - *Instituto de Investigação Científica Tropical* (Tropical Research Institute) in the *Compromisso com a Ciência* (Commitment to Science) programme, working on projects on the history of science in general and the history of archaeology in particular. She obtained a Doctor's Degree in History, a Master's Degree in Art, Heritage and Restoration and graduated in History – Archaeology, at the University of Lisbon, in whose Archaeological Centre (*Uniarq*) she obtained a post-graduate degree in the history of archaeology, after developing a project on archaeology in Portugal between 1920 and 1969, and worked as main researcher in the "History of Archaeology in Portugal. Theoretical Issues." She has published several articles on the History of the development of archaeological, museological and patrimonial thinking, most of them based on papers presented at national and international meetings. She lectures at the Lusófona University of Humanities and Technology (Lisbon), as Assistant Guest Professor, coordinating the History of Heritage and Science at the CPES - *Centro de Pesquisa e Estudos Sociais* at the Faculty of Social and Human Sciences.

years due to a long series of events starting with the invasion by French troops, a situation worsened by the transfer of the Royal Court to Rio de Janeiro. Other serious events followed, among which was the presence of British forces, the loss of Brazilian gold and the start of a long period of fratricidal conflicts that undermined certainties, beliefs and sentiments, thereby injuring and dividing Portuguese society.

Liberalism was eventually established, and consequently those banished intellectuals returned, having lived in the centres of nineteenth-century culture, nurtured by industrialisation. They encountered a country that faced a very deep crisis, but they also found a land full of hope in a world transformed by new ideological standards. Ideas were discussed, experiences were exchanged and projects were nurtured. However, they returned to a nation afflicted by intrusions, internal discord, anxiety and confusion; a land ravaged by constant pillaging, estranged families, anti-clerical uprisings and the abandonment of properties by absolutist opponents. They had to join forces, inspire willingness and merge desires. It would be the only way to reconstruct buildings and open bridges to the future. There was no shortage of synergy, particularly among those who arrived determined to make the country more European without losing the characteristics that made it a unique Western chess piece strengthened by a vast network of roads and means of transport.

The initial enthusiasm and high spirits soon faded. Portuguese financial problems had exhausted all the government programmes. It is true that roads and streets had been built in order to enhance the new sociability. There were also new laws governing education. However, no fundamental comprehensive reform had been implemented. Of course, there was interest in doing so, and in that regard various projects were devised. People with knowledge in different areas organised meetings, and decisions were made. Priorities were established. However, very little was done due to the difficult state of the country, in which foreign debt had to be settled lest its sovereignty be forever lost. Amid this atmosphere, buzzing with innovations but lacking immediate perspectives, the cultural aspects diminished due to shortage of basic human and material resources for implementing drafted and printed programmes indicating their urgency. Among their authors were intellectuals who understood the problems involving science, technology, arts and literature encountered in foreign countries and who hailed the preservation of monuments to be bequeathed to future mainstays of the liberal agenda. Articles had been published in homeland newspapers since the early 1830s, defending the institutionalisation of this area governed for a long time by other European or, more specifically, French terms. In fact, the *Commission des Monuments Historiques* did some creditable and exemplary work, combining additional knowledge such as drawings and photographs, engineering, architecture, art history and archaeology.

Contrary to what the positivist Europe was doing, Portugal had so far ignored the importance of the past as an anchor point of the present and a cornerstone of the future. This was understandable, since it was not essential to strengthen political frontiers and forge a national identity. Unlike most European territories, the country had no need for the justification of its geographical boundaries other than its own historical development free from the struggle for independence. It comprised a territory, a people and a destination that could be expressed in personal images, uniqueness and identifying symbols. This was complemented by the late arrival of the romantic ideas, the first driving force of nationalistic sentiment in a Europe that had been swept up in the Napoleonic code of ambition.

First tests and disillusions

Despite the government's apparent disinterest and inertia, heritage gained followers, not only among those of an academic and literary bent but also among local and regional powers, which saw it as a means of affirmation among the people they represented, thereby extracting dividends (mainly financial) through cultural tourism. Regardless of these more pragmatic aspects, some people reflected on and prepared national action. This effort was supported by the most informed intellectuals and was marked by the strengthening of historical and artistic studies. It was, however, equally attributable to the public recognition (not simply erudite) of a new scientific discipline, which was essential as a means to scrutinise the most remote ancestors of a particular territory or country. (In fact, archaeology had steadily gained ground since the eighteenth century and rapidly gained scientific acceptance in the following century, when it extracted methods from complementary knowledge likely to achieve its final goal following the analysis of materials, including the reconstitution, although partial, of the history of human communities studied.) However, the official recognition of the existence of prehistoric times opened the door to the subject with which we are now familiar, in the year the historiography of this special subject considers its *annus mirabilis* (1859), being precisely the year in which Darwin's key work, *The Origin of Species,* was published. This recognition was surrounded by considerable controversy from the apparent cataclysm caused to Christianity and belief in biblical texts, being directed toward a different path of knowledge of the past based on evolution, including anatomy. Organising debates in the form of academic meetings, articles, papers, national and international trade fairs, the recognition of prehistoric times warranted the adaptation of field work and office methods that clarified it, thus justifying its reception by universities that transformed it into a central subject. It is essential, since it covered the need to affirm ideas, particularly by those who hoped to stand their intentions on past records, using them to indicate hegemonic and border-claim programmes. As part of the new prehistoric studies, archaeology seeped into the daily lives of the more judicious, establishing new national and regional policies.

A group of intellectuals from the city of Setúbal took on an innovative and monumental project in order to demonstrate their understanding of archaeology's relevance in arousing local spirit and encouraging regional self-esteem in the capital city, Lisbon, which would unfortunately continue to ignore skills accumulated over the centuries across the interior of the country it administered. At the end of the 1840s, it founded the *Sociedade Arqueológica Lusitana* (Lusitanian Archaeological Society) (SAL). Its members, amateurs and liberal professionals hoped to examine Roman ruins, but the project only lasted a few years. The scarcity of financial resources, the apathy of the powers in Lisbon and the distance from the capital obstructed its progress. This scenario was apparently contradicted by the impact of the matter in the local and countrywide press. Despite the illiteracy rate, the press managed to give accounts of current events. Excavation logs were published, articles of opinion were printed, and local people were asked to participate. The SAL increased people's curiosity regarding archaeological matters, albeit in a way that was limited to classical themes.

End-of-century expectations

Archaeological articles should be printed in other publications, but the question was which ones. Portugal was seriously lacking in terms of epistemology. There were projects, of course, but they lacked the structure that would allow them to survive individual commitments, such as those of pioneers in prehistoric research. However, due to the absence of a sustained plan and internal structure, by which they failed to occupy university and school auditoriums, their affirmation, was slower and more oblique. It required support from individual and private institutions.

So, where should they be published? Seeing that there was no magazine on this science, the *Real Associação dos Arquitectos Civis e Arqueólogos Portugueses* (RAACAP) (Royal Association of Portuguese Civil Architects and Archaeologists) (1863) preferred it, since it was the most unprotected science in the country. This started in 1871, following participation in the Paris Universal Exhibition (1867), the inauguration of the *Musée des Antiquitées Nationales* and the third session of the *Congrés International d'Anthropologie et d'Archéologie Préhistorique* (CIAAP) (Bologne, 1871). With an archaeological museum (1864), the RAACAP collected materials representing the most remote past of the region known as Portugal and other places. Additionally, it altered its *Bulletin.* Dedicated almost exclusively to the realm of architecture and fine arts, it began to include archaeological studies and became the first national purveyor. This was how the RAACAP made a difference in this small, specific and young scientific community: by leading a process likely to honour it and recognise it as a paradigm of investigation or, at least, scientific dissemination.

Thanks mainly to the RAACAP, the number of archaeological enthusiasts increased –particularly with respect to prehistoric studies– due to the novelties introduced and the perspectives of discovering the ancestral legacy of each territory. Virtual discernments and discerned realities focused the attention of intellectuals from several cities in the country, causing people to gather together in highlighted nuclei in the belief that archaeology would strengthen local and regional sentiments, thus legitimising unity through diversity. Regardless of these restrictions, Lisbon hosted the ninth edition of the CIAAP during an extremely meaningful year (1880) for its nationalist stimuli. The event brought together famous European names in the sciences of anthropology and archaeology. This gave Portugal a rare opportunity to exhibit work performed in these two fields of knowledge. Great efforts were made. The first archaeological chart of the land (the Algarve) was compiled. Excavation projects were sped up, collections were made and a whole social programme was created, which was remembered for many years after the work was officially concluded. The importance of this international meeting was recognised by learned society of the time, and daily records of the sessions, officially opened by royalty, were published in the press.

This increased the hope that institutional support would be received on behalf of archaeology's introduction into the university sphere. It was certain that the presence of so many names recognised abroad would persuade the national authorities in this regard. However, despite the undeniable success of the encounter, the government remained distant. Contrary to expectations, unmatched efforts to publicise the event were basically thwarted, and of course the press alone could not successfully establish archaeological science among the population. This is to say that the country was not structurally prepared to receive it. Logically, the press did not have the power to influence decision-making, and this fact was also evident in weak scientific intellectuality.

Contrary to what was expected by the Portuguese organisers of the ninth CIAAP, archaeology was not officially recognised; instead, it remained outside the spheres of university life and academia. Consequently, it continued to be a subject of study among erudite private associations, which endeavoured to keep pace with collections and museums, some of which were municipal. It was also on a regional basis that enthusiasts of this science found the considerable support they needed; a manner of assistance that was consolidated from large-scale landowners, shop owners and literate industrialists who, concerned with cultural and scientific issues and strengthened by their personal prestige, could acknowledge their role in those areas.

Despite the sense of dissatisfaction, the attention of newspaper readers grew in regard to the new area. This was how the first seeds were sown. However, there was still a long way to go. Nevertheless, unexpected novelties arose in benefit to archaeology. The preservation of archaeological sites was discussed at the ninth CIAAP. The matter was also discussed in countrywide forums, where pages of publications were written without obviously reflecting on specific measures. In response to protests that had been voiced since the 1830s in favour of safeguarding heritage, the government asked the RAACAP to list the ancient structures it considered worthy of classification as "national monuments." This was a step forward. Furthermore, it honoured the RAACAP by recognising its capacity to fulfil this mission. The extensive network of corresponding members established over the years allowed it to provide a quick, assertive response to the government's request. Early in 1881 it presented the report, distributing structures into six general categories, the last of which was archaeology. This was the first time Portugal included archaeology as a topic of heritage. Accordingly, it justified the establishment of the National Monument Commission (NMC), a body that would unfortunately do very little due to insufficient staff and funding.

A novel aspect of the document was the fact that the sixth section almost exclusively comprised prehistoric specimens, mainly representing the megalithic culture. This should not come as a surprise, since it is still a key topic in European archaeological circles, particularly given the political importance accorded by local, regional and national ambitions. Portugal, however, had no autonomist or regionalist problems, nor were there any autonomist aspirations; but researchers could not ignore the most recurrent matters discussed, and thus they established specific work groups. On the contrary, they felt that they should include them in order to avoid isolation and the loss of precious relationships established in unison with other scientific assemblies. By covering them, methods (but not theories) were copied. They emphasized the so-called unique characteristics of artefacts encountered in dolmens, such as engraved schist plates. This is found to have been illustrated in national newspaper banners and headlines. Although it was a topic for newspapers, privately launched specialist publications appearing at the end of the nineteenth century explored it in greater detail.

Concurrently, the Portuguese Ethnographic Museum was founded (1893) through personal effort and political and social capital, the latter of which was frequently evident in general press. This occurred mainly from 1906, the year in which it opened its doors to the public, making it the first institution of its kind to house archaeological and ethnographic materials presumably representing "Portuguese mankind" and associating it with land that had been occupied since the Neolithic era. Thus the end of the nineteenth century opened a new chapter in Portuguese archaeology. The foundation gained form with legal documents from the end of the constitutional monarchy, protecting archaeological sites on public land and making more difficult the sale of artefacts abroad. Meanwhile, the opening of new museums in various inland cities of Portugal was announced, many of which contained archaeological collections. Some of them arose from excavations conducted within their administrative borders, which multiplied local and regional societies whose work was mainly dedicated to such effort. This scenario, however, did not last long enough to make archaeology a solid science. Many protagonists died or passed away. The once rapidly growing impetus, traces, projects and basic connections for their pursuit disappeared and were only recovered years later by local and regional politicians.

Republican achievements

The instauration of the Republican regime (1910) renewed expectations. It was what had been indicated by the academic project that emerged near the end of the preceding century, bearing in mind academic training in the form of printed speeches, debates and intellectual opinions from the first ranks of the new regime. It appeared that the Republic would protect heritage, science and technology as the buttresses of its philosophy. Specific laws were published, covering national museums on an agenda marked by positivism and conviction in regionalist politics. A lot was done, but there was still much more to do. The country was not politically stable. Cities did not have enough specialists in architecture, art history and archaeology to satisfy the programme that, not long before, had been outlined by the Art and Archaeology Councils. Nevertheless, regionalisation achieved the desired goals. Among them was the creation of museums in different places, many containing archaeological collections that encouraged the publication of journalistic articles. However, only some actually were. Generally, it was as if the newspapers –particularly the daily ones– ignored archaeology or put it into second place during the first years of the Republic. This was not the case with the local and regional papers, obviously due to the curiosity and interest they satisfied.

It is important to remember the profound instability experienced between 1910 and 1928, when journalists focused on political, economic and social aspects. Even so, archaeological digs, temporary exhibitions on the subject and speeches by the director of the PEM, José Leite de Vasconcelos (1858-1941) were reported, thereby strengthening his position within the limited framework of specialists in such a specific topic. The truth is that he became an icon of our archaeology and ethnography, and articles were often published concerning the work being performed, mainly when he travelled throughout the country in search of objects for the museum for which he was responsible. This also occurred when he travelled to distant locations in order to participate in international scientific congresses, meet famous representatives of the subjects he had nurtured. Therefore, it is imperative to ask whether the daily press was fascinated by his activity or his personality. What aspects attracted their attention and what attracted readers? Regardless of the answer, a procedure applicable to other people was copied. For the first time, the press was repeatedly following the path of a leading archaeologist. Once in the press, Leite started to exist for society, strengthening and supporting the institution he managed. As a whole, this news benefited science by spreading it, however indirectly it might have done so.

The *Estado Novo* and its ideas

It seems that only with the totalitarian *Estado Novo* regime articles on archaeology started to appear in abundance. Why is this so? Perhaps it is because the subject was institutionalised right after its inclusion in university programmes, at least in Lisbon. Moreover, the transition from the nineteenth century to the twentieth century witnessed the launches of magazines often containing articles on archaeology, some of which were accompanied by pictures and photographs. By elucidating underlying ideas, a significant part of these publications were called *Portuguese Land*, *Lusitanian Journal* and *Lusitanians;* titles that strongly linked Portugal to ancient Lusitania, whose warriors fought bravely against legions from Ancient Rome. It was an understandable connection, in light of exogenous ambitions regarding Portuguese overseas territories. It was time to recover national pride and strengthen identity. Therefore, the "New State" included archaeology on its agenda, just as it did with respect to most scientific fields. Even though the country did not need it to legitimise frontiers, increasingly articles on archaeology appeared in the newspapers. This was probably due to the growing numbers of wealthy individuals, having participated in Portuguese university training, focused on it. It was also due to the proliferation of erudite societies supported by the Portuguese Archaeology Association.

This warranted the need to organise and supervise archaeology. The second director of the PEM, Manual Heleno (1898-1970), was essential for internal archaeology, being on a par with powerful names in Oporto, Coimbra and Lisbon. Contrary to the nineteenth-century historiographical tendency to settle in the Portugal of the Middle Ages, M. Heleno based it on the Neolithic era, or more specifically the megalithic period. Thus he dedicated most of his life to demonstrating it. This was such an important issue for the New State programme that it became a journalistic *pièce de resistance*, as his digs, their results and interviews with the person responsible for them often appeared in the papers. It seemed that archaeology had finally found its path among the populace, or perhaps they discovered archaeology. To culminate the long process of the institutionalisation of this science in the country, there appeared many more studies of its main followers, printed in Portugal's leading newspapers and magazines. It was as if archaeology had been accepted by society as a whole, especially the literate, occupying universities and schools and contributing to local finance through tourism. This acknowledgment was well established in the First National Archaeology Congress (1958), with the presence of foreign leaders.

Reflections and suggestions for study

The daily press started to become more interested in archaeology when it became politically and economically important as a pillar of so-called cultural tourism. This is only one side of the issue, however. It is important to scrutinise newspapers and magazines, and to analyse the quantitative and qualitative differences of the content published in the national, regional and local press. Topics should be identified and the importance of archaeology understood for the sake of clarifying identities and the economic progress of each territory, doing so through geographical comparison. Moreover, it is important to compare the number of articles on archaeology with those pertaining to other sciences, so as to obtain a closer view of its true political and social role. This assessment should contemplate the types of articles published, but more specifically it should consider whether they were scientifically credible or mere descriptions of archaeological episodes. Various other aspects should also be considered, such as the question of which pages of the newspapers and magazines the articles were published. Was it the first page? If so, which types of articles were printed? Was there a difference between the quantity, quality and location of articles in the national, regional and local press outlets? Who were their authors? Were they journalists with scientific knowledge? Was their content reviewed by specialists? Were archaeologists questioned by journalists in regard to specific information? Did periodicals manage to certify any archaeological praxis?

Clearly, there are more questions than answers, at least for now.

Abstract

In this paper we present the results of a comparative study of the return of Halley's Comet in 1910, as presented in the Greek and the Portuguese generalist press. Our work is based on a common bottom-up approach offering a complete survey of all relevant news published in two different newspapers in each country: the Greek newspapers Embros *(Athens, 1896) and* Skrip *(Athens, 1893), selected for their wide circulation because at the period under examination newspapers had no clear political orientation, and the Portuguese newspapers* Diário de Notícias *(Lisbon, 1865) and* Diário dos Açores *(Azores, 1870), chosen on the basis of their broad ideological scope and different geographical locations. We offer some conclusions, which explore the contrasts and similarities of how the return of Halley's Comet in 1910 was reported in both countries.*

Introduction. Comparing public perceptions of science in the Greek and Portuguese press

Despite the renewed interest in the role of mass media in communicating science and technology to non-specialized audiences, historians of science have paid scant attention to the daily press as an object of research *per se*. Although the fields of media studies and cultural history have long recognized that newspapers are crucial in the making of public opinion, in the history of science we are just beginning to establish the nature of newspaper coverage and to account for its importance.

Recent studies have shown that the daily press can be seen as a particularly suggestive source for the public images of science and technology and the public perception of their role in society. Moreover, the extent to which science and technology are topics that permeate the entire newspaper and are not limited to specific columns dealing with "science popularization", is indicative of the important role science and technology played in the formation of modern societies. To what extent can newspapers be seen as privileged media for the examination of the cultural meanings of science and technology in different local settings? How do the main political, social and cultural features of a period influence the public discourse about science and technology, and how in turn do discussions about science and technology in the public sphere transform the ideological, social and cultural formations of each historical period?

In this paper we present the results of a comparative study of the return of Halley's Comet in 1910, as presented in the Greek and the Portuguese generalist press. Our work is based on a common bottom-up approach offering a complete survey of all news published in two different newspapers in each country: the Greek newspapers *Embros* (Athens, 1896) and *Skrip* (Athens, 1893), selected for their wide circulation since at the period under examination newspapers had no clear political orientation, and the Portuguese newspapers *Diário de Notícias* (Lisbon, 1865) and *Diário dos Açores* (Azores, 1870), chosen on the basis of their broad ideological scope and different geographical locations. While the one was published in the capital city, had a very wide circulation and no clear political orientation, the other was issued in one of the Azorean islands located in the Atlantic and was associated with the monarchic intelligentsia linked to the Partido Progressista.

Besides methodological commonalities, that is, besides having based our research on the complete survey of all news appearing in successive days in all newspapers, we initially decided to focus on the first decade of the 20th century because both countries were undergoing turbulent political times, and similar journalistic trends.

In Greece, the first decade of the 20th century is indicative of a broader historical period, characterised by a programme of modernisation of the country as well as an expansive national policy. The latter was, nevertheless, severely compromised after the defeat of Greece in the Greek-Ottoman war of 1897, the imposition of the International Financial Control in 1898, and the intensification of Balkan nationalisms. The political instability of the period culminated with a military revolt in 1909, which was also supported by large parts of the population and trade unions, all asking for the military, social and political reform of the country. The military revolt brought, in 1910, into power the Cretan politician Eleftherios Venizelos, who presided over a vigorous program of constitutional, military and social reform and represented the hegemonic national ideology until the defeat of Greece in the Greek-Turkish war in 1922.

Portugal, on the other hand, lived the difficult aftermath of the British Ultimatum and the Berlin Conference (1895) at a national and international level. The international credibility of Portugal was severely damaged to such an extent that colonial matters played a part in the overthrow of the monarchical by a republican regime in 1910, precisely the year of Halley's passage. Therefore, the implantation of the Republic on October 5 brought hope in a new society built on democratic, socialist-oriented, anti-clerical, nationalistic and colonialist values. While some of the former characteristics are easily understood as a reaction to monarchical values, nationalism and colonialism were a response to the outcome of the Berlin Conference and the Portuguese reactions to secure its African colonies. Ideologically, they had the support of many intellectuals who praised the gospel of positivism and endorsed scientism, mostly as an initial reaction to a society formerly dominated by religion, and subsequently as a more or less articulated philosophical project.

Regarding journalistic trends, both countries were undergoing similar processes, not only in terms of the printing technologies used, which accounted for the broader and cheaper dissemination of newspapers, but also in relation to new journalistic genres, replacing opinion articles for more "neutral" news, which left to the readers the task of forming their own opinion. Finally, both countries had a high illiteracy rate, around 50% for Greece and 80% for Portugal. However, this very characteristic makes newspapers, through multiple and oral readings at various public places, a privileged source to survey the public opinion on science and technology matters.

As in both Greece and Portugal "locality" often guided the selection of news and, furthermore, shaped their presentation, we selected the return of Halley's Comet on May 1910 as a particularly suitable case study on which to base this comparative exercise. On May 18, 1910 Halley's Comet was due to make its periodic passage near the Earth. Spectroscopic analysis had shown that the tail of the comet consisted of poisonous gases and extensive news coverage in the daily press spread panic around the world, reporting that the Earth would travel through its tail. The number of news on the comet was roughly the same in both the Greek and Portuguese newspapers surveyed (around 90) and in both cases most of them appeared on the month of May.

The return of Halley's Comet as seen through the Greek press

A year before the return of Halley's Comet, the journalists of the Athenian newspaper *Embros* had predicted that its passage would turn into a major journalistic event. Indeed, *Skrip* and *Embros* covered the event in a similar way with more than 40 articles each. Brief articles in the middle pages announced the latest news concerning the orbit of the comet from various observatories around the world. Longer ones traced the previous appearances of the comet and linked them to great, mostly destructive, historical events. Almost the majority of the translated articles came from French newspapers, and many of them were extracts of texts written by the acclaimed populariser and amateur astronomer Camille Flammarion. These articles, sometimes accompanied with illustrations, aimed at giving the public a general idea about the nature of comets and their orbits and informed about possible threats to the world. On various occasions both newspapers published interviews of Dimitrios Aiginitis, Professor of Astronomy and Meteorology at the University of Athens and Director of the National Observatory, and other members of the Greek scientific community. They also reported in detail public events, such as public lectures on the comet or even theatrical plays inspired by the comet.

Halley's Comet was an exceptional astronomical event with multiple repercussions in people's daily life. Newspapers seem to have been the most important medium through which information concerning the comet was made known to a wide public. Through newspapers' diverse types of articles about the comet, the Greek public was familiarised with astronomical terms and notions, instruments such as telescopes and spectroscopes, as well as sites of astronomical research. Popular science articles on Halley's Comet were avidly read, and then discussed in coffee shops, taverns or other public spaces. As the chronicle-writer of *Embros* observed, the comet left behind a great number of "astronomers" who continued to discuss their theories over a cup of coffee. People gained also first-hand experience with at least one aspect of astronomical practice –observation– during the nights when they stayed awake in order to observe the strange visitor of the sky over their heads.

Despite astronomers' accurate prediction of the return of Halley's Comet on May 18, contradicting information concerning possible threats to the planet put at stake and reinforced, at the same time, the trust in experts. Journalists used scientific loanwords in order to enhance the authority of their writings, but also to render their articles spectacular and attractive. Although most astronomers were reassuring concerning the possible threats posed, the reporting of the poisonous constitution of the comet's tail as well as its unconceivable length (ranging between 23 and 25 million kilometres) were sensational enough to create an ambiance of anxiety. Most chronicle-writers found the effect of the news on the public rather amusing. They took the opportunity to walk among the excited Athenians, who camped on the hills of the capital so as to observe the comet, and reported on a daily basis the most entertaining dialogues. Although critical of "end of the world" scenarios, journalists insisted on writing about them in order to provoke sensation among their readers. This choice was dictated by, and at the same time fed, the main topic of discussions taking place in public spaces.

May 19, when everybody woke up safe and sound, marked the beginning of a new series of articles that criticised not only the credulity of the lay public, but also the unreliability of the astronomers. Journalists blamed foreign astronomers for the dissemination of false information that created panic and in some cases led people abroad to take their own lives. They also implied that most Athenians experienced the passage of the comet in a climate of euphoria, because of their own calm stance when reporting the news. Although journalists were harsh in their criticism of foreign astronomers, when it came to the local community, they showed respect and reproduced uncritically the reports of the National Observatory. At the same time, both newspapers served as a forum for local scientists, who portrayed their science as a "positive" one, self-fashioned themselves as experts and enhanced their role in Greek society. Through these interventions, the newspapers gained also the credit of being a legitimate vehicle of scientific knowledge.

The return of Halley's Comet as seen through the Portuguese press

The two Portuguese newspapers selected covered extensively the passage of Halley's Comet, but there are interesting differences between the two. The amount of news by the capital newspaper (67) is roughly the triple of the news by the islander newspaper (25). In both newspapers news on the comet was given a prominent place and were evenly distributed throughout the newspaper (first five to seven pages out of ten, in the capital city newspaper and first two pages out of four, in the islander newspaper). News on the comet were also unevenly distributed around the year, with a peak in May, when the comet was supposed to be closest to Earth (18-21 May), and disappearing abruptly after its passage. Furthermore, while in the Portuguese Azorean newspaper news were not located in special science sections and were never illustrated, probably due to printing limitations, in the capital city newspaper they were at times located in a science section called "Scientific Chronicles," or in special sections not necessarily related to science such as "Chronicles from Porto," and were often accompanied by figures.

In both newspapers, a substantial fraction of news centred on giving readers practical information on the comet, including the characteristics of its trajectory, its constitution (nucleus, wig and tail), its effects on Earth (mechanical, calorific and chemical), and its history, as well as visibility conditions or varied information stemming from different observatories across Europe. Like in Greek newspapers, they were often based on the expert opinion of foreign popularisers of astronomy such as Flammarion or his friend in Portugal, Théophile Moreux. Contrary to Greek journalists, Portuguese journalists did not place so much emphasis on the possible threats of Halley's passage on humanity. References to the possible dangerous, or even deadly, effects of cyanogen and other gases were counteracted by articles by some Portuguese scientists who explained that spectroscopy enabled to identify the composition of the comet's tail, but could not calculate its density, so that there was no evidence that gases existed in such quantity as to become a dangerous threat to life on Earth.

The importance conveyed by national/local astronomers or scientists is also a crucial characteristic of both Portuguese newspapers: the islander newspaper gave prominence to local/Azorean scientists, and the capital newspaper assumed strongly its role as a national newspaper and included more encompassing news. In fact, the Azorean newspaper reproduced, in successive articles, a conference about the comet, which was delivered by the well-known amateur scientist Colonel Afonso Chaves. More than its timeliness, the comet's return was addressed due to the association of astronomical events to weather and earthquake prediction, a problem of greater relevance to the islands, and especially to their scientific elite. Chaves used the newspaper as a communication channel to win the local elites for the agenda of the scientific community, whose aim was to render Azores an active node in an international network of meteorological and seismological observatories. The newspaper also drew attention to another Azorean astronomer, lieutenant Melo e Simas, who delivered a speech on the comet in the context of the newly founded Academy of Sciences of Portugal.

Contrary to the Azorean newspaper, which was more focused on particular kinds of news and topics, in Lisbon, newspapers covered different typologies of news: astronomical information on the comet both from foreign or local scientists, science popularization articles, description of various reactions of the population in Portugal and abroad, news issued by a recent scientific society which emerged in association with the blossoming republican movement, questions asked by readers or observations sent by them, announcements of different social events related to the comet, advertisements on national or foreign books about the comet, or advertisements on a special anti-comet powder supposedly validated by the scientific community; and, finally, literary and satirical texts sent by locals to the newspaper using the comet as pretext to enrol in various social and political criticisms.

Portuguese scientists appropriated the comet's passage to enrol in popularization of science. The importance of popularization as a means to educate the working class and the population at large reflected the endorsement by committed intellectuals' of positivism and scientism as antidotes to a society so far dominated by religion and the Catholic Church. Initially a reaction to a retrograde society, this trend gave way to a more or less articulated philosophical project, which materialized, for instance, in the creation of the Academy of Sciences of Portugal, in 1907. Spokespersons of the Academy used science to fight against uneducated people's fears and superstitious beliefs.

If many scientists used the capital newspaper as an outlet for their popularization of science activities, some astronomers used it also as a means to push forward their scientific agendas, and specifically to gain advocates for astrophysics. Costa Lobo, for instance, made a plea for the importance of this emerging sub-discipline, explained its association with new techniques such as spectroscopy and photography and argued for the need to buy appropriate instruments. Besides talks by well-known scientists, the reader was also informed about talks taking place in workers' or socialist associations by less well-known speakers (Inocêncio Camacho), clearly partaking of the spirit of the time, that is, the movements of "education for all".

One of the most revealing traits of the Portuguese newspapers is the prominent role played by the local population in informing journalists of the activities taking place in their localities concerning the comet, and the reactions of the population that ranged from fear, terror and suicidal attempts to celebrations and the organization of various social events. Often readers offered satirical and literary descriptions of real or imagined comet-related situations, such as a politically and socially oriented critical text of a telegram supposedly sent by the Comet itself while passing above Portugal. The active role of the population was such that readers made suggestions or even criticized journalists for publishing sensationalist news in order to increase their audience instead of enlightening the population by publishing digests of scientific information. The contrasting role of journalists and journalism as seen by readers was also paralleled by the dual role played by priests and the Church. Priests were portrayed in two opposite ways: as those who usually reinforced public fear about the "end of the world" as signalled by the comet's passage, or, exceptionally, as people who could use their sermons in a constructive way by enlightening their audience as to the effects of the comet.

Despite the wealth and variety of news issued by Lisbon newspaper, one should realize that this did not subscribe to any specific scientific agenda of popularization as the Azorean newspaper did. This is clear when one contrasts percentages of news on the comet relative to all news on science, technology and medicine in both newspapers (27.6% for *Diário de Notícias* compared to 7% for the Azorean newspaper), meaning that *Diário de Notícias* simply registered scientific events as they emerged, depicted reactions to them, and gave a place to national scientists who used it as an outlet for their popularization agendas. On the contrary, in the Azorean newspaper the agendas of the local scientific elite were, almost permanently, at the core of the newspaper's contents.

Comparative approach at stake: What did we gain? What do historians gain?

The importance of "locality" in shaping scientific news is evident from the dissimilarities found between Greek and Portuguese newspapers, as well as between Portuguese newspapers. Certainly the choice of two Greek newspapers from Athens, and two Portuguese newspapers from two different cities, one in Portugal mainland and the other in one of its islands, is at the core of the asymmetric results obtained when comparing Greek and Portuguese newspapers. Furthermore, in contrast to the Lisbon newspaper, in the Azorean paper, news on science appeared regularly in accordance with the interests of local intellectuals and scientists who did not need the occurrence of spectacular natural events to have their voices heard.

Similarities among all newspapers are probably tied to international trends. In fact, newspapers in both Greece and Portugal extracted news from the foreign press (especially French) and published opinions of popularisers such as Flammarion, whose presences was regular whenever astronomical phenomena were involved. However, news from abroad was appropriated in contrasting ways. The belief that the poisonous composition of the comet's tail was a real threat to life on Earth was more intense in Greek newspapers than in the Portuguese. The respective assessment of some foreign astronomers' claims from both Greek and Portuguese journalists differed. Greeks but not Portuguese journalists blamed the foreign astronomers for the panic created, while both Greek and Portuguese considered local astronomers a very reliable source.

In both countries, despite journalists' references to possible dangers from the comet's passage, the local scientific community downplayed such a danger and provided reassuring information. All newspapers gave astronomers' ideas a prominent place. However, the impact of the scientific community seems to have been much stronger in the Portuguese than in the Greek case. This difference has probably to do with the strong agendas of Portuguese scientists, who took the opportunity to use the daily press as means of their engagement in the popularization of science and their fight against obscurantism. It is, therefore, clear that the strong popularization of science agenda which characterized the new Republic had its roots at least in the final years of the Monarchy. In the case of Greece, the local scientific community engaged in science popularisation from the 1870s, mostly through the publication of articles in general periodicals and through public lectures. At the turn of the century, they started contributing to more specialised journals and appeared on the daily press mainly when they were interviewed by journalists. With the exception of engineers, who were often involved in debates concerning public works, we rarely find cases of local scientists contributing systematically to the daily Greek press.

The participation of the public, specifically with letters to the Lisbon newspaper, has no parallel in Greece. In the Athenian newspapers, journalists were the ones who reported the reaction of the public to the news, and transcribed dialogues between themselves and the public so as to create a sense of immediacy. However, it is impossible to know whether such descriptions were invented so as to serve the journalists' purposes, or whether they actually took place. This difference is quite unexpected having in mind the greater illiteracy of the Portuguese population. But on a second reading, one should recall that despite oral and multiple readings in various public places, these contributing readers were the local elite of each city, town or village. A newspaper such as *Diário de Notícias* counted on the reports of informants from various localities all over the country, who were often their primary school teachers, lawyers or solicitors, doctors or priests.

Coming back to the questions posed at the beginning of this paper, we conclude that despite and at the same time because of differences in contents and approaches, newspapers in Greece and Portugal are privileged sources for the examination of the cultural meanings of science in different local settings. The main political, social and cultural features of the first decade of the 20th century in Greece and the republican movement in Portugal, with its emphasis on positivism and scientism shaped the public discourse about science in characteristic ways. How, in turn, discussions about science in the public sphere, and specifically in the daily press, transformed the ideological, social and cultural formations of each historical period is harder to ascertain and are still to be clarified.

SECRETIVE GEOLOGIES: DANISH AND AMERICAN AGENDAS FOR THE GEOLOGICAL INVESTIGATION OF GREENLAND, 1946-1960

Christopher Jacob RIES
Department of Science Studies, Aarhus Universitet, DENMARK
cjries@ivs.au.dk; http://pure.au.dk/portal/en/khn@ivs.au.dk

Abstract

Between 1946 and 1958 a peculiar division of labour existed in the geological investigation of Greenland. During this period, the ice-free lands of Greenland was generally explored in four largely independent institutional settings –one of them American and three of them Danish– each investigating their own region of the island according to their own agenda, and each having their own reasons for maintaining varying degrees of isolation from the others. Preliminary in nature, this paper attempts to outline some Danish and American institutional settings for geological investigations in Greenland, as well as some of the scientific and political agendas that they followed.

A geology of Greenland in four parts (+ one)

By the end of WW II the Arctic had achieved superior strategic importance to the nations on the Northern Hemisphere. Consequently, the Danish colony of Greenland became the scene of extensive geological investigations conducted under the auspices of the US military, as geologists of the Military Geology Branch of the US Geological Survey investigated large portions of the ice-free areas of northern Greenland to identify possible sites for air bases, natural landing strips and other military activities (Davies 1972; DeGoes and Neal 1998; Krinsley 1994, 1998; Weidick 1999).

In contrast, Danish field activities were almost entirely concentrated south of 78°N. On the east coast, the Danish geologist Lauge Koch, resumed the large-scale investigations conducted by him in the 1930s, directed on behalf of the Danish Greenland Administration with almost no participation from Danish geologists. Paid by fees from the Greenland Administration negotiated year by year supplemented with contributions from private investors, Koch relied heavily on his ability to muster sufficient popular and political interest in his activities to secure additional state support and private funds for his activities. Thus, economic geology and practical mineralogical investigations became important elements in Koch's investigations (Ries 2003, 2007).

The Danish Greenland Geological Survey (GGU), established in 1947 for that exact purpose, investigated the west coast. As a regular state institution financed routinely via the state budget closely aligned with the Dept. of Geology at Copenhagen University, GGU focused on general geological surveying and mapping, while serving as a training ground for a new generation of Danish geologists emanating from Copenhagen University in the decades following WW II (Ellitsgaard-Rasmussen 1996).

By comparison, Danish involvement in the geological investigation of Northern Greenland was limited. From 1954 onwards the Danish Liaison Officer at Thule Airbase was assisted by a Danish Scientific Advisor recruited on a yearly basis –often a young geologist– to assist in the supervision of US scientific activities in the region. However, given the rate of exchange of persons in this position, and the intensity, extent and variety of US activities within a range of scientific disciplines, this task did not leave much time for scientific investigations.

The most constant Danish individual presence in Northern Greenland in this period was the archaeologist Count Eigil Knuth, who stayed and conducted a series of smaller Danish expeditions in and around Peary Land between 1947 and 1996. In the period dealt with in this paper, three geology students of Copenhagen University each carried out one season of geological investigations on Knuth's Danish Peary Land Expedition by 1947-50. In 1952 and 1953 small parties –two or three men– of Swiss and English geologists from Koch's East Greenland expeditions carried out geological work with summer parties in Peary Land. But apart from these minor exceptions, Danish activities were concentrated on the east and west coasts of Greenland, leaving the geological exploration of North Greenland to the Americans.

Greenland Geology between Danish Sovereignty and US Military Interests

Until the early 1960s, when missiles took over the role as the primary strategic deterrent for Soviet aggression, the ability to apply nuclear weapons between continents was determined by the availability flight routes between the Western Hemisphere and the Soviet Union. In 1946, a report from the US Joint War Committee gave the following assessment of the North Greenland coast as a possible steppingstone for transatlantic aircraft activity:

> *"Within the next ten years the strategic importance will increase progressively. When certain technical difficulties of operation from Arctic bases can be overcome and the problem of logistic support be solved, the northern part of Greenland could provide a base area for the projection of strategic air operations. However, a more positive determination of the extent to which this area could be utilized will be obtained when the data collected by recent expeditions has been analyzed."* (DUPI 1997)

During WW II, the USA had operated a small weather station at Thule, Greenland's northwest coast. In 1946, the army built a landing strip at Thule as an operational base for photographic mapping missions, and from 1946 onwards the US Air Force carried out systematic photogrammetric mapping over all of North Greenland to investigate regions and locations fit for additional weather stations, military bases, auxiliary airstrips and trafficability (Laursen, 1972, p. 150-151).

As US air operations increased in North Greenland along with demands for more complete weather information, it became apparent that there was an urgent need for a weather station and an emergency airstrip on the northeast Greenland coast. In 1948 and 1949 the US Geological Survey in cooperation with the Arctic Section of the US Weather Bureau, began air surveys of the north-easternmost part of Greenland in search of a site for a weather station in the region. When, at a meeting in Copenhagen in June 1950, the USA formally suggested the establishment of a joint Danish-American weather station, it caused some concern among Danish government officials. The then Danish Head of the Greenland Department of the Danish Ministry of State, Eske Brun, in 1957 summarized the negotiations and their outcome to Danish Minister of Greenland Johannes Kjærbøll: *"Station Nord was originally established because the Americans wanted a weather-station in that particular region, and we wanted to keep them out of there. We have succeeded in keeping the station entirely on Danish hands …"* (DUPI 1997, 200).

On April 27th 1951, an agreement was signed between the USA and Denmark concerning the common defence of Greenland, allowing the USA to conduct military and scientific activities inside their base areas without Danish interference, while demanding all planned activities outside the bases to be presented to and approved by the Danish state. The agreement also gave the USA the use of a greatly expanded area around Thule, where major construction works from 1951 through 1953 resulted in a 3 km long asphalt-surfaced runway with operational apron, hangars, taxiways and considerable supporting base facilities.

Preparations for the establishment of Station Nord commenced in the autumn of 1951 when, even before the exact location was decided, the Americans promised to provide technical assistance and transport of necessary personnel and material from Thule. The Station Nord site was selected in April 1952, construction began in the summer of 1953, and the 2.5 km gravel runway at Nord became operational in 1954. The station however formally remained under Danish authority, and US requests for Danish permission to establish an 'outlying base' under US control on the East Coast opposite the Thule Base recurred several times. The permission was never given, and in 1953 the USA formally relinquished all plans to establish their own base in North East Greenland. Station Nord remained under Danish control, allowing the US Air Force to use the airfield for emergency landings only. Such landings appear to have occurred only three times: in January 1957, October 1957 and February 1958 (DUPI 1997).

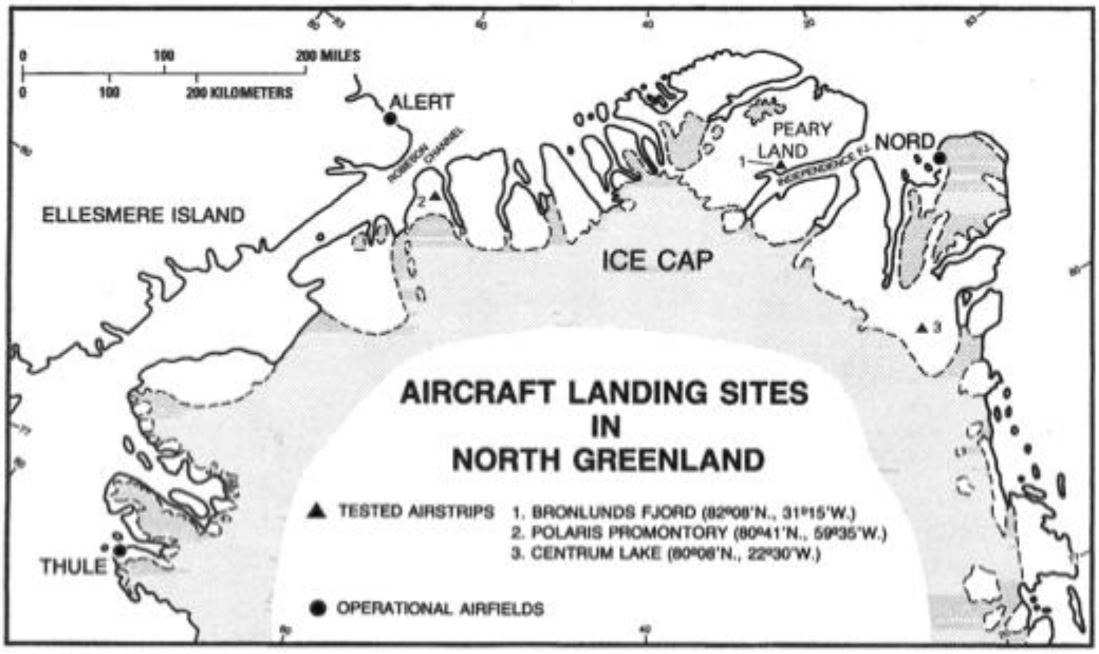

Fig. 1: Aircraft landing sites in North Greenland (Krinsley 1998).

US military geology and terrain intelligence in Northern Greenland

Although attempts to establish a second US base in North East Greenland had been formally renounced, American military activities in the region persisted. However, transformation of Greenland from Arctic wasteland into a bridgehead in American Cold War military strategy required the development of new forms of extensive and detailed scientific investigation of the terrain and environmental characteristics of the region.

It was exactly this understanding that informed the views of the Office of Naval Research under the Arctic Research Advisory Committee of the Arctic Institute of North America, as it charted out the military strategic potential of an expansive US engagement in Greenland at a meeting in the Commission on Merchant Marine and Fisheries of the House of Representatives in January 1957:

> *"Science will permit our use of Greenland as an Arctic sword and shield –a mighty bastion of deterrent power essential to the NATO concept* […] *An absolute prerequisite to our effective use of the high Arctic is harnessing of its environment. The Arctic's true military potential can only be transformed to the dynamic by means of studies specifically oriented to the problem.* […] *However, more knowledge is required to permit military man to work with the cold rather than against it, and to do so in a practical and economic manner. The Arctic is friendly only to those who comply with its implacable laws."* (Arctic Institute of North America 1958)

In general terms, the development of nuclear weapons for tactical use after WW II was followed by a concept of warfare based on small, mobile combat units equipped with helicopters, aircraft with short take-off and landing capability, and low ground-pressure vehicles, which could move across country to supply rapidly shifting forces. This in turn affected the kinds of geographical knowledge required for the strategic planning of military operations.

Analysis of landforms as they offered shelter from nuclear blast, safe routes for helicopters, tanks and supply vehicles, sites for rapid airfield construction and paratrooper landings and the suitability of soil for hasty excavation of shelters became of prime importance for the conduction of military operations (Whitmore 1960).

Guided by the military need for terrain analysis for strategic and engineering purposes then, the US scientific agenda for geological investigations of North Greenland focused on studies of short-term dynamic processes of geological disintegration, erosion, transportation and deposition of rock material with a marked interest in surface geology. Shore processes were studied in order to appreciate the effect of frost and thaw processes and sea ice shove, and the stability or lack of stability of beach shapes, to assess the possibility of the construction of docks. Likewise, the formation and preservation of permafrost and its effects on various types of terrain were studied relative to the establishment of foundations, water supply, waste disposal and transportation.

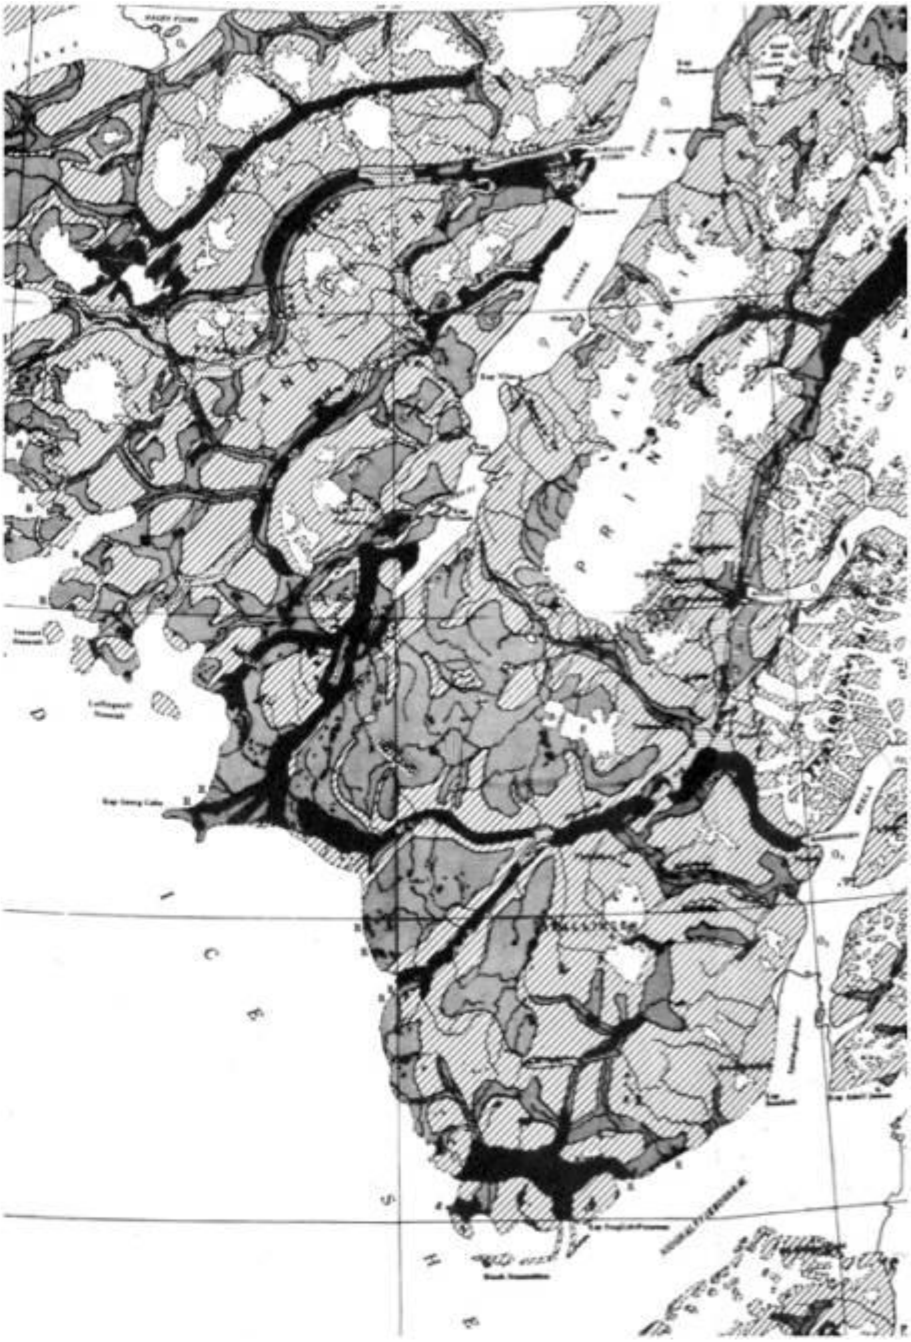

Fig. 2: Terrain Map of North Greenland with reference to the operation of air-cushion vehicles (excerpt) (Davies 1972).

These were the concerns that shaped the scientific tasks of the personnel of the Military Geology Branch of the US Geological Survey, which partook in a series of investigations during the 1950s and early 1960s under contract with the US Air Force and US Army, in order to find locations fit for establishing auxiliary landing sites and other logistic centres along the North Greenland coast between Thule and Station Nord. Candidate sites were selected by analysis of aerial photography, with subsequent detailed on-site studies. Where possible, those sites with acceptable parameters were subjected to test landings by heavy C124 and C130 transport aircrafts (Krinsley 1998).

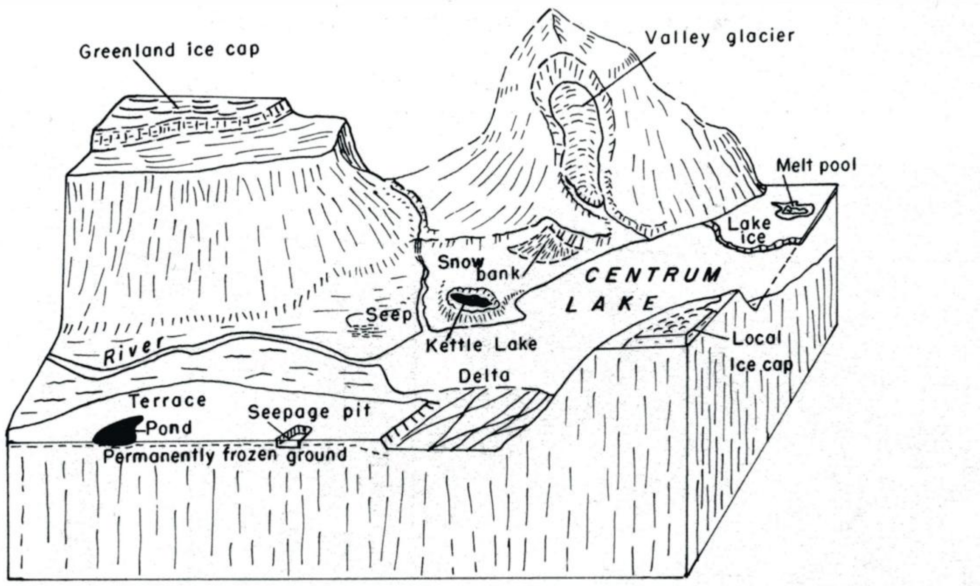

Figure 55. Possible sources of water at Centrum Sø.

Fig. 3: Possible sources of water at Centrum Sø (Needleman 1962).

Similarly, terrain analyses were made as a basis for site selection for transportation routes, facility sites, foundation conditions and camouflage possibilities. This would involve the mapping of glacial features, terraces, flood plains, beaches, including raised beaches, and other land forms. Engineering geology studies explored for the use not only of surface materials, but also of bedrocks and caves as underground facilities, of particular interest militarily, held special possibilities for protection both from the enemy and the weather, for economic operation and maintenance, and for good foundations (Davies 1959; Davies, Krinsley et al. 1963; Davies 1972).

Danish Greenland geology 1946 -1960: sovereignty claims and institutional conflict

During WW II the US had experienced a techno-scientific revolution, making vast amounts of technological and financial resources and manpower available to the development of the US military 'exploratory machine'. Denmark on the other hand, having tolled under German occupation, had been economically and technologically weakened, leaving a comparatively diminutive geo-scientific community frustrated by lack of scientific prospects and opportunity for action.

Through the first four decades of the 20th century, Danish sovereignty of Greenland had provided a great opportunity for Denmark to play a unique and internationally significant role in Arctic science and exploration. Not surprisingly, the end of WW II caused a release of pent-up energy among scientists and politicians to reclaim the last remains of Denmark's once great colonial empire, as an opportunity for international agency, rekindling pre-war hopes of significant finds of fossil fuels and mineral resources to support the ailing national budget.

Yet at the same time, the Danish geo-scientific community was tormented by internal competition and conflict. Before WW II, Lauge Koch –conducting large-scale expeditions in East Greenland on behalf of the Danish state– had effectively monopolized the geological investigation of the island, relying almost entirely on foreign geologists for his investigations. Professionally and economically stunted and bereft of options to partake in his prestigious and financially lucrative investigations, Koch's Danish colleagues accused him of improper scientific conduct, to which Koch responded with a lawsuit for slander. Bitter and mean, this conflict led to seriously strained relations between Koch and not only the Danish geologists, but to a certain extent also the entire Danish geo-scientific community (Ries 2002; Ries 2003; Ries 2007).

Between 1946 and 1958, when Koch retired, Denmark conducted two independent and competing state-subsidised geological surveys –GGU to the West and Koch to the East– each operating according to their own strategy and with very limited contact and cooperation. Danish presence in North Greenland converged mainly around a chain of smaller semi-private expeditions led by the archaeologist count Eigil Knuth, while, the Danish Geodetic Institute and its ambitious director, mathematician Niels Erik Nørlund, eagerly pursued topographic mapping activities, air surveys and gravimetric measurements across the island, financed partly by the private Danish mining company 'Kryolit-selskabet'.

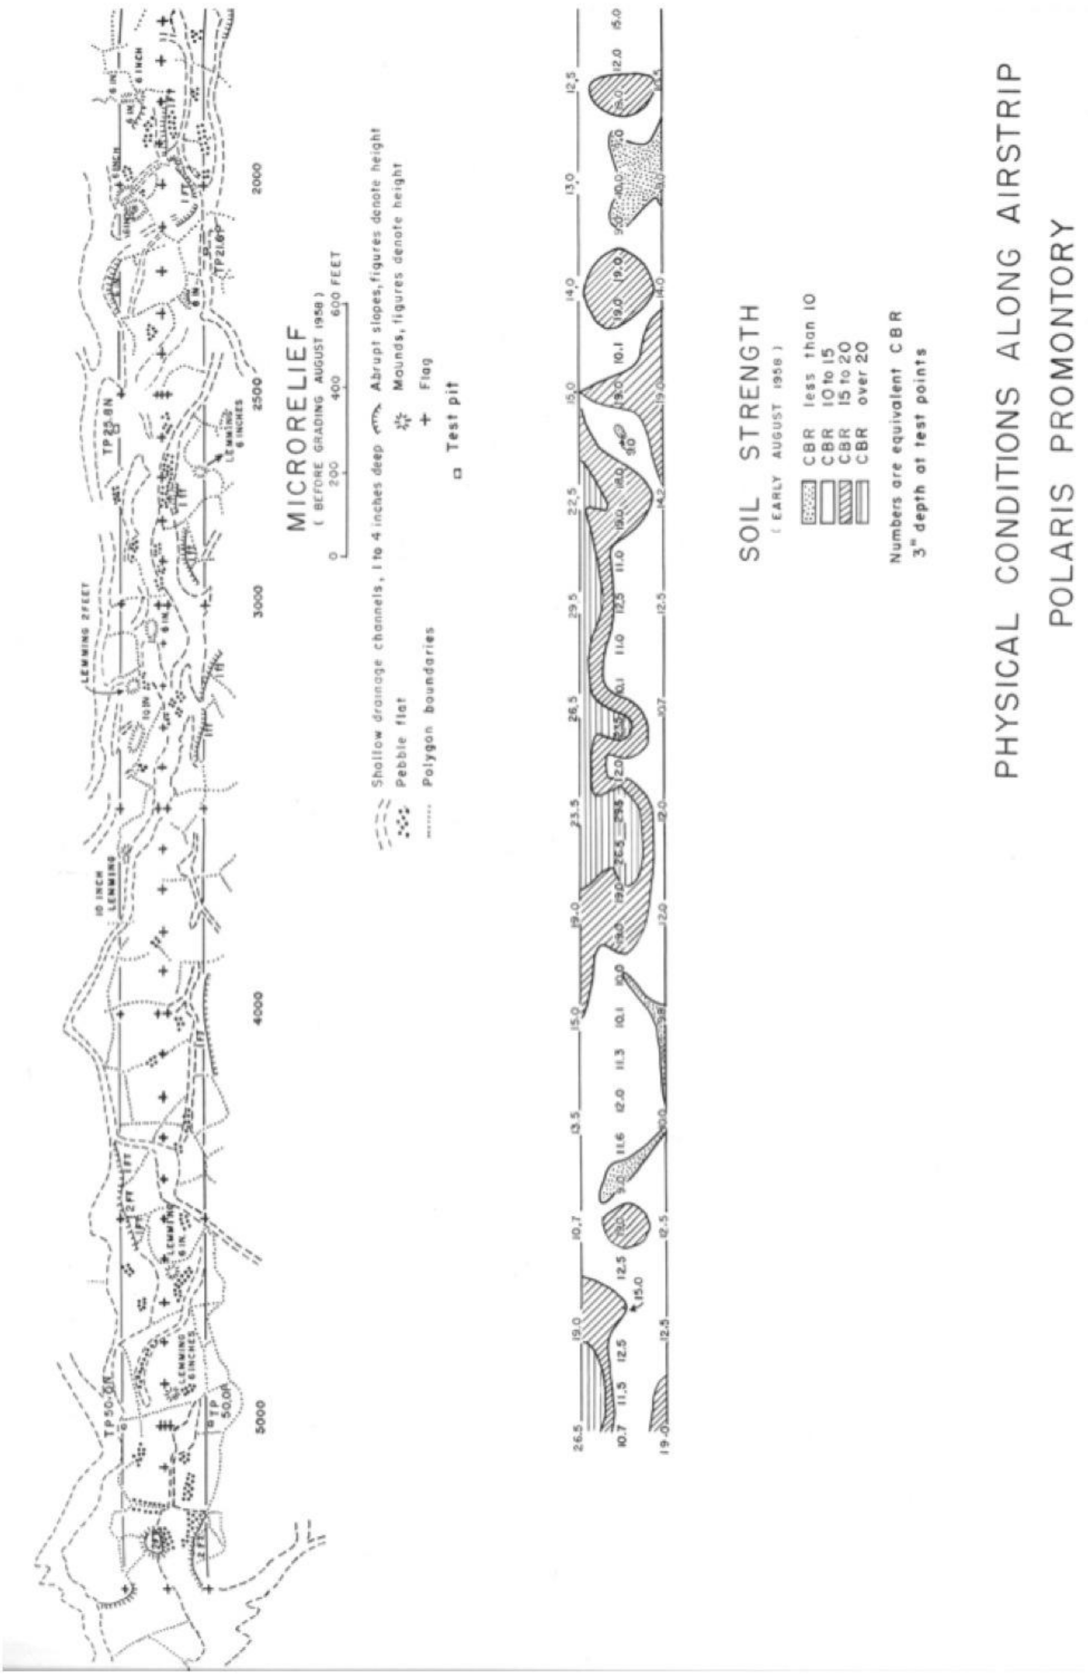

Fig. 4: Physical Conditions along airstrip Polaris promontory (Davies 1959).

In June 1945 Lauge Koch recapitulated the situation to his long-time friend Morten Porsild. Although still squarely rooted in a position as geological consultant for Director Knud Oldendow of the Greenland Administration, and with Oldendows word, that his ambition to continue internationally staffed explorations in East Greenland, Koch, was not optimistic about the future prospects of a serious and coordinated Danish geological exploration effort. In Koch's opinion, Knuth was merely an annoying disturbance; an amateur seeking only to conduct "*individual scattered investigations, mountaineering and artistic expeditions.*" His faith in the Danish geologists was not much stronger: " […] *it will be my role, in fact it is already my role to say to the director: 'The Danish geologists are not capable of the job.' "*(Koch 1945)

In Koch's own view, his 'most dangerous opponent' was Niels Erik Nørlund, mathematician and ambitious director of the Danish Geodetic Institute, who eagerly pursued topographic mapping activities, air surveys and gravimetric measurements across the island, financed partly by the private Danish mining company 'Kryolit-selskabet':

> *"Nørlund knows, that the only person capable of exposing his plans for what they really are – namely under the pretence of practical geological investigations to raise heaps of money for level measurements and a gravimetric network, which undoubtedly is of high scientific value, and will make Nørlund famous in his own circles– is me, who is honest and ruthless enough to point out, that even if Nørlund commands a large and capable crew, this has next to nothing to do with practical geological investigations."* (Koch 1945)

Practical geological investigations played an important role in Koch's own plan for a re-continuation of his geological investigations on the East Greenland Coast. Already during the 1930s Koch had located isolated small low-value deposits of coal, oil and gold on his expeditions sufficient for local use, and Koch now suggested continuing and expanding these practical investigations to include radioactive materials such as uranium and thorium (Grønland 1947). Although Koch disregarded the gravimetric measurements conducted by the Geodetic Institute marginal to practical geology, he agreed that accurate topographical maps were a precondition for any modern geological investigation. But he saw no need to wait for the Geodetic Institute to move into East Greenland, since already before the war, large enough parts of East Greenland had been topographically mapped, that it was possible to resume geological investigations in the region right away.

Arne-Noe Nygaard, once student of Lauge Koch now professor of geology at Copenhagen University, regarded his former mentor as 'a scoundrel of calibre' who should best be kept out of influence:

> *"If Koch gains footing for one year, we will have a five-year-plan on our hands […] The geologists know that they can handle him before he is established. Established, with a five-year-plan and trusted with a national task, he will be untouchable, and we will pay the price through a poisoning of our profession inwardly as well as outwardly. Geologists aren't angels, and our profession has been weakened for a number of years. We are now a small group, who do what we can and work very hard to catch up; we have a new batch of students underway and are getting to grips. Give us the right conditions and peace to work, and we will make it."* (Noe-Nygaard 1946?)

Still deeply hostile towards Koch, the Danish geologists regrouped in 1945 to form the Greenland Geological Survey (GGU) as a state institution to carry out geological investigations in West Greenland without interference from Koch. Closely aligned with the Dept. of Geology at Copenhagen University, GGU focused on general geological surveying and mapping, while serving as a training ground for a new generation of Danish geologists (Ellitsgaard-Rasmussen 1996). While GGU supported the efforts of the Geodetic Institute to provide a new and much needed topographical map of West Greenland, they were, as Noe-Nygaard explained to Oldendow, not in favour of what they feared would be premature practical investigations:

> *"Seen from the outside, it might be tempting to aim directly for what seems to be 'the raisins in the cake'. Should these raisins however turn out to be 'non-existent', we are left empty-handed* […] *in that we will still know nothing of the cake itself* […] *The conclusion must be, that a systematic geological survey should be commenced in a region, where the geodesists have completed their topographical map, and in which we from a geological point of view would expect a priori, that principal questions can be answered within a reasonable period of time."* (Noe-Nygaard 1945)

After WWII then, the Danish Greenland Administration was tasked with balancing an entanglement of different interests in a landscape of eager and ambitious actors whose mutual relations ranged from nervous to hostile, faced with the additional challenges of a strained national economy and rapid US expansion in Greenland. This was why on January 7 1947, the Danish Government decided to establish an interdepartmental board to coordinate Danish tasks in Greenland *"and especially such tasks, which during the occupation had been under American military administration*", including military and marine operations, mapping, meteorology, radio service and expedition logistics, aiming for *"increased effectiveness in addition to reasonable savings."* (Grønland 1947)

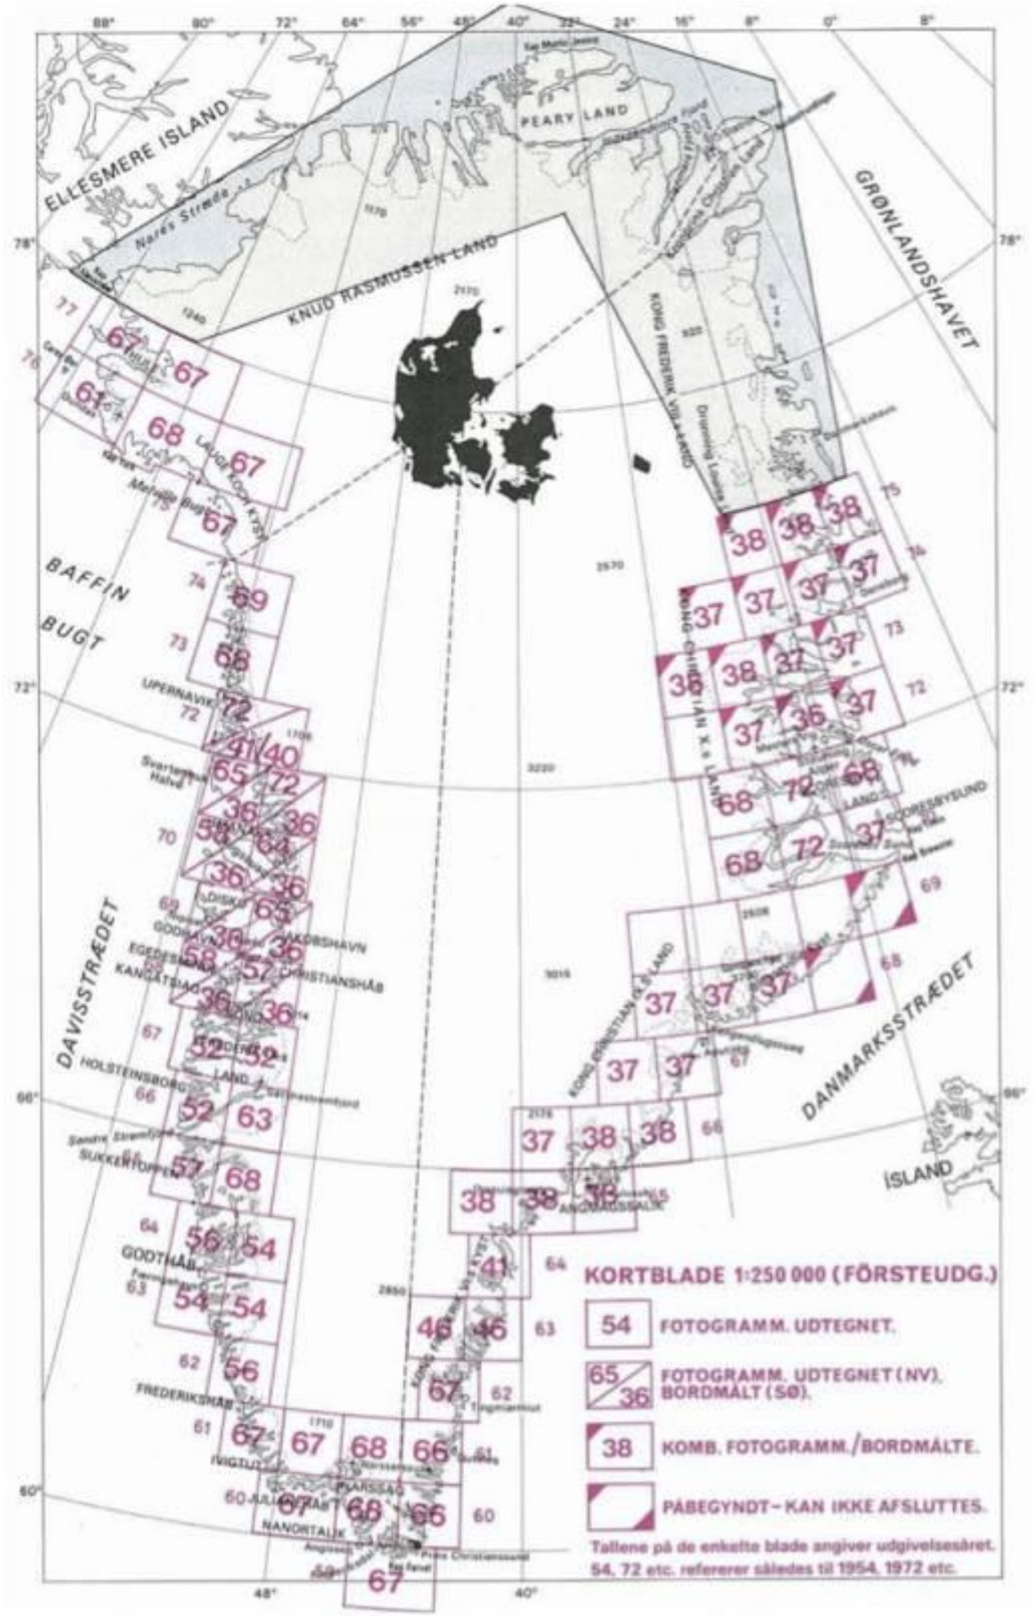

Fig. 5: Map sheets published by the Danish Geodetic Institute by 1978.
Numbers on sheets indicate year of publication (Sørensen 1978).

The board was disestablished in 1949, when Oldendow retired. In 1950, the Greenland Administration was transformed into a department under the State Ministry. In 1951, after a trial period of five years, GGU was made a permanent institution under the Greenland Administration. After Koch's retirement in 1958, GGU continued to expand its activities in close alignment with Copenhagen University, but not until 1965 did GGU begin systematic investigations in Northern Greenland, followed in 1967 by the first entry into Koch's East Greenland (Henriksen 2002). Throughout this period, Geodetic Institute continued to expand its mapping activities south of 78°N, while Knuth remained an active presence in Northern Greenland –Danish and therefore politically important. Logistically, scientifically and technologically Denmark remained dwarfed out by the Americans.

Fig. 6: Operation Groundhog 1960, left to right: William E. Davies, USGS Military Geology Unit; Count Eigil Knuth, archaeologist, Denmark; Stanley M. Needleman, project leader, geophysicist, Air Force Cambridge Research Center (Needleman 1962).

Final words

So far, the DK/US entanglements over Greenland at the geo-political level seem to have been matched by limited common interests in Greenland geology from a scientific point of view. While US geologists focused on short-term dynamic geological processes for military engineering purposes, Denmark focused on systematic structural investigations for scientific and/or economic purposes.

However, this brief paper has only scratched the surface of the history of the Danish/American geological exploration of Greenland between 1947 and 1960. Much work lies ahead to grasp not only the specific ways in which geo-political and military interests shaped American geological scientific practices in Greenland, but also how Danish Greenland geology was affected by institutional hostility and competition under the challenge of marked US presence in a post-colonial setting wrought with global military and geopolitical tensions.

CONFIDENTIALITY VS. PUBLICITY: EMERGING TENSIONS IN SCIENCE AND TECHNOLOGY DURING THE COLD WAR

Kristian H. NIELSEN
Department of Science Studies, Aarhus Universitet, DENMARK
khn@ivs.au.dk; http://pure.au.dk/portal/en/khn@ivs.au.dk

Abstract

One important tension involved in the military patronage of scientific research is that of confidentiality vs. publicity. While most military operations are based on controlling flows of information, it is commonly agreed that science needs open publishing, unrestrained communication among peers across national borders, academic freedom, and public understanding of science to flourish. With the spread of extensive military-science collaborations during the Cold War, the balancing of military needs and scientific norms became critical, not the least when it came to public understanding of science and science policy issues. This paper aims to explore the tension between confidentiality vs. publicity as a tool of Cold War Science historiography. Looking at scientific activities during the International Geophysical Year of 1957-58 (IGY), the paper provides a few examples of how military bodies and scientific organizations in practice managed the tension.

Classified vs. open science

By the end of World War II, two opposed conceptions of science had emerged: classified vs. open science. On the one hand, science had proven highly efficient as a tool of military technology. The Manhattan Project, led by the USA with participation from Britain and Canada, which led to the development of the first atomic bomb, clearly demonstrated that focused and organized research could result in technological achievements of unprecedented military-strategic importance. The Project began as small research program and eventually employed more than 130,000 people doing research and production at more than 30 sites. Also, the Manhattan Project was charged with intelligence gathering on the German nuclear energy program, seizing materials, personnel, and other resources at any given opportunity. Placing tight restrictions on the flow of scientific information, dictating remote site locations, and required subterfuge in obtaining labor and supplies, the Project was a highly secretive endeavor, which served as a constant irritant to the scientists involved (Atomic Archive, 2011; Kelly, 2007; Stoff, Fanton, & Williams, 1991).

Whereas the Manhattan Project established the military value of classified science, many scientists and sociologists of science at the time firmly believed in and frequently endorsed the ideal of open science. For example, in 1942, sociologist of science Robert K. Merton, provoked by what he and many others saw as the exploitation of science by Nazi Germany and other totalitarian regimes, published an article on the normative structure of science (Merton, 1973 [1942]). Merton's norms included:

- *Communalism* (Merton used the term *Communism*): Scientific results are the common property of the entire research community.
- *Universalism*: All scientists regardless of race, nationality, culture, and gender can contribute to science.
- *Disinterestedness*: Scientists should not present their findings entangled with their personal beliefs or activism for a cause. In other words, scientists should maintain an arms-length attitude to their own findings.
- *Organized skepticism*: All scientific claims must be exposed to critical scrutiny before being accepted.

Merton's norms prescribed an open and disinterested attitude to scientific claims and findings on behalf of all scientists. At the same time, Merton clearly envisaged a link between the micro-society of scientists and a properly democratic macro-society. The open society, to use Karl Popper's term, was fully compatible with the ideal of open science – indeed, the two feed on each other (Kitcher, 2001; Popper, 1945). The close link between democratic societies and science, however, also meant that science had to be open to influences from society. In Vannevar Bush's 1945 report to the President, *Science—the Endless Frontier*, which proved highly influential with respect to US science policy, the freedom of science was tightly coupled to the progress of society. Because of its huge implications for health, public welfare, industry, and national security, science was a proper concern of Government, Bush argued (Bush, 1945). The openness of science in a democratic society based on social welfare and economic growth not only pertained to the communication and sharing of results, but also to political and military planning of scientific research.

Science and public policy

Vannevar Bush recommended that a single new agency should be established to provide Government support of science, or more precisely, in the words of William A. Blanpied (1999), "to support the self-directed basic research of university scientists." The agency envisaged by Bush was not realized until 1950. Instead, a Presidential Scientific Research Board was charged with reviewing current and proposed activities both within and outside the Federal Government. Its report, *Science and Public Policy*, came out in 1947, recognizing the need for finding a "workable compromise" between scientists' call for open science and the military's and the Government's need to keep some scientific results secret (Steelman, 1947, p. 35).

In particular, the Steelman Report, named after the chairman of the committee, made a distinction between the need for freedom of scientific inquiry and the need for national security. Freedom was not part of Merton's normative structure for science, see above. But freedom was highly stressed by Vannevar Bush in his *Frontier* report:

> Many of the lessons learned in the war-time application of science under Government can be profitably applied in peace. The Government is peculiarly fitted to perform certain functions, such as the coordination and support of broad programs on problems of great national importance. But we must proceed with caution in carrying over the methods which work in wartime to the very different conditions of peace. We must remove the rigid controls which we have had to impose, and recover freedom of inquiry and that healthy competitive scientific spirit so necessary for expansion of the frontiers of scientific knowledge. (Bush, 1945, Chapter 1.4)

The Steelman Report fully acknowledged this view on freedom, putting it down as "the views of scientists" (Steelman, 1947). The opposing view was equally recognized, namely that freedom for science requires democratic institutions, which cannot survive or thrive without strong national security measures. Modern warfare, it was argued, is total war, involving all of the resources of the nation. Scientific knowledge, bearing upon people, education, industry, agriculture, military, etc., therefore, is vital to national security and must be considered secret and kept under strict security regulations (p. 35).

However, the report further argued, search for an acceptable middle way between the two extreme viewpoints for security and freedom of science was required. Some leading military officers, Government officials, and politicians recognized the importance of scientific freedom; among the scientists, the need for some degree of security was also acknowledged. Besides the personal awareness of the other parts needs and requirements, some of the following measures were recommended in order to guarantee secrecy on scientific work (p. 36):

- *Compartmentalization*: No individual should know more about the total project than is absolutely necessary for him to work effectively.
- *Classification*: Indicating the degree of precaution to be used in safeguarding factual knowledge against unauthorized disclosure.
- *Loyalty checks*: Ensuring that every scientific worker and every other employee engaged in scientific research is completely loyal to the US as well as thoroughly discreet.

The tension between secrecy and freedom, the Steelman report maintained, had to be solved by means of a workable compromise. Strict military security in the narrow sense was not seen as consistent with the full flowering of free scientific inquiry, which again was one of the broader requirements of national security. The US, being in a unique situation because of its advanced technology, had nothing to fear from the free circulation of scientific knowledge, the Steelman Report concluded:

> On the contrary, as a people we have a real national interest in such circulation, in the certainty that we can apply basic discoveries with the same ingenuity and technical skill and speed we have displayed in the past. **Security regulations, therefore, should be applied only when strictly necessary and then limited to specific instruments, machines or processes. They should not attempt to cover basic principles or fundamental knowledge.** (Bold in original: Steelman, 1947, p. 37)

Science and foreign relations

The difference between classified and open science was more than a tension for post-war science policy-makers. It also served as a constructive way of dealing with, or rather including science into US foreign policy. Classified science was helpful to the US military in terms of knowledge production, technical innovation, and scientific intelligence, aimed at increasing the US strategic advantage. Open science, for its part, played an important role in the ideological struggle of the Cold War. As we shall see later, promoting open science in public became a way for scientists and science policy-makers in which to demarcate Western science from Communist science, thus making the link between open science and open society useful as a weapon in the clash between ideologies.

During the Cold War, the USA and the Soviet Union both attempted to build empires that strived for ideological hegemony by a number of different means such as diplomacy, psychological or political warfare, European reconstruction, intelligence, nuclear deterrence, etc. This was recognized by contemporaries, cf. the Steelman report cited above, and this recognition today forms part of the so-called "new historiography of the Cold War": According to Gaddis (1997), the Cold War resulted from a diversification of power, rather than a balancing of (military) power. Whereas, previously, historians have tended to see the power struggle of the Cold War as a bipolar battle between nuclear superpowers, we now recognize that, during the Cold War, the exercise of power also took place on ideological, moral, economic, technological, scientific, and cultural grounds. Communication and cooperation were "weapons" of the Cold War just as conflict and coercion. Ultimately, the Cold War did not end because one of the two superpowers acquired military superiority –in fact, the nuclear arms race seemed to have prolonged the Cold War rather than end it. What did end the Cold War was the superiority of the "soft power" of the USA: liberal-democratic and capitalist values, mass consumption culture, and the proliferation of private companies and public institutions organized in accordance with American ideals.

By the end of World War II, some US scientists such as Vannevar Bush clearly saw the need to bring closer together science and State affairs. Others, such as those engaged in the International Science Policy Survey Group (1950), led by Lloyd V. Berkner, also considered scientific cooperation, communication, and intelligence as pivotal elements of science in relation to government and foreign relations. The basic premise was that, in order to make American foreign policies effective, it was deemed necessary –the report cited Secretary of State Dean Acheson on this point, to make such policies articulate through all the institutions of our national life, including science being "an important element of American culture" (International Science Policy Survey Group, 1950, p. 9).

The American government, the International Science Policy Survey Group (1950) argued, would have to take an active stance in promoting scientific advances, in particular "research that can be beneficial to ourselves and our Allies" (p. 4), collaborations between scientists in the USA and abroad, and the free flow of scientific information all around the world. Advancing scientific collaboration and communication potentially would have three important consequences: 1) it would provide scientists (and intelligence officers) with cutting-edge knowledge about the progress of science and the state of scientific institutions in many countries (also countries on the other side of the Iron Curtain, it was hoped); 2) it would help place topics deemed fundamental to American science, technology, industry, and policy on the research agenda of other countries' research programs; and 3) it would enable the spread of democratic and liberal values, which were thought to be inherent to science and to the American way of life, around the globe (International Science Policy Survey Group, 1950).

Trained as radio engineer and ionospheric physicist, Berkner spent a significant part of his professional life mediating between science and foreign policy in the USA during the first part of the Cold War (Needell, 2000). His second State Department assignment, after the *Foreign Relations* report, was facilitating Project TROY, a top secret study group of twenty-one scientists, social scientists, and historians, most of whom were academics. Project TROY engaged brilliant minds in thinking about the problem of "getting the truth behind the Iron Curtain", i.e. the truth about ideologies and forms of government on both side of the Iron Curtain. As explored by scholars such as Kenneth Osgood (2006), psychological or political warfare formed an important part of the American response to the Cold War. The Project TROY report in particular analyzed the problem of getting information into enemy territory (Needell, 1993). Converting the minds and hearts of the population, it was believed, would enable a "rollback" of Soviet influence in the Eastern Block. Another element of psychological warfare envisaged by the Truman and the Eisenhower Administration was presenting US policies to an international audience in order to convince them of the peaceful and collaborative attitude of the Americans. One example is provided by the Atoms for Peace Campaign enacted by President Eisenhower (Osgood, 2006, pp. 153-180). Importantly, the campaign involved many strategic communication activities, all of which aimed to show the American initiative as a way in which to promote scientific advance, technological progress, and material welfare all around the globe (see Figure 1).

Fig. 1: The Atoms for Peace postage stamp, designed by the US Postal Service in order to promote Eisenhower's campaign.

Balancing secrecy and openness: the making of the International Geophysical Year 1957-58

The Cold War provided leading US scientists with many occasions to get together and discuss collaborative efforts and funding opportunities (Kevles, 1990). One example, which evolved into an international scientific endeavor, was the International Geophysical Year 1957-58 (IGY), described in numerous publications (for an overview of the historiography of the IGY, see: Launius, 2010). Too much of this writing has tended to overlook the importance of the Cold War setting of the IGY, highlighting, with a slant of sensationalism, the scientific planning, collaborations, and contributions. However, as Fae Korsmo (2009) emphasizes, "basic science and military objectives both were motivations" (p. 24).

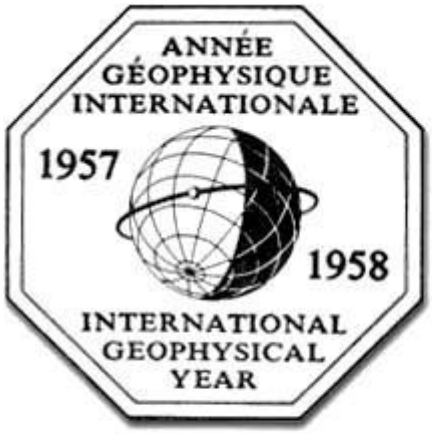

Fig. 2: The original IGY logo depicts planet Earth with no geographical or political features. The one circulating celestial body symbolizes the US and Soviet programs to launch artificial satellites. With its atomic connotations (compare Figure 1), we might in hindsight see the encircled globe as being entirely enclosed in a titanic nuclear struggle.

The tension between classified and open science is directly reflected in the ways in which the story of the origin and context of the IGY is depicted (see Figure 2). By far most accounts see the IGY as a prime example of open and free scientific inquiry. Such narratives usually begin with a dinner conversation that took place in the home of James Van Allen, then leader of a high altitude research group at Johns Hopkins University, on the evening of April 5, 1950. The dinner party included Sydney Chapman, British geophysicist, Lloyd V. Berkner, and three other geophysicists: J. Wallace Joyce, Fred Singer, and Ernest H. Vestine. According to Van Allen:

> The dinner conversation ranged widely over geophysics and especially geomagnetism and ionospheric physics. Following dinner, as we were all sipping brandy in the living room, Berkner

> turned to Chapman and said, "Sydney, don't you think that it's about time for another international polar year?" Chapman immediately embraced the suggestion, remarking that he had been thinking along the lines himself. (Van Allen, 1983)

The open narrative of the IGY then proceeds with Berkner and Chapman, three months later, presenting their ideas at the meeting of the Mixed Commission on the Ionosphere in Brussels. The Commission was one of several of such bodies, designed to bring together men from various international scientific unions with a common area of interest. The participants recommended the proposal to the scientific bodies represented in its membership and to the International Council of Scientific Unions (ICSU). ICSU, a nongovernmental body supported by UNESCO, embraced the idea, securing its internationalist, scientific aspirations. In the fall of 1951, the ICSU Executive Board met in Washington and decided to create a special committee to work on plans for what was still being referred to as the Third International Polar Year. Later, by recommendation of Chapman, it was decided to change the name to International Geophysical Year. The scientists decided that the IGY should run for eighteen months, from July 1, 1957, through December 31, 1958, a period which would coincide with an expected peak of sunspot activity as well as several eclipses. Many nations formed IGY scientific committees to organize national efforts –sixty-seven national scientific teams were involved. In the US, the National Academy of Sciences persuaded the Government that it should underwrite a major US effort. Making explicit the scientific, international driving forces of this version of the story, one of the popularizers of the IGY, Walter Sullivan, in *Assault on the Unknown*, describes the IGY as "a scientific club. To gain admittance –that is, to be included in the IGY program– a scientific project had to be concerned with 'specific planetary problems of the earth'" (Sullivan, 1962, p. 30).

The view of IGY as a purely scientific effort may be contrasted with the historical narrative that places the IGY in a Cold War setting. Allan A. Needell (2000), historian of science and curator of space history at the Smithsonian, notes that it probably was no coincidence that Berkner's suggestion at the Van Allen appeared right after the publication of the *Science and Foreign Relations* report (see above). Even though the Polar Year proposal, at least at first, was pursued quite independently of specific national security projects at the time, Berkner and others, who played a double role ad scientist and Government adviser, made every effort to ensure a seamless blending of science and national security. A case in point is the 1950 recommendation, which emerged from a panel under the US Research and Development Board, to establish ionospheric observing stations along the 75° west meridian linking a north-south chain of stations with existing US-Canadian installations. Within a year, the proposal was adopted in the concept of the Third International Polar Year, and the three meridians chosen in 1952 for extensive ionospheric observation did include the 75° west. Arguing that it was not simply the case that the choice of meridians was good for the military, but bad for science, Needell (2000) explicitly warns against making too much of this circumstance (p. 302). Still, it was the case that scientific advisers such as Berkner actively mediated between national security and scientific interests. With respect to Berkner's active role in organizing the IGY (he served as one of the core members of ICSU's Comité Spécial de l'Année Géophysique Internationale), Needell (2000) remarks:

> Berkner continued to welcome and refine the complex roles of scientific advocate and broker between the realms of science and national security. […] secrecy, and contradictions between norms and values current in the different realms, seemed ultimately to be manageable as long as they remained effectively compartmentalized and their overlap remained unpublicized and under the management of a few discreet, well-placed, and experienced individuals. Juggling scientific values and national requirements was Berkner's special talent and increasingly his most powerful calling. (p. 307)

Another historian of science who has emphasized the carefully managed relationship between science and national security in the making of the IGY is Rip Bulkeley (Bulkeley, 2000, 2010). Bulkeley (2010) notes that, although scientific interests have been strongly promoted by IGY founders as the only incentive to commence on the huge international collaboration and competition, other factors too were decisive. The Cold War, of course, was the overarching political framework in which the IGY made equally sense to scientists and politicians. The scientific networks mobilized during World War II to forecast weather, trace ocean currents, detect ionospheric dynamics, etc., were not only extended, but also improved in the course of the Cold War (Doel, 2003). Along with a number of current domestic affairs, scientists and policy-makers had every reason to use the impetus to the geophysical sciences to serve scientific ideas as well as US foreign policy.

A short conclusion

The IGY serves as a prime example of the tension between confidentiality and publicity that emerged during the Cold War. For practical as well as ideological reasons, scientists increasingly sought military and political backing. They carefully had to manage their projects such as the IGY balancing the open norms of science and the closed world of the military/foreign relations. The IGY serves as a (successful) reminder that the tension not only was problematic, but in some cases proved too highly fruitful. Confidentiality and publicity provided scientists with two strong ideological, political and scientists resources during the Cold War.

POLAR RESEARCH AND THE ENDINGS OF THE COLD WAR

Stian BONES
Department of History and Religous Studies, Universitetet i Tromsø, NORWAY
stian.bones@uit.no

Abstract

Throughout the Cold War, the scientific efforts would serve many political interests. It is not difficult to find examples where science was attached to a political strategy –both in the East and in the West– which focused on power-oriented manoeuvring. This also holds to be true for the activities of the Norwegian Polar Institute (NPI). For decades it seemed to be some kind of a leitmotiv for the NPI not to let any of the Great Powers, and especially not the Soviet Union, get such advantages at Svalbard or in any other strategically important areas, that it loosened up or threatened Norway's sovereign rights. But this is not the whole story. Another strategy was also always evident in polar research, the one that was oriented towards true international cooperation, and this strategy will be described in this presentation. On the basis of the rich source material from the NPI, we will analyse the role that NPI and polar research played towards the end of the Cold War. Polar scientists from several countries –Canada, Denmark, Norway– invited partners in the Soviet Union to a closer cooperation, and when Gorbachev took seat in the Kremlin in 1985, this also laid a new foundation for polar research throughout the whole Arctic region.

Where were the drivers behind a wider scientific cooperation between the West and the Soviet Union throughout the Cold War? Many explanations must be taken into consideration, and in this presentation I only hope to shed some light on a few.

The political development inside the Soviet Union mattered much. This is certainly true for the period after Stalin's death in 1953 –with Khrushchev's attack on Stalinism, and eventually, with the abolishment of Stalin's severe strategy of scientific screening. It made it possible for the Soviet Union to take part in the IGY, and in many international scientific bodies. As for the 1980s, Gorbachev and the end of the Cold War, I will return to that.

Important was also the general trend towards lower political tensions after "the deep Cold War years 1947-53", particularly during the détente period after the Cuban Missile Crises in 1962.

In addition, and with special relevance for this Symposium, are the many scientists –both in the West and in the East– who believed in scientific internationalism; that they were not just servants of nations, but also of the "Republic of letters" –the international scientific community–, and thereby serving humanity.[1] One of the best coverages of this is Matthew

[1] More on the concept, see Sverker Sörlin, *De lärdas republic. Om vetenskapens internationella tendenser*, Malmö 1994.

Evangelista's book, *Unarmed Forces*.[2] He shows how physicians and other scientists managed to form transnational networks which eventually gave a decisive impetus behind Gorbachev's "new thinking". These networks certainly made a difference.

While Evangelista is primarily focusing on the work that was done to prevent a "nuclear showdown", for instance by the Pugwash movement, I believe that also other scientific fields and disciplines are, to some extent, comparable to this.

International contacts forged through scientific cooperation contributed to a lasting dialogue that helped to ameliorate the antagonism of the Cold War, Evangelista states.[3] So there *was* an option for scientists to work as political bridge-builders. I believe that Evangelista would agree if we rephrase this sentence slightly, and state that also scientific *problems* – the common challenges shared both by Western and Eastern scientists– might work convergent. The case of Soviet-Norwegian cooperation in polar research can illustrate both of these trends.

* * *

Norway was the only European NATO member bordering the Soviet Union. This "neighbourly asymmetry" was no doubt the most important foreign policy question throughout the cold war, and thus it can be argued that Norway was in fact *forced* into some sort of cooperation with its powerful neighbour. To some extent this can serve as an explanation, but as an overall explanation, it falls short of evidence.

The scientific field where Norway and the Soviet Union established the closest and most lasting cooperation, was in marine research. The cooperation started up in 1956, as a result of a joint political and scientific initiative from the *Norwegian* side. The Norwegian Prime Minister, Einar Gerhardsen, saw the thaw under Premier Nikita Khrushchev as an opportunity to move into a political dialogue with the Soviet Union, and suggested that marine research might be one of the suitable channels. The Institute for Marine Research was also interested in this, and leading scientists there saw the newly established contacts as an opportunity of getting access to Russian data sets and to improve their models. Although the continued contact was formally taking place under international or regional agreements (such as ICES and NEAFC)[4], the Soviet-Norwegian cooperation proved so successful that fishery cooperation was formalized by means of two *bilateral* agreements in 1975 and 1976. In effect, both the Norwegian and the Soviet management of the fish stocks in the Barents Sea from 1976 were carried out on the foundations of a joint scientific effort.

Marine research can be described as the Soviet-Norwegian success story, but what about other disciplines in the natural sciences? This brings me to the Norwegian Polar Institute, and this institution will be at the centre of the rest of my presentation.

The Polar Institute was Norway's principal research institute in the Polar Regions, and was also given the demanding task of surveying and mapping Norwegian Polar territories, both north and south. In addition it functioned as a consultative organ for many ministries, especially the Ministry of Industry (which was responsible for the Polar Institute), the Ministry of Justice, the Ministry of Foreign Affairs, and (later on) the Ministry of the Environment, which took over the responsibility for the Polar Institute in 1979. As the Director, Tore Gjelsvik, put it in 1973: "One can therefore not see the Institute only as a research institution, since its structure and multi-disciplinary activity make it a useful instrument for the authorities in the forming of Norwegian polar policy". "It feels a responsibility", Gjelsvik stated, "for guarding our national interests in a border area, and has been able to warn and help the authorities in connection with crisis types of situations both in the north and in the south".[5]

The IGY provided, for the NPI, a good example on how "Norwegian interests" could be best served. An effective international cooperation in the Antarctic helped temper the antagonism between East and West, which was of course positive for a small state such as Norway, but indeed also for the international community as a whole.

Norway's primary goal was to establish multilateral agreements also on Arctic research, and to strengthen already existing international organisations. The Director of NPI, Tore Gjelsvik, who was Norway's national delegate to the SCAR meetings and the president of SCAR 1974-78, tested out various possibilities. One idea was to expand the scope of SCAR

[3] One might, although very simplified, operate with two possible strategies which can serve as analytical tools. One would be leaning towards dialogue, internationalism and, perhaps, transformation of the international system (where "open science" and open societies would prevent or force back totalitarian tendencies); the other would be leaning towards scientific screening and block-building towards the totalitarian competitor, which would require "closed science".

[5] Susan Barr, *Norway – A Consistent Polar Nation? Analysis of an Image seen through the History of the Norwegian Polar Institute*, Oslo 2003, p. 376.

so that it also included Arctic research. Before a SCAR meeting in Oslo in 1970, the idea was presented to the member states, but with limited success. Especially the southern member states resented it.[6]

But Gjelsvik didn't give up. In 1972 he invited what he considered the three most "representative" leaders of polar research in the US, Canada and the Soviet Union to Oslo. The theme was once again prospects for a future multinational scientific cooperation in the Arctic.[7] But the soviet representative, Alexey Threshnikov, leader of the Arctic and Antarctic Research Institute (AARI) 1960–81, said quite openly that although soviet scientific institutions were certainly interested, it was politically impossible. Behind this Soviet political imperative stood the State Committee for Science and Technology (GKNT), Gjelsvik believed; they were real decision-makers in matters like these. The State Committee's political strategy was instead to establish cooperation on Arctic research on a bilateral basis.

What now, then? Norwegian authorities chose to try and establish a bilateral agreement, as the State Committee had suggested –both out of political and scientific considerations. It was obvious, Gjelsvik thought, that both Norwegian and Soviet scientists would benefit from a closer cooperation in for instance geology, oceanography, sea ice research, or biology. A Foreign Ministry memorandum emphasized the following:

> From a political perspective a developed Norwegian/Soviet co-operation in the implementation of concrete research projects must in principle be perceived as positive – provided such projects are genuinely academically/scientifically based.[8]

In fact, many valuable contacts were already established. As early as 1968, for instance, NPI's meteorologist and sea ice researcher Torgny Vinje was invited on a truly pioneering visit to one of the Soviet floating research stations –*North Pole 18*. Vinje, who by the way was at the time also affiliated with a NATO research project on "Military Operations under Arctic Conditions", had a strong scientific motivation for broadened contacts –it was crucial as a means of reaching a comprehensive understanding of how the Barents Sea functioned as a kind of "intermediary" between the Arctic Ocean and surrounding seas.

In 1974, delegations met, they had lengthy discussions, but in the end, no agreement was reached. The reason was solely political: The Soviet side insisted that cooperation should relate only to Svalbard. That was of not acceptable for Norway –both out of scientific and political considerations.

Now ten years passed with no significant changes, but in June 1984 there was a new sign of progress. The Director of Foreign Relations of the powerful State Committee for Science and Technology, Nikolaj Borisov, visited the Polar Institute. He came with an outstretched hand concerning a Polar research agreement that would also provide access to parts of the Soviet Polar Regions.[9] Thus the "Svalbard threshold" had been crossed and it was possible to go further. The Norwegian side proposed starting up with "research topics affecting both countries", such as biological research, oceanography and upper atmosphere research (cosmic physics).[10] On these terms, an agreement was finally reached in 1987.

Seen from a political point of view, the agreement was remarkable. It established, for the first time, a "geographical balance" between Norway and the Soviet Union, making it possible for Norwegians to do research in Soviet waters.

However, there is solid documentation that the geographical working area covered by the agreement was as much the result of *scientific* rationale. Several of the scientific programmes were for instance characterized by the new ecological systems theory that developed in the course of the 1980s, especially the programmes directed towards environmental investigations and monitoring. The agreement that was signed between the Polar Institute and the Murmansk Marine Biological Institute includes the statement that "the Parties […] recognize the fact that Svalbard, the Barents Sea and the Western Soviet Arctic probably form an ecological entity".[11]

Other programmes as well, such as the four-year Soviet-Norwegian Oceanographic Programme (SNOP), led by the above-mentioned Torgny Vinje, were affected by this theme. The main aim of the geophysical programme, which was

established in 1988, was to study the transport of water and ice through the straits from Greenland in the west to Franz Josef Land in the east, but also to model development of the circulation in the Barents Sea.

Why were the efforts to realize the Norwegian-Soviet Polar research cooperation successful during the 1980s? As I mentioned earlier, cooperation was viewed positively from the Norwegian side, even though there were some reservations. What primarily explains how the reservations were overcome, is the changes in the Soviet approach to Arctic cooperation, but also to an increasing desire to overcome long-standing opposition from the Western side. Here, Canada and Norway in particular, had a role to play, it seems.

In 1984, Canada and the Soviet Union agreed to formalize research cooperation in the Arctic, and the Norwegian authorities were kept well informed about this process. It was in the wake of this Canadian-Soviet agreement that the Norwegian-Soviet cooperation also became a reality. At the same time, this closer East-West dialogue also contributed to promoting another idea of old, namely the notion of a permanent scientific cooperative forum linked to the Arctic. Canada and Norway collaborated in this work, which was eventually led by Norway, with the Director of the Polar Institute, Odd Rogne, as one of its assets.

When Mikhail Gorbachev became General Secretary of the Communist Party of the Soviet Union in 1985, contact had already been established with individuals at a high level in the decision-making hierarchy on the Soviet side, and this provided the basis for a steadily improving relationship. This was particularly the case with regard to Nikolay Borisov. When Gorbachev made his famous “Arctic Zone of Peace”-speech in Murmansk in 1987, of which research cooperation in the Arctic was one of the pillars, sources from the NPI indicates that Nikolay Borisov was responsible for this section.[12] And of course behind Borisov’s input there was a Canadian-Norwegian initiative.

On the Western side, the Murmansk speech was greeted as a clear Soviet declaration of intent to develop cooperation with the West. It was also interpreted thus by Director Odd Rogne, who –together with Fred Roots of Canada– was able to lead this process further, to the foundation of the International Arctic Science Committee (IASC) in 1990. The secretariat was based in Oslo, and Odd Rogne became its first General Secretary.

I have no sources, and have seen no analyses, that indicates that the transnational aspirations within Arctic research had the same kind of significance that the cooperation within, say, nuclear physics. But I do think that it mattered –both during the cold war, towards the end of the conflict, and as a very important means of contact in the unstable transition period which followed in the beginning of the 1990s.

ATOMIC ENERGY
IN THE PUBLIC SPHERE

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 880.

THE DEVELOPMENT OF A PUBLIC IDEA OF ATOMIC ENERGY IN THE FRANCOISM (1945-1964): THE ROLE OF THE OFFICIAL NEWSREEL NO-DO.

Felipe E. RAMÍREZ
Universidad Autónoma de Madrid, SPAIN
felipe.ramirez@uam.es

Abstract

The NO-DO, the official newsreel of Francoism, was for twenty five years a monopoly of information in the mass media. One of the most unexplored and yet unravelled aspects relate to the central role that NO-DO had in the broadcasting of scientific news and technical advances. The scientific point of view offered by NO-DO definitely contributed to elaborate a common view in the Spanish public for that period of time.

Particularly relevant to study in deep is the public image spread from Franco's regime regarding atomic energy, an official vision that underwent strategic changes according to Franco's domestic and foreign policies. Over the years, the official vision of "the atomic affair" moved from a terribly dangerous weapon towards the hopes for health and the promise of an unlimited energy resource. The NO-DO launched through nearly two hundreds news during twenty years, and became the media in charge of broadcasting to Spaniards both the fear and the hopes.

Moreover, Francoism, aware of the power of atomic energy, employed it as an instrument representing to the Spaniards the fragile equilibrium in the world of that period, as well as a matter of anti-communist propaganda. The Spanish atomic endeavour was one of the outstanding manifestations of the Spanish-nationalism spirit and importantly, a rationale to justify the political regime to the citizens.

The aim of this presentation is to state some of the style features used in NO-DO to develop a particular public perception of "the atomic affair" close to the regime's one. Indeed we will present data supporting the hypothesis that NO-DO contributed to the efficient spreading the official ideology to the public going to the movies.

Introduction to the newsreels

The role of the newsreel as a source for the study of history and, in particular, the history of science in the 20th century has been re-evaluated in recent years. However, there have been few studies to date devoted to studying the science and technology content included in those audiovisual presentations.

The case of the Spanish newsreel is special in a global context. The official newsreel created by the Franco regime in 1943, the NO-DO, had some characteristics that distinguished it significantly from other newsreels. NO-DO was created with a monopolistic nature, bringing together all of the audiovisual information filmed and screened in Spain. Moreover, its projection was mandatory at all sessions in all Spanish cinemas before the movies in the main programme. This meant the only filmed news the Spanish people saw for 20 years was that screened by NO-DO. Unlike other countries, Spanish TV did not have an extensive presence in Spanish homes until well into the 1960s. This is why the time frame of this presentation only extends to 1964, the plausible date of the end of the newsreel monopoly.

National and international

The science and technology content gathered by NO-DO was abundant and constant throughout the period 1943-1964. Our research has recovered over 2,000 news items relating to this topic, covering very different content. However, three themes had a specific role in NO-DO newsreels: aeronautics, aerospace technology (the conquest of space) and technology related to atomic energy. These issues are distinguished from others because they were **permanently** included in the newsreel schedules over this period. This makes NO-DO an invaluable long-distance narrator of the advances made in these three areas of science and technology. In this way, NO-DO built a sequentially filmed history of science in the second half of the twentieth century. This is the primary value of the newsreel.

We will focus our attention on technologies related to atomic energy.

Description of the news found in the file

From 1945 to 1964, 145 news stories related to atomic energy have been found in the NO-DO Historical Archive.[1] The geographical distribution of these news items is shown in the following graph, in which it can be seen that the United States provided most of the news (61%). Only 19 news items (12.75%) are of Spanish origin.

New discoveries in physics, new applications of atomic energy, the development of the cold war and political interests on their use determined the contents in the newsreels. These contents can be classified into:

- atom bomb explosions.
- nuclear armament.
- application of isotopes in medicine.
- the use of atomic energy in transport with special emphasis on nuclear submarines .
- popular science through exhibitions about nuclear energy .
- safety in the treatment of radioactive elements and waste.
- nuclear power plants for the production of electrical energy.
- passive defence and war.
- basic scientific research.
- political issues.

This presentation will focus only on the atomic explosions and their representation in the news. We have chosen three paradigmatic events: the bombing of Japan, the Bikini Atoll test and the news of the first Soviet atomic test.

[1] From now on we'll use the convention for references to the news: "NO-DO number of issue- Edition of issue (A,B or C), TITLE OF THE SECTION WHERE THE NEWS WAS INCLUDED, *Title of the news*, Date of the issue opening."
For example "NO-DO 143-B, UNITED STATES, *Research on the developing of the atomic bomb. The New Mexico test experiences,* 09/24/1945", makes reference to the news opened on September 24th, 1945 in the issue numbered 143, edition B down the section "United States" and under the title "Research on the developing of the atomic bomb. The New Mexico test experiences".

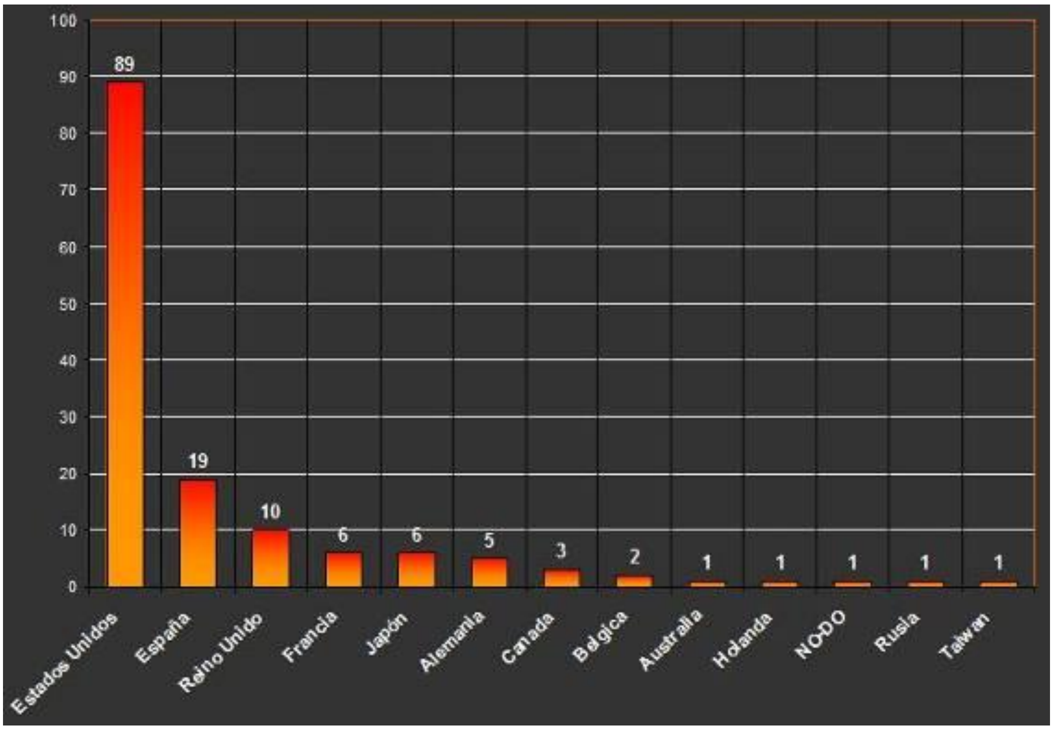

Fig. 1: News about atomic energy by country (1945-1964).

Atomic explosions

It is very important to point out that although the news items covered were put together and distributed by NO-DO, the Spanish news agency was a mere recipient of this material. It had no control over the material received, which was administered by the USA tailored to its own needs and objectives. The secretive and sensitive nature of the material concerning atomic explosions, along with the NO-DO editorial team's inexperience in these specialised subjects must be taken into account if we are to properly understand the role of NO-DO.

The identification of atomic energy with destruction and nuclear bombs was the common thread of the information included in the newsreels until the early years of the 1950s. These explosions were the events that most contributed to the forming of "*atomic*" in the public's mind. The representation of nuclear energy in the newsreels later evolved to show the non-military applications of atomic energy, although the detonation of atomic bombs never totally disappeared from NO-DO programs.

The news

The destruction of the Japanese cities of Hiroshima and Nagasaki were the first news items that made reference to an atomic explosion. The series of reports on the Japanese devastation and the initial atomic experience screened in Spain was divided into three stories in 1945, with a very different treatment of the news.

I. The atom ends a war.

The first of this news[2] summarized the military conflict between the Allies and Japan and the final surrender. Very brief images of the atomic explosions over Hiroshima and Nagasaki were inserted into a montage of images from the Pacific War. The text made no mention of the atomic bomb, or the number of deaths or damage caused.

II. Atomic energy. A matter of Science.

The second piece of news that the Spanish saw about atomic energy dealt exclusively with the research prior to the detonation of the bombs in Japan.[3] The creation of the first atomic bomb was represented as the product of a long and

---

[2] NO-DO 142-A, VICTORY OVER JAPAN, *[…] The atomic bomb over Japan […]*, 09/17/1945.

[3] NO-DO 143-B, UNITED STATES, *Research on the developing of the atomic bomb. The New Mexico test experience*, 09/24/1945.

difficult scientific project. The report had a clear didactic purpose and explained the physical origin of this energy using simple animations. It also offered a brief summary of different moments during the research, the laboratories and the leading scientific figures.

The atomic bomb was presented to the audience for the first time as "*the most wonderful creation of science*."[4].

Its power was exaggerated, as was customary for NO-DO, declaring that: "*it is the energy generated by the heat of the sun and moves the Solar System*".

This news is very important historically, as it showed images of the Trinity detonation at Alamogordo on the night of July 16, 1945 for the first time.

The explosions at Hiroshima and Nagasaki were never once mentioned.

Therefore, this film document should be considered as a purely scientific news item.

Surprisingly, even at this time the possibility of using the 'atom' as a source of energy was already being mooted.

> "This heralds a new era in the use of energy that will cause a genuine revolution, NOT ONLY in terms of destruction, but also in many affirmative and constructive aspects, as well as the use of a new and gigantic driving force".

III. At last the bomb is deadly.

The third item of news from 1945 was the one that dealt with the bombings of Japan in detail. It's a very long report of nearly 3 minutes, published under the title "Japan ravaged".[5]

Four elements are highlighted in how the news is dealt with:

(I) The dead and wounded do not appear in the images. Only material destruction is shown, in which passing survivors are seen.

(II) There is no data on injuries or on the type of injuries or the future consequences radioactivity would have. Nor is there any data on the radius of the explosion, the level of destruction or its explosive power.

(III) It compares the destruction of Hiroshima and Nagasaki with the destruction of other cities as a result of conventional incendiary bombs. Through the images it is not possible to distinguish the different effects between the two types of technologies. When comparing images from Kura or Tokyo with Hiroshima, there is no way of distinguishing them.

(IV) The report states that "*these figures prove that Japan had been totally defeated before the atomic bombs were dropped*", thus implying that the atom bombs detonations on Japan were superfluous to their surrender.

It can therefore be said that the news defined the capacity for destruction but not the deadliness of atomic weapons. There is no blame or responsibility and science has completely disappeared from the discourse. The specific terminology is still to be established (kiloton or radioactivity are not even mentioned) and the consequences of the detonations are summarized in one word: "devastation".

IV. The weapon becomes a spectacle.

The fourth story is from 1946, in which the news covered the fifth atomic explosion detonated at Bikini Atoll (Marshall Islands, Pacific) in July 1946. The blast was covered by two NO-DO news reports: the first focusing on the preparations for the explosion[6] and the second on the blast itself.[7]

The first of these began with feedback from the Trinity explosion, from which the audience was transported to the preparations for the anticipated explosion at Bikini Atoll.

The three nuclear explosions prior to Bikini were a military and scientific secret (Trinity, Alamogordo, 1945) and two military operations (Little Boy and Fat Man, Japan, 1945) which were consequently narrated retrospectively. In contrast, the

[7] NO-DO 191-B, THE ATOMIC BOMB, *Sensational report at Bikini. The moment of the blast of and its results*, 09/02/1946.

explosion at Marshall Islands, although an event with very precise scientific and military objectives, was carefully planned to be broadcasted throughout the world. This, therefore, represents a turning point in the public handling of nuclear explosions.

The event, such as it was depicted by NO-DO, was a staging of the United States' atomic power in the purest of cinematographic styles. The world would attend a unique scientific experience, the first underwater nuclear explosion, with front row seats for what was probably the first public broadcast of a scientific experiment. Far from being a military, political and scientific secret, inherent in previous explosions, the entire world was invited to this one. In an elaborate propaganda manoeuvre, the US saw to it that the audience received the best, the most compelling, the most aesthetic and the most stimulating images available about the power of the atom.

However, this public experience had to be innocuous. It was a scenario free of collateral damage in which the immense power of atomic explosions could be contemplated unequivocally. No one would be shown in a bad light; there would be no wounded or dead, and no destroyed cities. Only the nature of an unknown Atoll hidden somewhere in the Pacific would be conveniently evicted by the power of the atom.

The showing of the preparations was an essential condition in the US programme. Hence, the first news report of the explosion was as important as the second report. It was shown how the population was evacuated, how king Judah of the Bikini inhabitants was informed about the bloodless explosion, and how the transfer of residents, in agreement with the decision of their king, was carried out. It was a premise that they knew that nothing but nature would be destroyed.

Yet, at the same time, it was essential that this manifestation of power was understood in all its magnitude. The numerous large vessels the US navy had in the blast area were used as a scale so that the images would let the power of the detonation be understood to everyone. It was a politically and militarily clean and safe experiment, but ambitious in terms of propaganda.

And it was a success. The images of the explosion are still used today as an expression of the power locked inside the atom. Those images became icons of the twentieth century. More so than those of the devastation of Japan.

It was an almost perfect propaganda manoeuvre. The dead forgotten, the enormity of the Bikini explosion remembered, a once anonymous place on earth eternally famous since the summer of 1946.

V. And the Soviets have the bomb.

After the Bikini Atoll explosion, no more news about atomic explosions was screened by NO-DO. In late 1949 a major event would change the strategic panorama of the world: the announcement of the first atomic explosion by the Soviets.

The coverage given to the global recognition of the first atomic detonation by the USSR was narrated in NO-DO with a brief news item put together with an evidently propagandist slant.[8]

Without the use of any images of the Soviet detonation, the front pages of newspapers served to create alarm among the population. Shots of the Soviet representative, Andrei Vichinsky, entering the UN completed the story. Despite the fact that this event marked the de facto beginning of the Cold War, nothing was explained to the Spanish people except: *"A scowling [Andrei Vichinski] gives an example of Soviet manners."*

The brevity of the information about the Soviet bomb is in our opinion a deliberate omission, as the newspapers filled pages with it. The report was supplemented, without interruption, with interventions at the UN by representatives of the US, Canada and the UK, urging the need for arms control and the control of nuclear material by the United Nations. Quite a show of political irony, since, until that moment, only these three countries, with different technical levels, had a say in the UN Security Council over the control of atomic energy, over which they kept a strict and absolute monopoly.

Whereas, the text of the newsreel clearly set out the future of the world: *"…doesn't wonder what happens now", a* sentence omitted by NO-DO in the Spanish version.

Finally, the security measures taken regarding the control of atomic secrets is maximised and the newsreel shows extreme dramatic footage of the various measures taken by the US to ensure complete control over their facilities. It is rather paradoxical that when the Soviets possessed the necessary technology to manufacture atomic weapons, the United States redoubled their security measures. Would it not have been wiser to have done so beforehand?

At least one mystery was cleared up: the anonymous enemy referred to in previous newsreels at last had a name: The Soviet Union.

VI. What's next?

---

[8] NO-DO 354-B, REFLECTIONS FROM THE WORLD, *The United Nations receives the news of the Soviets' first atomic blast. A report about this important international moment*, 10/17/1949.

The future of nuclear testing was glorious. It continued until it reached 205 detonations in 1963, when France joined in.

NO-DO made echo of many of these by showing a wide range of experiments and a variety of events related to nuclear explosions: explosions underground, at ground level, in military manoeuvres with models of houses and people to determine their effect, experiments with the US and British hydrogen bomb, atomic artillery, guided missiles with nuclear warheads…

Far from keeping things secret, the newsreel strove to publicize each and every one of the achievements in nuclear weapon material produced.

All this with a constantly repeated assertion: nuclear power is the guarantor of armed peace against an unidentified enemy. No detail or facts about enemy activity were ever offered by the newsreel. Their power and eagerness to launch a destructive mechanism, which curiously was not created by them, but by the nations converted into the guardians of world peace, is taken for granted.

PUBLIC OPINION STRIKES BACK: THE ITALIAN REFERENDUM ON NUCLEAR ENERGY

Matteo GERLINI
Università di Firenze, ITALY,
matteo.gerlini@unifi.it

Abstract

In its very beginning, nuclear power in Italy was well accepted by a bipartisan group of supporters among the political parties. Working on the historical archives of ENEL, the research reconstructs the shifting in the public opinion toward an antinuclear attitude, a shifting that brings the Italian state to reject all the nuclear plants on its territory. This happened through, the only case in the world, a popular referendum.
The paper investigates on the historical context for such public opinion stance, moving from the Italian Communist Party congress, in which an anti-nuclear motion was presented and got almost 50%. Two weeks after the congress, the Chernobyl accident happened. It raised a deep impression and a wide worry for the behaviour of the "Chernobyl cloud", and the public debate and polemic revived. Local and national demonstrations (Rome, 10 May) proliferated. The signature gathering for a national referendum began in July. In October, after a huge demonstration at Montalto di Castro, the Craxi government decided the stop to the yard, and called for a big Conference on Energy, which was held in February 1987 without any important result. The execution of the referendum, on 8-9 November 1987 stems from this background. On one side, the growing proposal of an Italian nuclear complex, and on the other side the bipartisan public opinion and political representatives opposing to the power plant. It is well known that in the referendum almost 80% of the votes were against nuclear. The legitimate question is: did this result univocally manifest the will of shutting down every nuclear power activity?

At the very beginning of the nuclear power era, Italy undertook a rapid development of nuclear programs, with the construction after the end of the Fifties of three nuclear power plants, entering into operation as early as 1964-65. By doing so, Italy was among the top nuclear countries in the world. Actually such a quick start did not reflect a coherent program that the Italian government was supposed to endorse.

It must be recalled that Italian scientific progress in the post-war period was damaged by both fascism and war destruction. Nevertheless, Italian progress in nuclear physics (the seminal experiment by Conversi-Pancini-Piccioni), after the fall of fascism and the end of the war, involved a development, by Edoardo Amaldi, of the fundamental work for reconstructing Italian physics through collaboration with the US research centres.

As early as 1946, a group of young physicists led a group of private industries to establish in Milan a research centre named *Centro Informazioni Studi Esperienze* (CISE, Centre Information, Studies, Experiences), with the aim of developing applied nuclear research and designing an Italian power reactor. The participation of Italy in NATO in 1949 opened the way to collaboration with the United States in this field.

In spite of the indifference of the Italian political community towards nuclear energy, in 1952 a State committee was established within the National Research Council (CNR), the *Comitato Nazionale per le Ricerche Nucleari* (CNRN, National Committee for Nuclear Researches), with the aim of promoting research, collaboration and applications of nuclear energy. However, the Committee was created without a specific law, it had no juridical state, and could not administer funding. Private industry strongly opposed a nuclear regulation, which arrived on the scene only in 1962. Actually, in 1952 CISE (who had initially opposed the birth of CNRN) proposed to CNRN's President, Francesco Giordani, a project for the construction of an Italian 1,000 kW natural uranium, heavy water, reactor, but this was not given serious consideration. Only later did Giordani advance the necessity for a higher power reactor, and CISE began the work for the project CiReNe (*CISE Reattore a Nebbia*, CISE "fog type" reactor). Moreover, Giordani initially opposed CISE's requirement for financing as it was a private institution, and when this aspect was resolved the funds were in any case insufficient.

In 1955, in the context of the Atoms for Peace campaign, the CNRN sent a commission to the US, which contracted the purchase of a 1,000 kW, CP-5 type reactor fuelled with 20% enriched uranium, which caused a conflict with the President of the private electrical society, Edison.

In subsequent years nuclear energy entered the Italian political debate, and raised growing interests in the energy industry. These developments were biased by the usual clash between private and public interests and programs. The events concerning CNRN revealed great relevance for the consequences that were to follow in later years (during the 1960s). In 1956 Giordani resigned, while Felice Ippolito assumed the role of General Chairman.

While the Euratom and the IAEA were established, in 1957, the debate on nuclear power also continued to grow in Italy. In the same year a bilateral agreement with the United States was signed, but its take-off was slowed by the lack of nuclear legislation in Italy, merging into the debate about the nationalisation of electricity.

In this period, the CP-5 reactor was purchased by CNRN: it entered into use in 1959, with a power of 5,000 kW and the name Ispra-1, at the newly established centre in Ispra. The centre of Ispra represented the Italian commitment to European efforts in developing nuclear energy on a supranational level. But this is another story.

Between 1956 and 1958 the contracts were signed for the purchase of three power nuclear plants: they were in fact three completely different reactors, but they led Italy in 1964 to the upper levels of electronuclear production in the world (the third one, following the US and the UK) In 1957 there were not yet any civil nuclear plants operating in the world (apart from Calder Hall in the UK), and the choice between different models was objectively very complex: it would be enough to recall that the choice of an enriched uranium reactor would have determined a strict dependence on the process of enriching-uranium.

In 1957 a transaction of the World Bank, BIRS, together with the Banca d'Italia, led to the establishment of the project ENSI (*Energia Nucleare Sud Italia*), which led to the purchase of a US reactor. The final choice (tutored by American, French, and British experts) was a 150 MW, BWR light water reactor from General Electric, which was built at Garigliano, Caserta, near Naples. It entered into operation in January 1964, but it was closed permanently following an accident fourteen years later.

In the meantime, as previously pointed out, at the end of 1955 the President of the private electrical utility Edison, Giorgio Valerio, had visited the US, looking for a contract for the purchase of a nuclear plant. This contract was delayed and, finally guaranteed by the American Export-Import Bank, and was signed only in 1957 with Westinghouse, for a 242 MW reactor. It entered into operation in October 1964 at Trino Vercellese, near Turin, Pedemont.

The third project was realized by public utility *Ente Nazionale Idrocarburi*, (ENI, National State-Company Hydro carbides), whose President, Enrico Mattei, had in 1956, created a specific entity (*AGIP-Nucleare*). Mattei's choice is important since, on the same line of gaining autonomy from the US enrichment industry, he chose a British "Magnox" reactor, fuelled with natural uranium and gas refrigerated. The plant was built in Latium near Latina; its total cost was 49 billion Italian Lire and in fact it was the first one to enter into operation, in May 1963.

Still lacking a comprehensive Nuclear Law, Italy passed a preliminary act regulating only some aspects of this matter in 1960. This Act was substantially limited to the attribution of a juridical status to CNRN, changing its name into CNEN (*Comitato Nazionale per l'Energia Nucleare*) and attributing it new tasks and responsibilities, financed with 80 billion Lire for the first five-year plan. CNEN had the responsibility for control and technical surveillance over all the nuclear plants, both in the construction and management stages, and of the implementation of tests. Ippolito was appointed Secretary General of CNEN, while its President was formally the Ministry of Industry.

* * *

The first centre-left government nationalized electric power, seizing its production from private companies: it was a turning point in the history of Italian energy production. It was instituted as *Ente Nazionale Energia Elettrica* (ENEL, National State-Company for Electric Power), a state owned utility for electric power. The parliament eventually approved the Nuclear Law in December 1962, which established that the production of nuclear energy is a prerogative of the State, or of societies with prevailing state participation. The second five-year plan had already been approved in October 1962, providing for the installation until 1970 of 1,000-1,500 MW with 2-4 nuclear plants.

Some months later, Ippolito was put on trial for administrative crimes. The affair split public opinion: many scientists (Edoardo Amaldi among them) defended Ippolito, while Giuseppe Saragat and his social-democratic party were accusative towards the maybe over-assertive CNEN leader. Ippolito was eventually condemned.

CNEN, in the eight years following Ippolito's trial, lost its *raison d'être*. ENEL took away all its prerogatives, and with the nationalization of electric energy it inherited from the private companies the three nuclear plants along with their technical staff. Even inside ENEL, besides in the country itself, there was an influential "oil party": but there was also a strong "nuclear party", reinforced by the Communist Party (PCI) and the Unions.

During the Seventies and the Eighties a series of National Energy Programs was proposed by different Governments, providing new programs for the construction of a large number of nuclear plants, while strong popular opposition and protests were growing in the country against these programs. Even a 30% participation by ENEL in the French fast-breeding reactor program started, with the national project of building a pilot reactor for testing the fuel bars (PEC, *Prova Elementi di Combustibile*), which had remained unfinished not only when the Italian nuclear programs were terminated, but would have been in great delay even with respect to the progress of the French program.

On the other hand, in any case, the second five-year plan had become outdated, since the models for nuclear plants were still in a process of being defined. The PCI direction engaged Ippolito's position, but it had no coherent program toward nuclear issues, as was the case with the majority of the political class. So the Italian Left were supporters of nuclear energy, and public opinion was generally well oriented toward a "Nuclear Italy".

When the idea of new nuclear plants returned, around the end of the decade, ENEL called for tenders, getting six offers, from American, British, and other European utilities. Finally an 840 MW BWR reactor form General Electric was chosen, which in fact was a somewhat hybrid model, a transitional model between small and big power plants. The construction of a new plant began at Caorso (Northern Italy) in 1970, led by the consortium ENEL-Ansaldo Nucleare-GETSCO: the works should have been finished by 1975, but suffered delays and increased costs; tests began in 1978, and the connection to the electrical grid was achieved in 1981.

During the Seventies and the Eighties a sequence of National Energy Programs were proposed by the different Governments, providing new programs for the construction of large numbers of nuclear plants, while strong popular oppositions and protests were growing in the country against these programs.

Although a law for the rearrangement of CNEN had been approved in 1971, its new role was delayed, so that it was ENEL that commissioned the Caorso plant, and in 1973-74 proposed four nuclear plants to be located in Central Italy, two in Latium (it would subsequently have been Montalto di Castro, see later) and two in Molise.

In 1975 CNEN submitted, and *Comitato Interministeriale per la Programmazione Economica* (CIPE, Interministry Committee for Economic Program) approved, a "*Piano Energetico Nazionale*" (PEN, National Energetic Plan), foreseeing different future scenarios of energy demand in Italy, and in respect of electric energy the installation in the period 1983-85 of a nuclear power of 13,000-19,000 MW, and further plants providing for a total nuclear power in 1990 of between 46,100 and 62,100 MW.

Possible locations had been preliminarily studied by ENEL, and were cemented by swiftly approved laws. Actually, these laws were based on the recently published American "Reactor Safety Study" (known as the "Rasmussen Report"), which suggested a safety zone around nuclear plants of a 16 km radius, successively confirmed by the Nuclear Regulatory Commission in 1978. In any case, the previsions of the PEN were recognized as being exaggerated.

In the meantime, ENEL got a 25% participation in the French gas diffusion enrichment plant Eurodif. Moreover, in 1976 a dubious project was elaborated of a second enrichment plant to be built in Italy, Coredif, fuelled by four nuclear plants of 1,000 MW each. (Four times the total installed nuclear power, including the not yet operative Caorso plant). Considering that France, for its military nuclear program, had a great need of plutonium and highly enriched uranium, nothing similar could be said to be necessary for Italy.

* * *

Also in 1976, a study of the environmental impact was presented in respect to the location of the aforementioned 2,000 MW nuclear plant at Montalto di Castro, which would lead to the authorization for its construction in 1979. In 1977 Donat Cattin, Ministry of Industry in the 3rd Andreotti cabinet, issued an ultimatum to the Regions in order to indicate potential sites for the construction of 20 nuclear plants. So the State gave the word to local public opinion, located close to possible nuclear sites, and this permitted a shifting of attitude in the public opinion as a whole.

Actually, in the meantime strong protests were growing, from the local populations, committees, environmentalist associations, some minority political forces, and even local administrations. If not the majority of the whole population living near the nuclear sites, but in any case a very visible part of that population took part in big demonstrations at Montalto di Castro, Viadana, Suzzara, San Benedetto Po (in Lombardy, when the location of nuclear plants was proposed there); the associations WWF and "Italia Nostra" also produced documents and organized meetings. The Lombardy Region appointed a Commission of study on nuclear plants, and requested advice from the *Istituto Superiore di Sanità*. A bipartisan front arose, based at the local level of the populations living near some plant sites.

However, the majority of the political forces and Unions were strongly in favour of nuclear energy, including the majority of the Communist Party and the left-wing Union CGIL. In any case, in response to these movements the political debate grew: the Commission of Industry of the Parliament held a fact-finding inquiry, and there was a Parliamentary debate.

However, a second PEN was approved by CIPE in December 1977, providing for the immediate construction of 12-13 nuclear plants, leaving the remaining 8 for after 1985. In response to this, the popular protests and demonstrations continued to grow. Even more so when Romano Prodi, Industry Minister in the 4th Andreotti cabinet, authorized on 19th February 1979 the construction of the plant in Montalto di Castro: just before the Three Mile Island accident, on 28th March 1979. During the same days the movie *The China Syndrome*, with Jane Fonda, came out. In the meanwhile, in August 1978, the Garigliano plant had been shut down after several accidents.

In the USA, following the Three Mile Island accident, two commissions were appointed (headed respectively by Keenly and Regain), which invited nuclear utilities to radically change their safety regulations, and proposed to authorize nuclear plants far from residential areas, to provide emergency plans approved by a Federal agency for safety, and to provide for the evacuation of population in case of accidents to a radius of 30-40 km.

In Italy, on the institutional side, in June 1979 the results of a fact-finding special ecological commission from the Senate gathered a majority of favourable opinions, with the exception of the ecological associations WWF and "Italia Nostra". In December the new Minister of Industry, Antonio Bisaglia, appointed a Committee on nuclear safety, which approved a document with the relevant opposition, and a minority report, from the three environmentalist representatives, denouncing the deficiency of the Italian safety rules with respect to the international ones. The PEN was successively revised in 1980 and 1981, providing for the construction of nuclear plants of at least 6,000 MW (indicating potential sites in the Regions of Piedmont, Lombardy, Veneto, Tuscany, Campania, Puglia, and Sicily), with a *Nuclear Unified Plan* (PUN) based on the PWR Westinghouse reactor (note the contradiction with the previous choice of the BWR Caorso plant from General Electric). Also note that in these same years Italy had to reduce from 25 to 16,5% its participation in the Eurodif enrichment plant, and was obliged to undersell a part of the enriched uranium it had already acquired, following a down-sizing of its nuclear ambitions.

In the meantime, in 1982 CNEN acquired the new name ENEA (*Ente Nazionale per l'Energia Nucleare e le Energie Alternative*), with a few changes, but with a new research section on renewable energies: a preferred choice, since the new 1985 PEN confirmed 12,000 MW of nuclear energy.

In the years 1981-1983 the opposition against nuclear energy grew further. Several municipalities expressed their opposition. A law in 1983 provided for economic incentives to those municipalities which had accepted nuclear and thermoelectric plants on their territory (besides nuclear power, also coal fuelled plants were pushed by the various PENs).

ENEA expressed its positive opinion for the suitability of the sites of Viadana and San Benedetto Po, and ENEL begun the geological tests. Anti-nuclear demonstrations, violent clashes with the police, and arrests followed. Two municipal popular referendums were held in Viadana (1984) and in San Benedetto Po (1985) and opposition to the nuclear plants won out in both cases. In 1985 there was a big demonstration in Rome.

It must be recalled that the anti-nuclear movement was reinforced by the "Euromissiles" crisis (the "Atomic Clock" of the Bulletin of the Atomic Scientists was put at barely 3 minutes from Midnight. The debate on a "nuclear winter" grew, and the movie *The Day After* made a strong impression on the public), along with opposition to the deployment of Cruise missiles in Comiso, Sicily.

* * *

And so we arrive at the penultimate act, only 36 days before the Chernobyl accident. On 20 March 1986 the CIPE approved the 4th PEN, providing only for the construction of the 2,000 MW plant at Montalto di Castro, plus 2,000 MW more at Trino Vercellese, in Piedmont (never begun), and the localization until 1986 of two more 2,000 MW plants each, respectively in Lombardy and Puglia; in addition it provided the acquisition of 400 MW from the 1.2000 MW fast reactor *Superphénix* under construction in France, an ill-fated project.

In April 1986 the PCI held its XVII congress, in which an anti-nuclear motion was presented and attracted many votes. Two weeks later, on 26 April 1986 the Chernobyl accident happened. It made a deep impression amidst great concerns for the behaviour of the "Chernobyl cloud", and the public debate and polemic was thus revived. Local and national demonstrations (Rome, 10 May) proliferated. In July the signatures gathering for a national referendum began. In October, after a huge demonstration at Montalto di Castro, Bettino Craxi's (Italian Socialist Party) cabinet decided to halt the process, and called for a major Conference on Energy, which was held in February 1987, without any significant result.

The execution of the referendum, on 8-9 November 1987, was the prologue to the termination of Italian nuclear power. It is well known that in the referendum almost 80% of the votes were against a nuclear program. The legitimate question is: did this result univocally impose the closure of every activity related to nuclear power? The popular will in this sense was quite evident (though the Chernobyl accident undoubtedly played a role). The problem is that Italian law formally allows only for "abolitionist" referendums, concerning specific existing laws or regulations. So that the referendum abrogated: (1) the prerogative of CIPE to decide on the location of nuclear plants, when the interested municipalities were not able to decide; (2) the compensation available for municipalities which hosted nuclear or coal plants; and (3) the possibility for ENEL to participate in international nuclear programs (in this case, *Superphénix*).

At this point the last act intervened. In the aftermath of the referendum the Government of Giovanni Goria (the first Christian-Democratic) suspended the project of the Trino plant, cancelled the Latina plant, and started verifications on the safety of the Caorso plant and the feasibility of the Montalto di Castro plant under construction (for the non-nuclear parts).

In subsequent years all the Italian nuclear plants were closed (they still await decommissioning, and they will no doubt wait a very long time, whilst the majority of the fuel elements are still in the deactivation pools, often under precarious conditions). Furthermore, almost every activity in the field of nuclear energy has been terminated, specialists and agencies having been transferred to other fields.

GENDER STANDARDS IN DRUGS HISTORY: CROSSING BOUNDARIES

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 892.

HORMONAL CONTRACEPTION, GENDER AND SOCIETY IN SPAIN (1966-1979)

Abstract

Social studies focusing on women's health, women's history and/or medicine for women are not always elaborated using gender as a category of analysis. In the last twenty years in Spain, many scholars have made important contributions on contraception focusing on demographic, political or ethical aspects, but few of them have discussed their results from a gender perspective. These studies usually do not include woman's medical, scientific, social and religious definitions; the role of women as doctors, health administrators, scientific researchers, and/or health activists; the contribution of women's and social movements to the improvement of women's life conditions; the relations between sanitary and women's movements, the construction of collective gender identities, the experience of real women in accessing and using oral contraceptives and so on.
In Spain, during the last years of the Franco dictatorship and the democratic transition (1970-1982) there was a widespread movement towards the legalisation of contraception, prohibited since 1941. In this paper we want to look at the discourses surrounding the legalization of the pill as represented in the press, and at the role played by the feminist movement and the medical professionals in this debate. For this purpose we analyse, on the one hand, the information on the hormonal contraceptives that was published in the Spanish general press, feminine magazines and different kinds of feminists' publications during the 1970s, as well as in the main gynaecology handbooks used in Spanish faculties of medicine during this period. On the other hand, we will use oral interviews with health professionals and feminist activists.

Introduction: intersectional approach in the historiography of oral contraceptives

Numerous works on the history of oral contraceptives have been published during the last two decades. These studies include a spectrum of topics ranging from, among others, the first contraceptive pill, contraceptive implants, to injections and emergency contraceptives. Many of these works apply intersectionality as a tool for in-depth analysis of the relationship between categories such as gender, class and ethnicity in the processes of the design, production and commercialization of contraceptive drugs. Gender as a category of analysis has also been adopted by some contemporary historians and sociologists interested in psychotropic drugs (Metzl 2003; Tone 2007; Romo Avilés, Gil García 2006).

An intersectional perspective is considered to be one of the most important theoretic contributions of women's studies (McCall 2005, 1771). For the social history of drugs, intersectionality has become a useful concept to analyze with more precision and complexity the process of circulation of drugs in its social and scientific context. Intersectionality also helps situate the analysis in the cultural, economic and ideological diversity of women who produce, publicize, consume, or reject drugs, thus, providing the medication with a new symbolic content which goes beyond its pharmacological properties.

An intersectional perspective makes it possible to study, following the proposal made at the end of the 1980s by the historian Linda Gordon, how different collectives and people can simultaneously be agents and victims, and discriminate and be discriminated against (Gordon 1988). Intersectionality also makes it possible to analyze the role of pharmaceutical technologies within the context of gender, race, ethnicity and class hierarchies. Lara Marks and Elisabeth S. Watkins, the first scholars who published on the history of the contraceptive pill from a gender perspective (Marks, 2001b; Watkins 1998), have been followed during the last two decades by authors who incorporate categories of race, ethnicity and class into their studies of the processes of producing and testing drugs. These works focus on different responses to contraceptive and reproductive technologies among women of different races, ethnicities and classes, and the possible uses of these technologies by state institutions and agencies providing family planning, as well as the benefits and social problems these practices generate (Grant 1993; Ross 1998; Roberts 1997; Rodrique 1998; Nelson 2003; Solinger 2005; Schoen 2005). They also study issues such as abortion, sterilization, oral contraception and single parenthood from the particular perspective of African American women and analyze the practices of resistance used against the institutional attempts to impose certain contraceptive methods on women of colour, such as sterilization or hormonal implant. These works are limited to US or British contexts, where there has been a more articulated academic interest in the ways in which categories of gender, race and class have closely interacted during the past two centuries. Other authors focus on Puerto Rican women and discuss, among other topics, their participation in the late 1950s in large scale clinical trials of Enovid, the first oral contraceptive commercialized in the US (Briggs 2002; López 2008).

Using gender, race, ethnicity and class as categories of analysis does not necessarily guarantee avoiding victimization. Some recently published works, especially those by Roberts (1997), Briggs (2002) or López (2008) focus more on women as subjects of racist and sexist discrimination rather than on examples of their agency. Furthermore, these authors do not give sufficient space to the practices of using different contraceptive technologies as possible strategies of resistance and empowerment.

The pill in the Spanish press: aims and methodology

In 1960, when the first contraceptive pill was commercialised in the United States, all contraceptive methods were prohibited in Spain. From January 1941, six months after the victory of Franco's army over the republican state, until 1978 there existed a law for "the protection of natality, against abortion and contraceptionist propaganda" (Federació Local de Sindicats de Barcelona 2008), which prohibited the sale and publicity of any contraceptive methods.

Nevertheless, the pill started to circulate in Spain in 1964. A year later, a new law would broaden the variety of drugs that could be used by doctors, including hormonal drugs. Prescribing the pill became possible but was limited to cases of gynaecological disorders (Ministerio de Gobernación 1965; Jones 1977). The commercialisation of the contraceptive pill and the publication of the encyclical *Humanae Vitae* in 1968 generated ten years of great interest and lively debate on contraception that culminated with the legalization of contraceptives in late 1978 in large part due to a successful struggle from the feminist movement.

In Spain, as far as we know, intersectionality has never been applied to the study of the history of the contraceptive pill. Specific academic production on the history of hormonal contraceptives is limited to an unpublished thesis that focuses mainly on ethical aspects and lacks any gender perspective (Sánchez Carazo 1998). Moreover, in Spain during the 1960s and 1970s, an intersectional analysis was confined to categories of gender and class, considering that ethnic diversity was practically limited to gypsy collectives. Including ethnicity is beyond the scope of this paper, although we do not exclude it from our further studies.

In this paper we look at the debates surrounding the circulation and legalization of the pill in the 1960s and 1970s in Spain, a period that comprises the last fifteen years of Francoism and the beginnings of Spanish democracy, by using gender as a category of analysis. We pay attention to the actors and discourses that appeared in the daily press, medical press and feminist press. We review two of the oldest Spanish daily newspapers: *La Vanguardia,* a liberal newspaper published in Barcelona, and *ABC,* a conservative newspaper published in Madrid. We also review six years of *Tribuna Médica* (Madrid, years 1964-1969), the most prominent general Spanish medical journal during the 1960s and the 1970s, and *Vindicación Feminista* (Barcelona), the first feminist magazine to be published in Spain from 1976 to 1979.

The pill in the daily press

The dominant participants in the debate on hormonal contraception in both newspapers are foreign and Spanish physicians. Among the Spanish experts, the two most prominent figures seemed to be Professor Botella Llusía and Dr. Ángel Sopeña Ibañez. Each of them exhibited a different position; whereas Professor Botella Llusía was quite conservative, Dr. Ángel Sopeña Ibañez seemed to be more open and favourable to contraception. Botella Llusiá (1912-2002), cited in the late 1960s and 1970s, was a professor of gynaecology and obstetrics at the Complutense University of Madrid. He was author of numerous publications on gynaecology, sterility, gynaecologic endocrinology and oral contraceptives, and founded the most important school of gynaecology in Francoist Spain (Díaz Rubio 2003, 28-29). Ángel Sopeña Ibáñez (1913-1991) was consulted more frequently in the second half of the 1970s, when he was a professor of gynaecology at Complutense University in Madrid. He was a member of the Spanish Communist Party, and collaborated with the feminist family planning movement in the Spanish capital (Ortiz and Ignaciuk 2010). The debate on the pill was not limited only to gynaecologists and obstetricians, but other medical specialists, including dermatologists and psychiatrists, also participated.

Another category of experts whose opinions were frequently presented was that of Catholic priests, who appeared in all the important articles or multi-expert debates on the pill in which they stated their opposition to the pill as something unnatural and unacceptable within a Catholic marriage. This opinion was well represented in both newspapers. However, some priests exhibited a more moderate point of view, and even questioned the legitimacy of the church to participate in the debate on contraception. Still other priests defended sexuality as one of the pillars of a Catholic marriage, and criticized the rhythm (or Ogino) method as psychologically destructive (Ortiz and Ignaciuk, in press).

The most striking fact in the debate on the pill in the reviewed press is the nearly complete absence of voices from women and feminists. The few women who did talk about the pill were conservative or sceptical for religious and medical reasons. In 1975 –the year of Francos's death– *ABC* offered a breakthrough, as female journalists started to write about controversial issues related to women, such as single motherhood, or later on, family planning and female sexuality. In *La Vanguardia*, the feminist movement's fight for legalization of contraceptives received some, but rather unfavourable, attention in the late 1970s (Castillo García 2010).

The vast majority of the articles and news items published in both daily newspapers were dedicated to the side-effects of the pill (Ortiz and Ignaciuk, in press). This is similar to the media coverage in Britain and the United States in the late 1960s and 1970s, when the initial emphasis on the socially liberating effects of the pill was replaced by a more careful examination of the risks related to its consumption (Junod 2007). As historians of the contraceptive pill indicate, the potential health hazards related to the pill had to be carefully evaluated from its earliest stage of commercialization, considering that the pill was being used by healthy women to prevent pregnancy (Junod and Marks 2002, 120). The scientific debate on the side effects of the pill was long and confusing, along with its representation in the media, which often published contradictory information about its safety.

The first known side effects of the pill such as nausea, breast tenderness, weight gain and breakthrough bleeding were reported during the first large-scale clinical trials performed on women in Puerto Rico, Haiti, Mexico, Hong Kong, Australia, Ceylon or Japan (Marks 2001b, 96-106). These side effects, considered similar to those experienced during early pregnancy and/or menstruation, were underestimated by researchers and medical professionals as minor and temporary (Watkins 1998, 77), and also were often represented in a similar manner on various occasions in *ABC*. Lara Marks (2001a, 219) and Elizabeth Watkins (1998, 79) pointed out that the evaluation of these side effects was generally dependent on the concept of pregnancy, either as a natural or as a potentially hazardous condition for women.

The side effect of the pill that received the most coverage in the reviewed newspapers was thrombosis. The news reporting was confusing and contradictory, and there was a constant interchange of articles that either underlined the risks or reassured the public of the pill's safety. In the 1970s, the concern about the potential relationship between the pill and cancer began to appear. These articles expressed opinions both for and against the carcinogenity of the pill, and cited both national and international experts to support their positions.

Another important aspect of the medical debate on side effects of the pill, as represented in the daily press, was the repeated plea that women should take the pill under medical surveillance. Medical experts often quoted in *ABC* referred to the need for medical control concerning the use of oral contraceptives. This opinion seemed to reflect a need to maintain the privileged position of doctors in relation to their female patients. This hierarchal relation was being challenged at that very moment by feminist activists and feminist doctors working in the first family planning centres established in Madrid and Barcelona (Ortiz and Ignaciuk 2010).

The pill in the medical press

The scarce amount of information published in *Tribuna Médica*, the most widespread Spanish professional medical journal in the late sixties, seems to indicate, first, that the pill was not a great concern for medical professionals and, second, that the main opinions being expressed about the pill were the same voices as those in the general press: medical doctors and priests. Despite the fact that doctors could legally prescribe hormonal drugs, including the pill –even if not explicitly for its contraceptive properties–, since 1965, very little attention was paid to oral contraception in *Tribuna Médica*. The editors of the magazine were generally indifferent to the pill, and when discussed, it was in the broader context of population concerns or according to the official position of the Catholic Church.

During the years of 1964 to 1969 only two references to the pill were published. In May 1967, within the context of a report about a conference organized by the Association of Medical Writers [*Asociación de Escritores Médicos*] on social, legal and ethical aspects of population growth. The authors (a sociologist, a lawyer, and two priests) discussed overpopulation in terms of "responsible parenthood" as defined by Paul VI, or reproduction as "the most basic natural function" of the human kind. None of them mentioned oral contraceptives as a possible solution to the "population problem." This is very similar to the medical discourse published in *La Vanguardia* during the early 1970s in which the pill was often depicted as a threat to the survival of the human kind (Castillo 2010, 92).

The medical version of the topic was given by Professor Botella Llusiá, which displayed a more technical approach than did his contributions to the general press. He described the pharmacological action of the oral contraceptives available in the Spanish market at the time, and established a clear division between sequential, mixed and progesterone-only contraceptives. For moral reasons the author considered the use of the progesterone-only pills unacceptable since they stopped the implementation of the blastocyst in the uterine wall, which he considered to be the same as inducing an abortion (Adroer 1967).

A more explicit mention of the pill appeared in a letter to the editors of *Tribuna Médica* by a paediatrician (Javier Oroz 1967), where he discussed the co-existence of doctors for and against oral contraceptives in his medical speciality.

The pill in the feminist press

As stated above, women's voices concerning the use of the contraceptive pill were practically absent from the daily and medical press that we analyzed until the late 1970s. Only then did articles on the pill authored by women start to appear in *ABC* and *La Vanguardia* following the wave of liberalization and the growing impact of the feminist movement. Nevertheless, the dominant role of the male medical expert remained undisputable. However, female journalists and activists used alternative media spaces to discuss their opinions and preoccupations related to family planning, such as the newly created liberal daily *El País*, some magazines published during the period of democratic transition (*Triunfo*, *Cambio 16*) and the first feminist magazine, *Vindicación Feminista*. Founded in 1976 by Lidia Falcón (born 1937), a feminist philosopher and lawyer. She became one of the key figures of radical feminism in Spain during the transition to democracy (Larumbe 2009, 23). The magazine's ambition was to construct a plural and autonomous space for the Spanish women's movement. *Vindicación Feminista* was published in Barcelona from July 1976 to December 1979, and all the articles that appeared in the magazine were authored by feminist journalists.

The pill did not appear in *Vindicación Feminista* as an issue of concern on its own, though the pill was discussed within the broader debate on the legalization of contraceptives and abortion. The eleven articles that mentioned the pill also spoke about abortion, contraception and family planning. In contrast, there were eight articles that focused solely on the issue of abortion in Spain. When discussed, oral contraceptives were presented as the most widely used contraceptive method by middle class, educated women, who were able to get the pill from private gynaecologists as a therapeutic drug, not as a contraceptive. This semi-legal way of obtaining the pill was criticised since it was out of reach for women from marginalised neighbourhoods and regions, who did not have easy access to doctors (Begoña 1977). While accessibility to the pill was considered a class privilege, it also appeared to be the only available method in Spain used by women who should have been discouraged to do so for health reasons. It is worth noting that general newspapers like *ABC* or *La Vanguardia* expressed the opinions of priests and male doctors, while alternatively *Vindicación Feminista,* being a feminist magazine, cited mostly women's opinions on the pill, both as consumers and as feminist activists. These women often questioned and problematized the role of doctors and the hierarchy of the Catholic Church in their debates on oral contraceptives. They discussed issues such as doctors' reluctance to prescribe contraceptives, the internal disagreements within the Church following the publication on the encyclical *Humanae Vitae* (Larrauru 1977, 3), and the efforts of certain priests to prevent women from using the pill (Begoña 1977).

Vindicación Feminista gave much importance to the negative discourses and attitudes towards the pill. Side-effects were strongly emphasised (Encuesta 1979), sometimes with the support of the authority of doctors, such as José Badía Serra, from the Department of Gynaecology and Obstetrics of Sant Pau Hospital in Barcelona (Falcón 1978). The consumption of oral contraceptives was considered as a form of excessive medicalization of the female body (Taboada 1978). Only one author considered the bias and negative representation of the pill in the media (Belaguer 1977).

Conclusions

The presence of numerous publications concerning the contraceptive pill in the Spanish daily press during the time that it was illegal proves beyond a doubt the existence of a public debate on oral contraception in this country as early as the late 1960s. During the initial period of democratic transition there was a great increase in the number of publications that reflected the political climate of the time. The frequent references to British, American, and, to a lesser extent, French and Italian studies and practices suggest the presence of a vivid interest in the international debate on the pill, and especially its safety, which constituted the main argument in the debate represented in *ABC* and *La Vanguardia*. The debate on oral contraceptives in the reviewed daily press was dominated by the concern of side effects with doctors being the primary experts. The religious and moral discourses were also present, especially in relation to the encyclical *Humanae Vitae*, but they were neither dominant nor homogenous. In *Tribuna Medica*, there was scarce coverage on oral contraceptives in the late 1960s, and articles that were published did not differ from what appeared in the contemporary daily press. In contrast, the feminist press focused on issues that were not reflected in daily or medical press, such as access to other possibilities for women from different socio-economic backgrounds, or the pill being the only contraceptive choice available. By the late 1970s *Vindicación Feminista* openly criticized both the pill and the medicalization of contraception on the female body.

(UN-)SAFE DOSE LEVELS. SCIENTIFIC-FEMINIST COALITIONS AND CONTRADICTIONS IN WEST GERMANY IN THE 1950S AND 60S

Heiko STOFF
Department for the History of Science and Pharmacy,
Technische Universität Braunschweig, GERMANY
h.stoff@tu-bs.de

Abstract

This contribution deals with the different and varying agendas concerning policies of zero tolerance for chemicals invading the gendered human body in post-war West Germany. The main focus thereby is on scientific-feminist coalitions and contradictions in regard to two very different chemical substances –estrogens and butter yellow.

Estrogens

In the 1930s the just-standardized estrogens combined the function of physiologically active agents in a chemically regulated mostly female body with industrial produced and clinical tested measures of intervention into this body, like the mere biopolitical treatment of sterility and the mere clinical treatment of menstrual or climacteric complaints. In both regards they were defined as highly effective molecular substances, thereby creating a new ontology of the female body as well as new commodity and tool for the optimization of female functions. Its existence could be proved through the experimental production of deficiency and its suspension: the removal of the ovaries; the recovery of specific functions through organo- and hormonal therapy.[1]

The increasing demand for sex hormones was satisfied by the leading pharmaceutical companies. While testosterone and progesterone could be synthesized in the 1930s, the biochemists did not succeed in the synthesis of estrogens (ethinylestradiol) until the late 1940s. The only alternative to estrogens isolated from pregnant mare urine, which the Berlin *Schering AG* distributed under the name of *Progynon*, was the stilben derivate diethylstilbesterol (DES), which in 1938 Charles Dodds produced as an estrogen-active compound.[2] In the course of the 1930s a new (hormonal) physiology of

---

[2] Dodds, Goldberg, Lawson, Robinson, 1938. Gaudillière, 2008, p. 117 and Gaudillière, 2004, pp. 220-221.

the improvable gendered body was set into clinical and medical practice.[3] But a dark cloud overshadowed this success story of industrial-clinical-scientific cooperation. Biologically active substances like hormones and vitamins were not only acclaimed as a cure for all, but exactly because of their effectiveness to induce growth, they were also suspected to be toxic or even cancerogenous. While this concerned nearly all hormones and vitamins, estrogens addressed a particular threat.

In 1915, the Japanese pathologists Katsusaburo Yamagiwa and Koichi Ichikawa painted rabbit ears with coal tar thereby inducing skin cancer. A working group around Ernest L. Kennaway and James W. Cook blamed the pure chemical compound benzpyrene (present in coal tar) to cause the cancerogenous effect. Therefore, in the 1920s aromatic hydrocarbons were regarded as extremely carcinogenic substances. One of these aromatic hydrocarbons, methylcholanthrene, was related to steroids. It was even possible, as the leading chemists Heinrich Otto Wieland and Adolf Windaus independently of each other showed, to convert cholesterol and bile acid into methylcholanthrene. Therefore wasn't it possible, that under certain circumstances steroids also could turn into methylcholanthrene? Because estrogens were characterized by a partially aromatized hydrocarbon framework, these useful biopolitical agents were suddenly in the critical and not therapeutical focus of cancer research.[4]

Adolf Butenandt, Germany's leading biochemist of the 1930s, director of the *Kaiser-Wilhelm-Institute for Biochemistry* in Berlin-Dahlem, who, in close cooperation with the *Schering AG* had isolated estrone, was indeed shocked, that this thesis seemed to gain facticity in some scientific writings. There was an achievement at stake which was of high importance for Butenandt's own career, for everyday gynaecological practice, for the biopolitical interests of the national socialist state, and finally and most of all for Schering. In the summer of 1937 Butenandt, financed by the *German Research Foundation* and in cooperation with the gynaecologist Carl Kaufmann from the *Charité* in Berlin, organized a working group to prove this suspicion.

The story of this research project which combined the interests of laboratory science, clinic and industry has been written at length by the French science historian Jean-Paul Gaudillière.[5] The expectations were surely to give estrogens the benefit of the doubt, but Butenandt was a respectable scientist, who never would have faked his findings. What Kaufmann and Butenandt did was to concentrate their research on the question of genetic precondition. Kaufmann, who in the 1930s had tested *Schering*'s hormone products for optimal dosages and broader indications (he was an expert on the treatment of amenorrhoea, the lack of menstrual periods), administered three thousand mice with estrogens. He concluded that even a continuous administration wouldn't increase the rate of tumours. Butenandt again referred back to the experimental work done by Antoine Lacassagne, who had injected follicle hormones to male mice, thereby inducing breast cancer. Sex steroids, Butenandt stated, affected genetic preconditions which existed only in certain mice breeds. Estrogens were only the causer, but not the cause of cancer; the genetic precondition was the necessary condition for the hormonal effect. When Butenandt presented the results of the working group in June 1940 he summoned that estrogens just like DES could indeed induce breast cancer with genetically preconditioned mice, but that this had nothing to do with its chemical structure. Schering wasn't very pleased with this statement, because it gave DES, which the competitor *IG Farben* produced under the brand name of *Cyren*, the same status as *Progynon*. Anyway, soon after this they settled an agreement: that *IG Farben* would stop to compare its cheaper product to *Progynon*, while *Schering* would be quiet about the toxicity of *Cyren*. But what remained as a fact was the experimental testimony, that estrogens themselves were not a cancerogenous substance.[6]

The actors involved were merely scientists, clinicians and the pharmaceutical industry. But where were the persons concerned, where were the women? Now this took place in Nazi Germany, so there were limits to dissent. But as I will show next, this wasn't true for another debate on other cancerogenous substances. I will propose two assumptions to explain the silence of women and women's organizations: 1. the reproductive and biopolitical issue was part of the feminist discourse in the first decades of the 20th century. There was simply no interest to criticize hormonal therapy; 2. medical topics were negotiated between the mostly male experts. In the first half of the 20th century a very hierarchical relationship existed between doctors and patients, which left no space for any objection by the side of the patient.[7]

Butter yellow

In the early 1930s the use of food additives like bleaching agents, colorants and preservatives were related to a statistically presumed rise in cancer. A critique of modern food production was common in all western nations since the last third of the 19th century. But while this critique was focussed on food fraud, in Germany the highly influential interplay of diet reform (as part of the life reform movement) and new dietetics emphasized the need for a healthy diet based on natural and

pure food. In the 1930s diet-reform advocates like Werner Kollath, the German guru of wholefood nutrition, denounced industrially produced food as denaturalized and dangerous for the health of the people. In 1931 Curt Lenzner published a book entitled *Gift in der Nahrung* (*Poisoned food*). One year later Erwin Liek, the notorious enemy of the social and health security system of the Weimar Republic, finally proclaimed a connection between civilization and cancer, actualized in chemicalized and technicalized food.[8] This strong position gained even more strength with the empowerment of the National Socialists, its narrative of a pure body threatened by foreign matter fitted well into Nazi ideology. In the late 1930s and early 1940s there were inner contradictions and an open dispute between diet reformers and those nutrition experts who had to fulfil the need of belligerent Nazi Germany to secure the nutritional situation with the help of canned or frozen food in particular and food technology in general.[9]

Around 1940 the case of butter yellow, an azo compound used to give butter an attractive yellow colour, caused international stir. Between 1932 and 1937, the Japanese pathologist Riojun Kinosita proved that several azo dyes, most prominently and widely used butter yellow, were cancerogenous. The German pharmacologist Hermann Druckrey confirmed these results.[10] Therefore, in June 1939 the *International Congress for Cancer Research* recommended the ban of butter yellow for food colouring. Only a few months later Hans Reiter, the president of the *German Reich Health Office*, suggested a new *German colour law* (*Neues Deutsches Farbstoffgesetz*). Robert Proctor in his book on the history of cancer research in Nazi Germany outlined the complicated situation Reiter was in, because a sudden removal of colours in the middle of the war might have been interpreted as the application of inferior foodstuffs. But on the other hand there were already rumours that coloured food might be dangerous for health. And at this point, the women's organizations of Nazi Germany interfered, applied pressure to Reiter and finally succeeded. As Proctor tells this story, in 1941 a member of Göttingen's so called *NS-Frauenwerk* asked her superiors why "cancer-causing" substances were still allowed in butter and margarine. The regional women's leader informed Reiter that (quote) while women were certainly willing to sacrifice for the war, accepting the presence of cancer-causing agents in food was something else. And indeed Reiter, who appreciated the housewife's organization as allies in his efforts for wartime food security, rather successfully negotiated with the different groups producing and marketing coal tar dyes to reduce the use of dyes. Finally, even the almighty *IG Farben* stopped the production of butter yellow.[11]

To sum this story up, it was a coalition of scientists, politicians and women's organizations who succeeded in the prohibition of butter yellow. Women organizations, as has been shown in several studies, were deeply involved in Nazi Germany's health and nutrition policies. Housewives thereby were explicitly defined as consumers and guardians of nature. They were far from being marginalized and were able to determine health political decisions. They were worried by poisoned food but not by cancerogenous hormones.

Estrogens and butter yellow

In the 1950s and 60s these two stories of silent and worried, of apolitical and political women convened. It was indeed Butenandt, the defender of estrogens, who in 1948 frightened the public when he proclaimed that cancerogenous butter yellow was still in use.[12] Even if this accusation was immediately denied by nutrition experts and representatives of the pharmaceutical industry a debate was opened, which shaped the policies on food additives in Germany throughout the 1950s. It was the well respected physician Karl-Heinrich Bauer who introduced a new oncologist theory, neglecting the role of genetics for cancer while emphasizing the significance of exogenous agents like rays or chemical compounds. Bauer based this assumption on the case of azo dyes, but he also recapitulated the thesis of a strong connection of civilization and an assumed rise in cancer.[13] These mere speculations gained scientific facticity through the collaboration of Druckrey with the mathematician Karl Küpfmüller in 1948: Druckrey conducted animal tests with butter yellow. These experiments showed that to produce tumours, a certain total dose is necessary, regardless of how it is distributed between 35 and 365 days. The latency period, Druckrey stated, is inversely related to the daily dose. If experiments are extended over the life span of the animals, a smaller dose is necessary to produce an effect: with increasing age, there is increasing disposition to develop tumours. And as Druckrey concluded: "The carcinogenic effect of butter yellow was thus, even at the smallest doses, irreversible from the beginning of the experiment during the entire life span of the animals, and is additive with further exposure without any modification, until, after a critical total dose has been exceed, the tumours develop". Because of the

latency period –the dose-effect and dose-time relation– it was nearly impossible to decide whether a certain substance is cancerogenous or not. From then on it was chemical substances in everyday use that showed the most risk.[14]

Bauer, Druckrey and also Butenandt were comrades in arm in the ongoing war against cancer. The field for this battle was the senate commissions for preservatives, foreign matter and colorants established by the *German Research Foundation*, in which representatives of the pharmaceutical and food stuff producing industry and politicians under the guidance of scientists negotiated the use of food additives.[15] While the commissions worked behind closed doors, a public discourse about the "toxic condition" of modern life and the negative role of the pharmaceutical and chemical industry gained strength. The catchphrase of a "toxische Gesamsituation" ("toxic total situation"), coined by Fritz Eichholtz, director of the Pharmacological Institute at the University of Heidelberg, thereby instructed a far-reaching debate on the boundaries of risk assessment and the dangers of chemical substances.[16]

But already in the early 1950s there was an open critique that consumers were not represented by the commissions. At this time there were indeed no consumers' associations existing. But housewife's and women's organizations resumed their battle against poisoned food. In February 1950 the *Deutsche Frauenring* (*German Women's Association*) demanded measures against the colouring of food. Other catholic or protestant women's and housewife's organizations wrote letters to the ministry of health and of the interior to prohibit food colouring. The Information service for women's question, uniting eighty women's organizations and groups, applied to all relevant political representatives to claim the passage of a new food law based on a white list of experimentally proven substances.[17] On February 24th, 1956 the members of parliament Hedwig Jochmus (CDU), Käte Strobel (SPD), Marie-Elisabeth Lüders (FDP) and 43 other female delegates of the German Bundestag presented an application, that the Bundestag should request the Federal Government to produce a draft for a new food law until May 1st, 1956. This proceeding was well prepared by Jochmus, Strobel and Werner Gabel, undersecretary in the ministry of the interior. While there was a lot of laughter by the male members of parliament about this issue, the „Einheitsfront der weiblichen Abgeordneten" ("unity front of female delegates") found strong response by the public.[18] The women's organizations succeeded in releasing a new and much stricter food law. But the consumer's organizations which were established right in the context of this debate were soon to be masculinized. As well as the food law, which based on Druckrey's dose-time-effect-law was successively abolished by specific regulations, which again based on the much more industrial friendly concept of an acceptable daily intake.

To finally unite the threads of this story I will return to estrogens, hormonal therapy and cancer. In the mid-1960s a debate on the use of estrogens, provoked by the translation of the bestseller *Feminine forever*, written by the gynaecologist Robert A. Wilson, raised tempers.[19] The question was if menopause is a natural condition to which women should adopt or if it is a deficiency symptom which could be taken care of by gynaecologists. "Wilson wants to abolish menopause with estrogens", read one of the many headlines of the German press. Menopause, lectured the gynaecologist Josef Zander interrogated by Germany's leading news magazine *Der Spiegel*, is a deficiency disease, a lack of estrogens. The only open question for Zander was if acute or prophylactic measures should be taken.[20]

But Wilson's book also caused a heated debate on the dangers of hormonal therapy. *Der Spiegel* even referred to a „Hormon-Krieg" ("hormone-war"). Many physicians interposed that such a use of estrogens besides heavy side-effects could induce uterine and breast cancer. There were not many gynaecologists who reminded their colleagues that sixty years ago estrogens caused tumours in mice, while Butenandt's verdict about the necessary genetic precondition for breast cancer was well and alive in the 1960s. No wonder, Zander was one of Butenandt's disciples.[21] This contrasted sharply to the debate which was going on in the UK at this time and was mostly met with opposition by German physicians. In 1950 Alexander Lipschütz, a veteran of hormone research, published a monograph under the title *Sexual Hormones and Tumors*. He emphasized the connection of those organs, which were controlled by hormones (breast, uterus, prostate), and which could be governed by hormonal therapy, to a vulnerability for tumours. And again, while in the USA hormonal therapy for natal complications and risk pregnancies was common practice, Eric Stephen Horning and Hadley Kirkman from the *Stanford University School of Medicine* were able to induce renal tumour with hamsters inducing estrogens under certain experimental conditions.[22]

The story of the contraceptive pill has been written in great detail.[23] In the early 1960s hormonal contraception was discussed in regard to the risk of thrombosis. But in 1964 the Hamburg gynaecologist Oskar Guhr stated that the pill might induce uterine cancer. His statement was based on only eighty cases, while Gregory Pincus examined a thousand women, which took the pill and were absolutely healthy. Again the journalist Thomas von Randow reminded the readers of the weekly magazine *Die Zeit* of the sad case of *Contergan* (*Thalidomide*) just some years ago: "Even the fact that the pill is taken by millions of women cannot reassure us until Guhr's outrageous suspicion is not refuted".[24] In the following years there was an ongoing dispute. Every clinical study or animal experiment which seemed to prove the cancerogenity of estrogens and DES found its counter-argument and vice versa. While the dosage of estrogens in the pill was gradually low-levelled –to pass the ADI– there still remained a suspicion of the chemical structure of estrogens themselves (reminiscence to Druckrey's dose-time-effect-law). While this provoked a debate on the methods of steroid toxicology, the interpretation of animal tests, the problem of latency, the necessity for long time studies and finally the unsolved difficulties of statistics, many women already reacted as consumers: they abandoned.

The story of the pill is so complicated because there are, in dramatic difference to the 1940s, so many actors: self proclaimed progressive scientists as Carl Djerassi; neo-malthusianists and population politicians; conservative, pro natalistic and biopolitical physicians; a new media hunting for headlines, riding on the sex wave while fanning breast cancer fear; the famous papal encyclical; and last but not least an itself not homogenous women's movement. While for centuries the women's movement was associated with sexual reform and emancipation, in the late 1960s it, as historians like Lara Marks and Barbara Duden emphasize, turned into a consumer's movement, which in Germany followed the example of the 1950s fight for a new food law.[25] Indeed the social and political situation had changed over the 1950s. In 1970, female members of parliament, Hedda Heuser (FDP) and again Käte Strobel (SPD), organized a non-party inquiry regarding the dangers of the contraceptive pill. Feminists, thereby overcoming the former, hierarchical separation of experts/doctors and patients, used the expertises of scientists but also referred to the experiences of women. As part of a consumer's movement the feminist critique of the pill was raised against elitist negotiations of interests and risks, which neglected what was simply going on in women's bodies. The controversy about the pill, as Barbara Duden summarizes, accelerated the transformation of women from patients to self-determined consumers.[26] But thereby they not only lost essentials of the feminist agenda but also inherited the life reform discourse which had been so fundamental in the debate on butter yellow.

CIRCULATING KNOWLEDGE THROUGH LETTERS, CIRCULATING LETTERS THROUGH TECHNOLOGY: THE «EASTWAYS OF SCIENCE» PROJECT[1]

Federica FAVINO[1] Andrea SCOTTI[2]
[1]*Sapienza* Università di Roma, ITALY
ffavino@gmail.com
[2]Fondazione Rinascimento Digitale, Firenze, ITALY

Abstract

Correspondences are one of the most important sources for a science historian: they shed light upon the origins of new scientific theories; they are a privileged point of view to understand the debates of an age of censorship; last but not least correspondences are necessary instruments to understand that extraordinary phenomenon that was the ideal super-national academy of the 17th century European "scientists".
These are some of the reasons why the letter exchanges kept by the «heroes» of modern science still offer material for monumental edition plans. Anyway, if we consider the scientific correspondences as the main source for mapping boundaries, extension, density, population and roadways of the actual "Republic of sciences", the editions on paper –even if philologically peerless– are widely insufficient to manage the huge mass of information inferred from letters. Eastways of Science *is one of the many projects that nowadays exploit the web-technologies to edit, manage and study such documents. It is a research project co-financed by the European Commission, hosted by the University of Rome* La Sapienza *and technologically implemented by the* Rinascimento Digitale *Foundation-Institute and the Museum for the History of Science of Florence. It aims at creating an electronic database that would work as a common repository of letters of scientific-historical interest; a register of the men, women, lecturers, practitioners, patrons, institutions, things etc. involved in such a "Republic" (especially as to Middle-East Europe) in the second half of the 17th Century; a «dynamic» database able to reconstruct the networks of scientific relations that crossed early modern Europe –that is the scientific information flows– making them visible on a geographic map. It focuses on the Academy of the Cimento correspondence, and on its intersections with the epistolaries by Johannes Hevelius and Giovanni Alfonso Borelli.*
This paper aims at explaining and discussing methodologies, ends and temporary results of the project.

[1] §§ 1-7 are by Federica Favino; §§ 8-11 by Andrea Scotti; § 12 is common.

1. Scientific correspondence is an important primary source for early modern European history of science. It throws light upon the origins of scientific theories and their experimental background not easy to detect only by published proceedings. It is a privileged point of view to understand the genesis and development of debates in an age marked by censorship; it is the instrument through which the learned community was construed on the basis of the humanistic ideal of exchange as well as the space where scientific knowledge was produced (think about mathematical challenges or experiment's reports comparison).

But letters do not serve only intellectual history. As to the social history of science, they are often the only means to detect information on those hybrid and apparently "minor" characters that contributed meaningfully to make scientific knowledge, to promote and to spread it, like *amateurs*, public lecturers, draftsmen, craftsmen, instrument makers, trade-men and merchants; as well as on the "minor" institutional settings of early modern science, like universities and colleges, academies and conversations, publishers, printers and booksellers.

As to the «material culture» of scientific enterprise, letters used to work as a vehicle of scientific information (theories, observations, experiment reports, experimental protocols), as well as of objects (letters, books, drawings, instruments, seeds, plant specimens, exemplars to be collected).

In a word, scientific letters are at the same time vectors that fix the boundaries of early modern space of sciences; repositories of a huge mass of information on people, places and objects that populated that space; signs that draw the street-networks scientific information and objects flowed through. A huge mass of data that only informatics technologies are able to detect, to manage and to give back so as to answer the scientific questions made by a discipline, like the history of science, that is getting more and more complex.[2]

2. *Eastways of Science* –acronym for *At the fringes of European "Republic of science": the east-west routes of scientific communication in the age of experiment (1650-1680 ca.)*– is a project co-financed by the European Commission of the European Union under the 7th Framework Programme PEOPLE - Marie Curie Actions[3] and by the Department of History, Cultures and Religions of the *Sapienza*, University of Rome[4], in collaboration with the *Museo Galileo* in Florence, formerly *Istituto e Museo di Storia della Scienza*[5]. The project is hosted by the *Sapienza*'s History Department and is developed by me and is directed by Renata Ago, full professor of Early Modern History[6], with the technological support of Andrea Scotti for the *Fondazione Rinascimento Digitale - New Technologies for Cultural Heritage*, Florence.[7]

3. *EoS* aims at carrying out the prototype of a common web infrastructure that takes into account evidence gathered from scientific correspondences so as to define and highlight the contents the networks and the ways of transmission of scientific information in the north-east periphery of early modern Europe.

More in detail, it aims at:

1. 1 map the network of scientific networks
2. 2 pick-up from letters “quanta” of scientific information
3. 3 follow the information flows on the network

4. To achieve these aims means in practice:

4.1. Populate the existing web infrastructure by means of:

- building a repository of letters
- defining the letters’ extrinsic information (sender, addressee, place origin, place of destination, date);
- defining the letters’ internal information (people, books, instruments, manuscripts, maps, related letters, observations etc.);

4.2. Establish the relations among all found sources in order to be able to navigate across. For instance: expanding search for *ad hoc* combined items could give answers to queries like: who was in 1680 in possession of Hevelius’ *Selenographia* and where (book - date - place)? Which way did Eustachio Divini’s telescope pass from Rome to Warsaw in 1661 (object - dates in between - places)?

4.3. Project these relations on a geo-historical map. This step is still undeveloped.

5. As to time, *EoS* looks at the second half of the 17th century; the age when, in England but on the continent too, «the accumulation of individual matter of facts, socially checked and shared, became the only undoubted foundation of a reformed philosophical knowledge of nature, and scientific correspondences became a selective mean to let the experimental report and the observation’s result pass from the individual domain to the public sphere»[8].

6. As to space, it takes into account the geographical area included in the triangle Rome - Florence - Paris - Danzic, with special respect of the Mitteleuropa areas, that is Poland and the Habsburg Empire’s «periphery» (the yellow area in Figure 1).

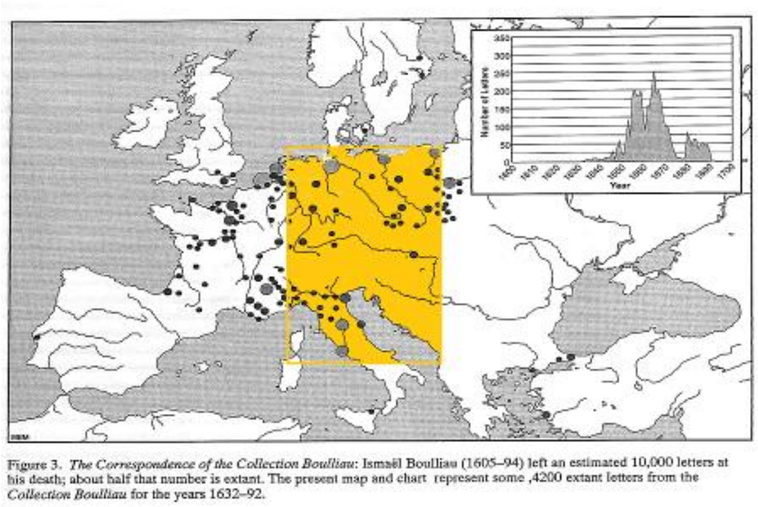

Fig. 1: Source: R. A. Hatch, ‘Between Erudition and Science: the Archive and Correspondence Network of Ismaël Boilliau’, in M. Hunter ed., *Archives if the Scientific Revolution*, Woolbridge 1998, p. 54.

[8] S. Shapin, *The scientific revolution*, Chicago 1996. Cf. also S. Shapin, S. Schaffer, *Leviathan and the air-pump: Hobbes, Boyle and the experimental life*, Princeton : Princeton University Press, 1985; ID. *A social history of truth: civility and science in seventeenth-century England*, Chicago ; London, 1994.

The choice of this geographical area wants to challenge one *topos* of the historiography on the "Republic of letters". While its citizens postulated the ideal of a men-of-letters' world-wide community without frontiers, its actual extent was much less wide than this, limited as it was only to some regions of the Western world. The European *savants* themselves were aware of this discrepancy. In the note to the reader that opened the first issue of the *Journal des savants* (1665), we read: «this Journal, since it aims to advertise what new is going on within the «République des Lettres», will consist of a faithful catalogue of the main books published in *Europe*» (our italics). The «République des Lettres» did not overlap even the whole Europe: listing the countries that provided the books to review, the *Memoires de Trévoux* drew a map that covered only the Continent's Western side. That same year, 1701, the botanist Joseph Pitton de Tournefort (1656-1708) besought the *Royal Society* of London secretary for epistolary contacts with the world of the learned men. Working in the east-Mediterranean countries –he wrote– he was eager for news from the «République des Lettres».

According to two of the main experts of this subject (Hans Bots and François Waquet): «the scanty number of men-of-letters in Transylvania, Moldavia and Valacchia bears witness to the low intellectual density of those countries and to the rarity of their contacts with the West»[9]. Bearing in mind this authoritative judgement, the research we propose here begins with some specific questions: is the scanty density of men-of-letters and learned men accounted for in the 17th century Eastern and Central Europe [see Figures 2 and 3] a matter of fact, or rather it derives from a lack of sources or from inaccurate census rules? And, again: the flow of learned relation between Western and Eastern Europe was indeed a «limited and one-way» flow or rather it was a thick bilateral exchange, as does the map in the picture, drawn by Robert Hatch on the basis of Ismaël Boilliau's correspondence, suggest? [see Figure 1].

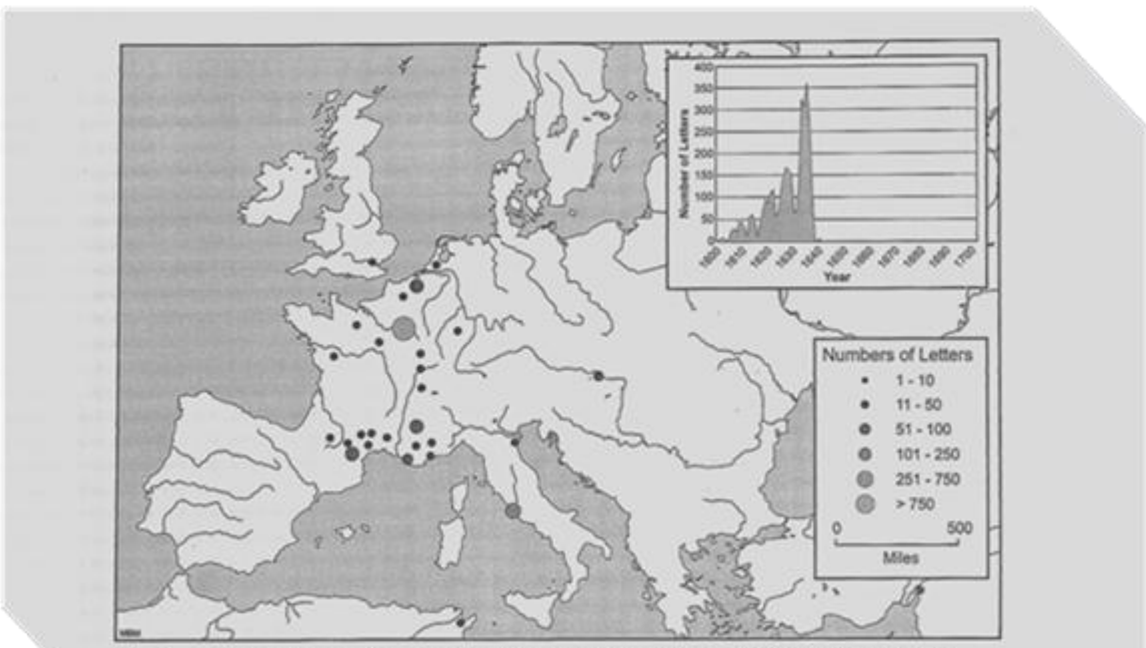

Figure 1. *The Published Correspondence of Peiresc*: Nicolas-Claude Fabri de Peiresc (1580–1637) left an estimated 10,000–14,000 letters at his death; perhaps half that number is extant. The present map and chart represent some 3,200 published letters for the years 1598–1637.

Principe eds., *Accademia del Cimento and its European context*, Science history publications 2009, p. 165-180.

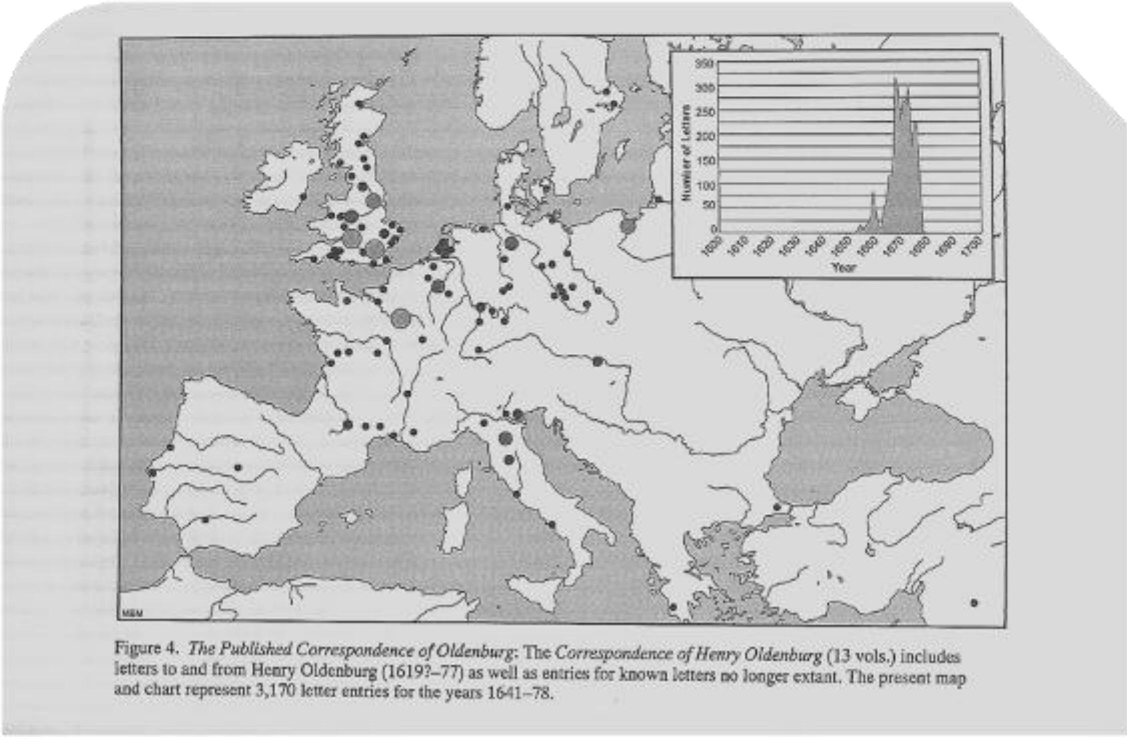

Figure 4. *The Published Correspondence of Oldenburg*: The *Correspondence of Henry Oldenburg* (13 vols.) includes letters to and from Henry Oldenburg (1619?–77) as well as entries for known letters no longer extant. The present map and chart represent 3,170 letter entries for the years 1641–78.

Fig. 3: Source: R. A. Hatch, *Between Erudition and Science*, cit., p. 56.

The *EoS* project means to contribute an answer to these questions by exploiting the web tools: the research aims at reconstructing the networks of the scientific relations which in the second half of the 17th century linked "scientists" and *amateurs* who lived and worked in the western European countries of high intellectual density –that is, France, England, the Netherlands and Northern Italy– and those who lived especially in Poland, Bohemia, Moravia and Hungary.

7. Sources. More in detail, *EoS* project focuses on the space cartographed by letters from and to prince Leopoldo de' Medici and the members of the Academy of the Cimento in Florence (1657 and 1667),[10] crossed with the scientific epistolary produced by Jonannes Hevelius, Polish astronomer, brewer and mayor, who lived and worked in Danzig from 1634 until the end (1687).[11]

These sources have been selected *pour cause* in order to realize our tentative project; they fulfil different criteria, which are scientific, juridical, logistical.

A. They are scientifically promising: by crossing the trajectories even of a sample of letters we can draw the threads of a network that, on the one hand, overlaps the white geographical area I spoke before; on the other, they cross other correspondences networks –like Huygens'[12], Boilliau's[13] or Oldenburg's[14]– already edited or under edition. In a word, they promise to give birth to a wide and thick "network of networks";

[17] Another project focusing on Hevelius' correspondence started at the same time as EoS. It is supported by the CRIT- Cultures, Régulations, Institutions et Territoires of the University of Versailles – Saint Quintin en Yvelines, and is directed by Chantal Grell. Unlike EoS, the CRIT project aimed at editing Hevelius' epistolary on paper.

Fondazione Rinascimento Digitale. The main scope of this project is to provide an open and free downloadable application customizable for the different disciplinary tasks of humanities research.[18]

9. Why Pinakes3? Why choose *Pinakes* as the environment for this project? First of all, because everything produced in *Pinakes* can be exported to any other application. In fact, *Pinakes* stores data in the suggested standard RDF/OWL which allows any other application to see and re-use all information. Secondly, because every knowledge domain can shape its own data structure as requested in *Pinakes*. For instance, what kind of classification can be carried out in the case of the drawing of an instrument quoted in a letter, that eventually could be located in a particular museum, that has been used for particular experiments in many different places of Europe and which other sources also refer to? Here you have a string of different references: a letter, that is a manuscript; an instrument, which is an artefact; an experiment, that is an action; some other references, that could be book engravings or else. Each of these objects has a classification tradition. *Pinakes* allows you to use all the concepts of all these traditions in the same place in order to satisfy each discipline's requirements. At the same time, you will be able to establish relations among all the included objects in an explicit way, so much so that from a highly structured environment you will be able to reconstruct the complex narrative embedded in historical primary sources.

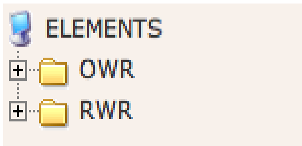

Fig. 6: 1- Elements: The root: abstract class without domain; 2- OWR: Object world reification: the four foundational classes; 3- RWR: Relation world reification: all possible service classes.

10. Pinakes "root" (that is its "upper ontology") *Pinakes* project aims at offering a common methodology of structuring data within the humanities. This means that the long term target is to reach, at least in its foundational concepts, the sharing of a "root" that enables any kind of possible specialization. The foundational schema, i.e. the common root and service classes of *Pinakes*, is structured as follows:

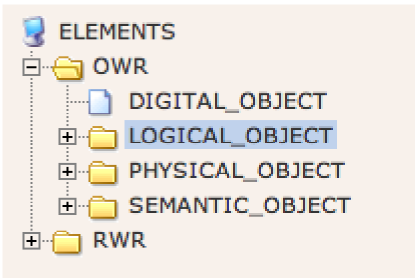

Fig. 7: The four main super classes.

1. The four main super classes with basic attributes:

   1.1. LOGICAL OBJECT: Is a collection of *semantic objects* and is used to describe objects of the reality of which it is possible to have experience/knowledge but that has no physical extension. For example: if you want to represent the events of the life of a scientist you will have a time line among which the facts will be represented into a description. The same thing would be needed if you want to reconstruct the history of a concept such, for example, that of motion or matter. Obviously, each *logical object* can

[18] http://pinakes.imss.fi.it/index.php/Main_Page; A. Scotti, 'Nuove metodologie e tecnologie nella storia documentaria della scienza : l'esempio di Pinakes', in M. T. Monti ed., *Antonio Vallisneri: l'edizione del testo scientifico d'età moderna. Proceedings, Scandiano, 12-13 ottobre 2001* - archiviazione, lo studio e l'interrogazione di documenti digitali di cultura', in I. dal Prete, D. Generali, M. T. Monti eds., *Le reti in rete* [electronic resource]: *per l'inventario e l'edizione dell'Archivio Vallisneri*, Firenze 2011, p. 31-52.

have relation with a *physical object*, but also the latter can be knowable only due to a *semantic object*, i.e. there is no possible knowledge without a whatsoever given denotation.

1.2. PHYSICAL OBJECT: is any object of realty that has an extension whose attributes can vary due to the different needs of the single disciplines/projects. The attributes of this object are therefore the basic ones of any possible physical object: matter, dimensions, property. The latter is also a foundational attribute because no existing object been placed somewhere has a juridical status of property: a landscape belongs to a state in the same way that an artifact belongs to a museum or private individual.

1.3. SEMANTIC OBJECT: is the denotation of any possible physical or logical objects. The attributes of such object also vary by means of the knowledge domain. For example a book has a physical description in measure, number of pages etc. but is knowable only due to its title (our semantic object). An archivist will describe such object in a way that can be very detailed whereas an historian would not need all those details but simply a reference record. These variations in number and type of attributes will not interfere with the fact that the title of the archivist and that of the historian belong to the same class of semantic object, so both would be found by the browsing.

1.4. DIGITAL OBJECT: this is a special class that has been set here (among the foundational classes) for simplification reasons. In fact whereas all other classes are abstract and can be specialized, this one in not abstract (meaning that it can have instances) and cannot be specialized. This class describes the main required attributes of any born digital object, for example its weight (KB, MB, GB etc.), its extension (mime type), its URL, etc. And is always a range of any possible *semantic object*. In this way all digital collection can be grouped by means of their description but also by means of their attributes and can be browsed as such independently of their denotation, for example by a pattern recognition engine.

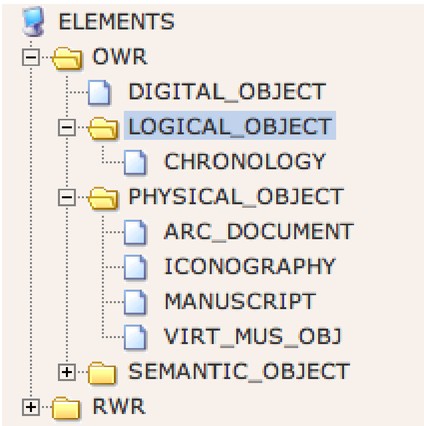

Fig. 8: This is how the root of *Pinakes* foundational ontology has been specialized in order to classify all the possible objects to be found in the scientific correspondence of *EoS* network.

2. The four main service classes:

2.1. ACTOR: this is a super-class that represents all possible typologies of actors (human, animal, fictive, physical etc) and can be specialized.

2.2. ACTION: this is a super-class that represents all possible typologies of actions (voluntary, involuntary, processes, flux etc.).

2.3. TIME: any portion or point of any given time line with all its possible representations.

2.4. SPACE: any knowable area or extension, with all possible declinations from measurements to toponyms.

2.5. SIMPLE TYPES: this class groups all the so-called primitives, i.e. all those types required to make machine readable information such as: String, Integer, Float, etc. This class cannot be specialized because it already includes all required type for any machine usable at the time being.

11. Pinakes 3.0: short functional description. The *Pinakes 3.0* application is distributed under the regulation of the so-called General Public License and undergoes the rules of the copy-left. This means that anyone interested in using it as it is will be authorized to do so, and that anyone interested in participating to its further development will be authorized to do so by taking part in the *Pinakes 3.0* developer and user community.

We are going to show here three of main functional in which this application is divided:

1. The *management area* where, on the basis of the existing methods in the application (an upper-foundational ontology), the user can define using its own taxonomy (a set of concepts depending on the discipline) –in the case presented here the History of Science– by means of the correspondence which implies:
   - how detailed the description of the objects should be;
   - what type of relations objects should have with other objects;
   - what kind of indices would be used and where or how to create them;
   - what should be published on the web and what should not;
   - which data can be shared and which not;
   - who does what and at which level of authorization.
2. The *classification area* where the user can:
   - input data using its own definitions and, in case it is needed, re-edit them according to a given method;
   - refine the definition of information and knowledge domain according to new needs found along the research activity;
   - browse and use data belonging to other projects that may be relevant for his/her on own research;
   - use and/or offer other projects relations and indices definition if needed;
   - get access to the digital repository of all projects and use, under the Intellectual Property constrain, all digital objects (images, moving pictures, music, etc.);
   - define a data navigation for the purpose of editing them;
   - get access through the web to other databases in order to capture data and import them in a given project (this according to the rules of Intellectual Property);
   - access external (out of the *Pinakes* project) digital repositories to capture new resources or refer to them through the automatic creation of a web address (this according to the rules of the Intellectual Property and copyright);
3. The *navigation area* where the user can:
   - get access to all data produced controlling the publication of his own data and, if needed, go back to the input to edit them.

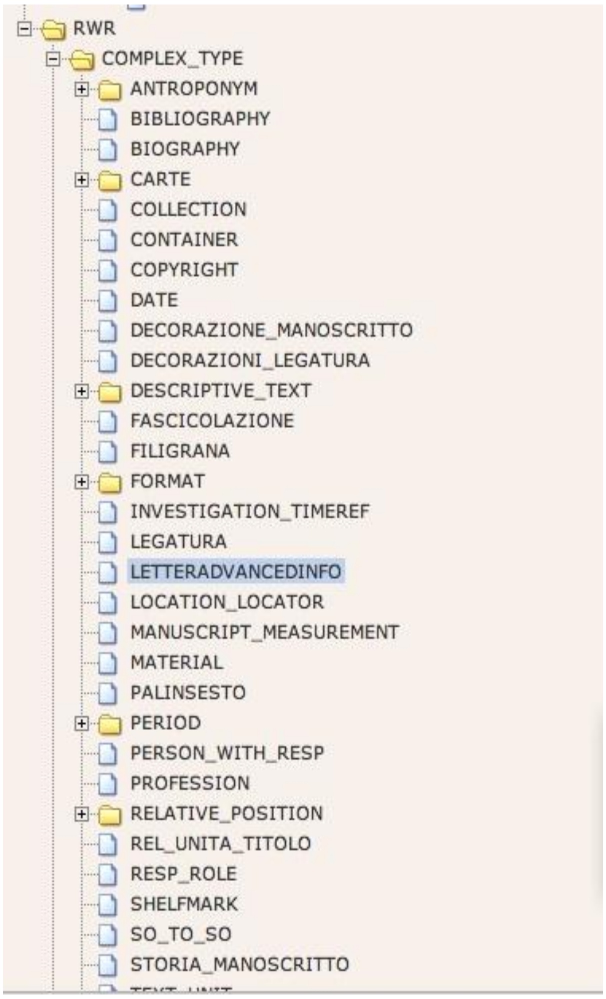

Fig. 9: The specialization of the Relation World Reification class, i.e. the so called service classes that allow describing all what the project requires. Here only a part of the class tree is visible.

12. The structure of EoS data in Pinakes 3.0: some input samples

NEGOTIATING MEDICAL AUTHORITY IN EARLY MODERN PHYSICIANS' EPISTOLARY NETWORKS

Michael STOLBERG
Universität Würzburg, GERMANY
michael.stolberg@uni-wuerzburg.de

Abstract

In 16th- and 17th-century medicine letter writing played a crucial role. Numerous physicians participated in extensive epistolary networks. Their letters covered a wide range of topics, from new theories and empirical findings to political and confessional controversy, from the challenges and rewards of medical practice to domestic affairs. They were much more than a means of communication, however. In the absence of scientific periodicals, epistolary networks constituted the principal public sphere in which the success or failure of new books and ideas was decided upon and in which some authors rose to the position of an authority while others remained controversial or were marginalized. In their letters, early modern physicians could exchange their opinions and criticism of individual authors and books much more quickly, widely and openly than in books. This paper will draw on a sample of more than a thousand manuscript letters written, for the most part, by physicians –some famous, some hardly known– in the German-speaking areas between 1530 and 1650. The letters are taken from a database which is at the core of a 15-year project on "Early modern physicians' letters" started in early 2009 at the Institute for the History of Medicine in Würzburg under the auspices of the Bayerische Akademie der Wissenschaften *which will ultimately provide access to many thousands of early modern physicians' letters via OPAC. As the paper will show, a thorough analysis of such letters offers unique insights into processes involved in the creation of new medical authorities and into the relative importance of criteria such as originality, learning and style, association with established authorities or intra-professional and moral conduct which prompted the appreciation or rejection of an author and his work.*

In recent work on the history of science and medicine, the processes and strategies involved in the construction, confirmation and rejection of scientific authority have attracted considerable interest. Examining the rhetoric of scientific texts and illustrations, the strategic function of footnotes, prefaces, dedicatory epistles and similar devices has become a very fruitful and increasingly sophisticated field of historical inquiry. And last but not least the impact of communicative practices on scientific authority has undergone closer scrutiny. Successful "networking", to use a modern term, has been identified as a crucial strategy for the acquisition of authoritative status.[1]

Especially in the 16th and 17th centuries, in the virtual absence of scientific periodicals, epistolary networks constituted a major forum in which the success or failure of new books and ideas could be decided upon and in which some authors rose to the position of an authority while others remained controversial or were marginalized. Letter writers could also exchange their opinions and criticism of individual authors and their works much more quickly, widely and openly than in books thus providing the historian with a more immediate access to the actual processes and criteria involved in the attribution and denial of authority.

For historians of early modern medicine, correspondences offer a particularly interesting and revealing source in this context. Firstly, medical authority was at the time in certain respects still very precarious. Frequently it rested to a considerable degree upon the physician's fame as a medical practitioner. But diagnostic and therapeutic skills were much more difficult to validate and much more open to debate than, say, empirical observations. In retrospect, there is little reason to believe, in fact, that the most famous physicians of the time had much better therapeutic outcomes than the most humble barber-surgeons. Nevertheless, some physicians achieved international renown as highly skillful practitioners and their advice was sought eagerly be kings and princes all over Europe while others fell into disrepute. Medical authority in medicine, this implies, was to a very high degree the result of successful professional self-fashioning.[2]

Early modern physicians' correspondences: a new data-base

In what follows, I will present the first results of a survey of about 3,000 physicians' letters written between 1500 and 1650. These letters come mostly from a data base of the correspondence of early modern physicians in the German-speaking areas of early modern Europe, which was started in Würzburg in 2009 under the auspices of the *Bayerische Akademie der Wissenschaften*.[3] The aim of this project is to identify and make accessible 10,000s of letters written by and to doctors in the German-speaking areas in that period. In many cases, the database offers detailed freely searchable summaries of the letters' contents as well as the names, works and places which are mentioned. By the end of 2011, the database is to go online. Scholars from all over the world will then have access via internet and free of charge to the data and the summaries of the contents of an increasing number of letters. They will be able to search for specific names or subjects, such as "Paracelsus", "town physician", "*aurum potabile*" or "eucharist" and in some cases they will also be able to download a digital image of the original letter in question.

Letter writing

So what can we learn from early modern physicians' letters about the ways in which medical authority was established, strengthened, questioned or rejected at the time? First of all, a major feature of early modern epistolary networks –as of most networks– were processes and strategies of inclusion and exclusion. Becoming part of an epistolary network –moving in the "right circles"– already constituted an important step towards the acquisition of authority –and it could pose a serious challenge. For authors who had already acquired fame thanks to their printed works or to their position at a renowned university or court it was fairly easy. Here the major question was whether mutual interests justified the effort (and expense) involved in maintaining a correspondence. But often a young and/or unknown physician turned to an older, more famous and experienced physician –and here the success was much less certain. The early modern "medical republic of letters" as it was occasionally called at the time, was far from open and egalitarian. Rather, the processes and strategies resembled in many ways those familiar from systems of clientelism. Just as in the case of personal visits, the "lower-ranking"

physician usually needed the recommendation of an established physician who was already part of the network. Even then letters of introduction would praise the prospective correspondent lavishly, mention if possible some other renowned personalities he was already acquainted with and offer his services –for example in procuring books or plant specimens. Sometimes a young or unknown physician also simply wrote to a famous physician, without anyone to recommend him. Surviving letters, in which the writer mentioned or complained about not having received an answer to his first attempt or in which a physician regretted in retrospect that he had not accepted and opened a letter which had been sent to him suggest that indeed many if not most letters which lacked personal recommendation remained unanswered and ended up in the chimney fire.

For those who made it, becoming part of an epistolary exchange with more or less famous personalities, could entail a considerable boost to their authority. Letter-writing was much less a private affair than today. Letters were shown around. Sometimes –indeed this was very common practice– correspondents would also ask to greet friends or acquaintances, which allowed the lower-ranking physician to underline that he had personal contact with a well-known authority. Lower ranking physicians could also use epistolary contacts to ask a well-established authority for medical advice or even obtain a council for individual patients from him, which would raise their standing among their patients. Their local physician, the patients were made to understand, personally knew one of the famous personal physicians of this or that duke or prince – who, with all the money he had, undoubtedly accepted only the best medical care he could find.

Sometimes physicians might even publish the letters they exchanged with famous physicians and thus further boost their own standing. The German surgeon Wilhelm Fabricius of Hilden is a good striking example. Around 1600, at a time when surgeons still very much battled to get academic respect, he managed to put himself at the center of a growing epistolary network of academic physicians. His fame rested above all on the publication of his correspondence combined with his own observations and those which his correspondents had communicated to him. And the fact that Fabricius promised to publish their letters as well may well have enticed others to enter into an epistolary exchange, too, which would make them appear as part of a circle of highly renowned physicians.[4]

If necessary, letter writing could also serve as a welcome tool to defend oneself against attacks from others, to repair one's own public image or that of friends. Thus Carlo Avanzi, in 1638 complained to Michael Besler that Johannes Vesling had become the head of the botanical garden in Padua without knowing much about plants. He had outmaneuvered Avanzi –at least this is what Avanzi claimed– by spreading calumnies. But Avanzi had taken revenge: he had made a fool of Vesling asking him to identify some very common kitchen plants like parsley and mustard in front of 200 invited students. According to Avanzi's account, Vesling had, of course, miserably failed, and by telling this story in a letters to his German correspondent Besler, Avanzi made sure the news would spread also in Vesling's home country.[5]

Of course, epistolary networks were not just about medical authority. They could also serve other purposes –though many of these other purposes could at least indirectly also contribute to a physician's authority. Letters could offer intellectual stimulus and exchange especially for those who worked in rather isolated situations. They could give access to the latest political and local news. They were an excellent and widely used means to spread the word that the author was just about to complete a new book which would soon be on the market. They provided a welcome opportunity to test colleague's responses to new ideas or findings. And in numerous letters the correspondent was also simply asked to buy and send certain books, or correspondents mutually exchanged seeds, plants, minerals or other specimens related to natural history, as part of a highly elaborate epistolary gift culture. Sometimes a correspondent might also quite straightforwardly seek support in his effort to secure a new position or to attract new patients. In this sense young Prospero Alpino, for example, asked Joachim Camerarius to help him open the doors to the German community in Venice and Padova.[6]

Just being part of the circulation of letters and knowledge as such, it seems, was perceived as being of considerable value. This is well illustrated by the numerous letters which, at a closer look, lack any real content. This can be rather frustrating for the historian who seeks to analyze them but it is a very revealing feature. These letters served simply to confirm that the epistolary "friendship" still existed. Quite commonly correspondents even expressedly stated that they actually had nothing to say, nothing to write about, or that they had had a hard time finding the topic which they now proposed to discuss. Sometimes correspondences were also marked by long intervals of silence –and yet at some point one of the two resumed the exchange, without any obvious reason and with little to say.

Even some of the most famous physicians of the period attributed considerable importance to maintaining epistolary networks far beyond immediate, pragmatic, utilitarian considerations. Some, like Theodor Zwinger in Basel must have spent a substantial part of their time answering the thousands of letters addressed to them which have come down to us. In spite of

the considerable time needed for maintaining an epistolary network and of the expenses for forwarding the letters, examples of physicians who were, on the contrary, reluctant to enter into epistolary exchange are rare. Felix Platter, Zwinger's colleague in Basel is one of them. He was undoubtedly one of the most renowned physicians of his time and was frequently contacted by others. But his surviving letters tend to be extremely short, and those addressed to him suggest that he often preferred not to answer at all. Why he acted in this manner we do not know for sure. He was a busy man –but so were many others. Probably he could afford to do without an epistolary network better than most of his colleagues thanks to his outstanding and financially rewarding position as a practitioner in Basel: he counted most of the patricians and aristocrats among his clients. But as a look at his surviving letters suggests he may also not have felt quite at ease with the demands of elegant Latin letter writing.

Medical authority

For many early modern physicians maintaining a good epistolary network was a privileged means of acquiring and maintaining authority within the learned medical world. But what can we learn from their letters about the construction, questioning and refutation of early modern physicians' authority? On what grounds did early modern physicians accept certain colleagues as authorities and rejected others? Much more research is needed in this area and it should include prosopographical studies which would look at how physicians with different training and different strategies of self-fashioning fared. A closer analysis of their letters does already bring to light, however, some major criteria which guided their judgment.

A first feature is very familiar to historians of early modern society but it is nevertheless worth underlining: authority and fame in the early modern republic of letters were not only attributed based on scientific or literary achievements. Virtue was an indispensable prerequisite as well. When correspondents mutually praised each other or when they wrote about other physicians' good moral qualities, like "humanitas" and "pietas" were often presented as crucial. Without them physicians could not expect to be accepted as an authority. Vice versa, criticizing the moral qualities of an opponent –the wide-spread slandering of Paracelsus is a good example– was a very promising strategy when it came to undermining an opponent's medical and philosophical standing.

A second attribute which had much greater importance than today was eloquence and style. Thus Leonhard Bausch praised Georg Agricola –not so much for his mineralogical findings but for his elegant Latin style.[7] Elegant style also had to be demonstrated in the epistolary exchange itself. For good reasons, fathers of future physicians asked their sons to correspond in Latin with them. A simple Latin mistake could have disastrous consequences and the word of such linguistic incompetence might spread quickly. Thus Joachim Camerarius in a letter to Sigismund Schnitzer reported the story of a Spanish scholar in Nuremberg who had translated various texts into Latin and was admired for his linguistic skills –until one day great shame fell upon him: he had quoted Priscian wrongly with the expression: "Hispanus est rex omnium regorum" instead of "regum" –a blatant blunder of which Camerarius and Schnitzer who later published his letter helped spread the news.[8]

The high esteem for an elegant style went hand in hand with great appreciation for learning in general, a learning which letter writers often also sought to demonstrate in their letters, too, scattering them with quotes from the major works of ancient Roman authors or indeed short phrases from Greek works in Greek script.

Of course, scientific authority in a more narrow sense also played a major role. Early modern physicians had heated debates on medical theories and, especially in their publications, sometimes attacked each other viciously for disregarding – or, vice versa, for adhering slavishly– the views of Galen, Hippocrates or other ancient authorities.[9] His adherence to a specific school of thought as such provided only a limited basis for questioning a physician's authority, however, except if it could be linked to reproaches of a lack of piety, virtue or learning as in the case of orthodox criticism of the Paracelsians.

In debates on medical matters another argument was much more lethal: deviation from factual, empirical truth. The early modern period saw a pronounced shift from a focus on the truthful representation of authoritative texts to the truthful representation of nature, based on careful and well-informed observation. This shift can be perceived already in the 16th century in epistolary exchanges about matters of natural history, an area in which many physicians took great interest. Leonhard Fuchs for example could hardly have expressed himself in more devastating terms about Pietro Mattioli. Once his own book was out, Fuchs declared, everybody would see that he had corrected Mattioli, this "arrogant", "inflated" Italian, in hundreds of instances.

[9] Cf. for example the vitriolic disputations by Johann Freitag, *De paradoxis et erroribus novae sectae Sennertiano-Paracelsicae*, Groningen 1635.

The esteem for factual truth was closely linked to a growing appreciation of empirical findings, which was the driving force behind the dramatic rise of another criterion: originality.[10] It came to the fore above all in the guise of the accusation of plagiarism. He hoped that the author was not selling other people's work as his own, Georg Agricola even said about Andreas Vesal's famous *De humani corporis fabrica libri septem* before he had seen it.[11] Fuchs, in turn, was adamant that Conrad Gesner was making a too liberal use of the work of others, that he had indeed sometimes integrated entire works by others, like Rondelet's work on fish, into his own, and intended to do the same with Fuchs' work.[12] This accusation reflects the growing importance attributed to original work, to original, empirical findings in early modern science and medicine but it was also heavily fraught with morals: plagiarism was incompatible with the image of a virtuous physician whose ultimate aim was the good of mankind and not the selfish promotion of his interests.

In many respects then, medical correspondences were a major site for the negotiation of early modern medical authority. Their analysis offers important insights into the strategies and processes involved and can thus ultimately also contribute to our understanding of the reasons why some authors, theories, findings and books were highly successful and influential while others remained marginal or were quickly forgotten.

VERBA VOLANT SCRIPTA MANENT: THE IMPORTANCE OF CORRESPONDENCE IN EARLY MODERN MEDICAL DIAGNOSIS

Annarita FRANZA
Università di Pisa, ITALY
liverpool1940@alice.it

Abstract

The aim of my talk is to underline the importance of correspondence between physicians in Early Modern medical diagnosis. The paper studied the correspondence between Romolo Spezioli, personal physician of Queen Christina in Rome and the famous Italian scientist Marcello Malpighi. The research examines the serial of letters that is kept in Archiginnasio Library and in University Library in Bologna. The collection of letters, unpublished and unstudied, offers a unique example of medical correspondence full of details about the description of diseases and therapy in the 17th century and it represents an important source of reconstruction of the epistemological approach to catarrhal diseases in Early Modern medicine.

During the 17th century, a doctor's reputation was determined by many factors, the culmination of which was an improvement in the patient's health and, if possible, a complete recovery. Personal medical visits, the easiest to carry out in terms of clinical procedure, certainly contributed to making a doctor's therapeutic successes known, but it was difficult to go beyond such limits of a typical 'medical practice'. Once having achieved a good, local reputation, the physician devoted himself to long-distance medical consultations to get around this limitation. These took the form of epistolary communications, which placed the hopes for a patient's recovery –sometimes someone whom he had never met in person– in a written opinion sent by post known as a *consilium*.

In order to define the *consilia* –the dense and interconnecting documentation of advice supplied, requested, and received by physicians– I have divided my presentation into two parts. The first offers a brief survey of the *consilium* in a very technical sense as a specific literary genre of practical medicine. In the second part, I would like to point out some levels and forms in which the consulting practice and circulation of opinions, which defined a physician's skill and the extent of his influence, were expressed by analyzing consultations signed by Marcello Malpighi, the Italian scientist (1628-1694), and by Romolo Spezioli (1642-1723), the personal physician of Queen Christina of Sweden during her stay in Rome (1654-1689) and court physician to Pope Alexander VIII[1]. The first relates to the ill-health of Cardinal Girolamo Gastaldi's sister (1616-

[1] Cf. F. Zurlini, *Romolo Spezioli (Fermo 1642- Roma 1723). Un medico fermano nel XVII secolo a Roma*, Roma 2000; Ead., Fabiola Zurlini. Cultura scientifica, formazione e professione medica tra la Marca e Roma nel Seicento. Il caso di Romolo Spezioli, Macerata 2009.

1685)[2] and the second to the illness that led to the death of the powerful Venetian cardinal Pietro Basadonna (1617-1684)[3]. An examination of these documents, now stored in Bologna at the Archiginnasio and the University Libraries, will show how these documents are not merely a collection of data and symptoms, but rather present a microcosmic overview of the different epistemological levels of seventeenth-century medicine, with special reference to etiological research and the treatment of catarrhal illnesses.

What is a *consilium*? Critics have suggested several definitions, all subject to revision by whoever does not find them completely satisfactory in respect to the texts encountered in their own research, or finds the definitions so broad that lose any historiographical usefulness. Perhaps, it was this kind of uncertainty that led Jole Agrimi and Chiara Crisciani, editors of Les *Consilia médicaux*[4], one of the most comprehensive studies available on the subject, to provide a definition that takes into account the possible subgroups, specific cases and their evolution. The authors therefore have suggested an ideal model that, while not always reflected *per se* in the actual texts, is certainly useful to provide a preliminary framework. A *consilium* is therefore a document in which a physician, following the rules of a codified writing discipline, formulates regarding a current, individual case of a pathology in which the illness is defined and an appropriate treatment is prescribed[5]. A form of epistolary communication, these documents are, therefore, an indispensable tool for translating a by and large literary document into a professional one. Thus, a vast sea of well-established literature was created, which served as the empirical foil to speculative treatises in institutional manuals and the theoretical foundations of the various medical systems.

Alongside the vast river of published *consilia*, there is a parallel current of unpublished works –often for centuries and according to the criterion of ills (*a capite usque ad calcem*)– that ran flowed in the initial period of their evolution. This does not mean that these forms of scientific communication may not also have circulated in various handwritten copies among a circle of insiders and the patient's relatives and created some debate on the issues raised[6].

This is the case, for example, with the illness that struck the sister of Cardinal Girolamo Gastaldi. Her state of health so disturbed the soul of that illustrious prelate that he was driven to write a letter dated 6 July 1684 to the famous Marcello Malpighi, asking for a *consilium*, and including a consultation by another, less well-known physician, Romolo Spezioli[7]. This latter set of papers, enclosed with the epistle, are now lost. Nevertheless, research conducted at the Bologna's Archiginnasio Public Library has brought to light an unsigned *exemplum* (report)[8] that summarizes the patient's physical symptomatology together with the medical treatment prescribed by Spezioli[9]. In this way, we learn that the noble woman, frail of body but of cheerful temperament, is plagued by various kinds of maladies, such as erysipelas, (intermittent) ephemeral fevers as well as a shortness of breath and continual coughing that degenerated into pleurisy. Spezioli's direct knowledge of the disease through personal observation of sputum –sticky, white or sometimes a very dark color– led to clearing up the painful disease in which certain afferent bodily fluids, corrupted by the poor coction of humors, gave life to a rotting waste, concentrated particularly in a series of catarrhs in the upper respiratory system. To purge the rotting bedsores and allow the body to regain the lost crasis, the doctor prepared decoctions made from goat's milk serum, borage and Prunella salt[10] and medicines to counter the atrabilious components of the humors, restored the proper degree of fermentation as well as bled the salvatella[11].

The clinical picture and therapeutic treatments just highlighted were confirmed in Malpighi's consultation of 9 August 1684 when, in answer to the prayers of Cardinal Gastaldi, the physician from Crevalcore reassured him of the suitability of the assistance being given to the sick woman[12]. The *consilium* is divided into three sections. The first gives an account of the resulting unhealthy situation; the second and third prescribe medications and therapeutic interventions to be adopted. These include a way of life based on the proper use of the six *res non naturales*, the only area in which the patient can make a behavioral practice for which the *consilium* provides precise guidance. It must be emphasized that the consultation's structure by topic where indications that may lead to presuming a personal visit are few and indications of the 'distance' are

greater, making the document a typical exemplar of a *consilium in absentia*[13]. Among those indications that stand out are the need for a theoretical and doctrinal completeness in the first section with its precise list of symptoms related to the pituitary, including persistent night cough, and the critical scrutiny of those symptoms with a view to understanding the etiology of the disease, getting over the bad coction of the chyle and the consequent stagnation and fermentation of corrupt sera in the upper viscera. This is not a simple display of erudition, but a manifestation of a diagnostic method, where the consulting magister works, at a distance, with his books and coordinates with his teaching the discreet work of attending physicians, seen as intermediaries between the literary authors and the patient's body.

As can be developed doctrinally and related also or above all to skill, Malpighi's consultation was however a public document that circulated both within the Gastaldi family circle and among physicians in Bologna and Rome. Attention is drawn to the "competition" between the expert consulted and the consulting physician as the letter that the physician and mathematician Domenico Guglielmi sent to Malpighi[14], once again at the request of Cardinal Gastaldi, to take the case of Cardinal Pietro Basadonna, one of Spezioli's patients and who was afflicted with a severe urological complaint. The long-awaited consultation never took place as the illustrious prelate died that same day, 6 October 1684. Nevertheless, research in the archives of the University Library in Bologna has permitted tracing the *consilia*, drawn up by Spezioli on the Basadonna case, probably summed up –as suggested by Guglielmini's letter– in the message forwarded to Malpighi[15].

In relation to the singularity of the case, the structure of the *consilium* became established and had an epistemologically important effect on the diagnosis of pituitary diseases with the wording in the first section of the paper, of the *casus in terminis*: the elderly Cardinal's symptoms were thus subsumed in a abundance of corrupt humors in the urogenital region whose withered putrescence was the cause of both urination disorders suffered by the elderly cardinal and the suppurating tubercle that, as a result of the decubitus of the catarrhal waste, was found between the neck of the bladder and the base of the kidney. According to this skeletonizing process, the patient's data and symptoms (*signa narrata*) became conclusions that corresponded to texts often cited in detail. The authors that appear in all sections of the *consilium* make the latter an alternative to the printed page, as a means to teach and train, showing not only the sophisticated medical training of its author, but also a precise framework within which to resolve the epistemological search for the underlying causes of disease. The reading of classic and modern primary sources has been joined with a direct observation of the disease, thereby resolving the pathological etiology of catarrh in a particular canon of healing. The diagnostic outline thus inferred led Spezioli, with an amazing intuition for the state of the art at that time, to attribute the clinical picture to a fault of the blood, pathogenically unrelated to non-specific symptoms of dysuria, vesical tenesmus, and pyuria. The explanation of the disease's etiology followed the treatment guidelines, evacuated and purgative in nature, designed to correct the corrupt matter in the blood to allow restoring the correct crasis of the bodily fluids.

In conclusion, the literary genre of the *consilium* is better than other documents the path of medicine as a practical science, as a discipline consisting of a *pars theorica* and a *pars practica* where one is conceived in terms of the other and vice versa. The texts analyzed here are excellent examples of this policy: the *consilia* of Marcello Malpighi and Romolo Spezioli, with their references to a wide range of therapeutic interventions such as phlegmatic diseases, are important documents to understand how the medicine of the time wished to go beyond the simplistic definition of *ars mechanica* that was sometimes attributed to it. Spezioli's texts, in particular, are very eloquent in this regard because, rather than presenting the reader with a descriptive and bibliographical survey of the case under study, they offer a bibliographical diagnostic description, which supports and corresponds to a bibliographic therapeutic record in which it summarizes a changed knowledge of medicine, aimed at the universal tense but always subject to experimental revision and control.

THE ZOOLOGICAL COLLECTIONS OF THE *MUSEU DE LISBOA* AND THE NETWORKS OF SCIENTIFIC CORRESPONDENCE AND EXCHANGE (1858-1898)

Catarina MADRUGA
Museu Nacional de História Natural da Universidade de Lisboa, PORTUGAL
cmadruga@museus.ul.pt

Abstract

In 1858, the royal zoological collections hosted in Lisbon became part of the Polytechnic School (1837-1911) to be of assistance to the classes in Zoology. The previous «Museu de Lisboa» at the Royal Academy of Sciences was now to be organized following proper scientific and up-to-date knowledge. José Vicente Barbosa du Bocage (1823-1907), as the head professor in Zoology, became in 1859 the Director and first organizer of the "Zoological Section of the Museum of Lisbon". Through his work and direction the royal collections became a museum designed as part of the exchange network of specimens and the scientific knowledge within.

To discover, collect and send home to Europe natural objects and images of the new world was a comprehensive task held by many naturalists whether with an academic, military or religious background. Nevertheless, the understanding of the knowledge held in all the thousands of specimens being brought to European collections and exchanged between European societies, academies and universities was now being completed inside the collections storage rooms.

In this paper we analyse the correspondence of Barbosa du Bocage to his foreign peers aiming to contribute for a clearer picture of the importance of the network established between private collections, universities and museums in the construction of new knowledge in the study of nature at the second half of the nineteenth century. We argue that some influential authors were organizing knowledge about nature from inside the museum's walls and that the way the trade of specimens inside Europe was made is of major importance for the production of knowledge. Analysing the relationships established between these authors (their institutions and nations) and other professors, collectors, patrons, diplomats, naturalists and taxidermists may facilitate the study of scientific knowledge production.

With this paper I aim to present the available data from an on-going study of the vast correspondence of the director of the zoological section from the *Museu de Lisboa*[1], José Vicente Barbosa du Bocage (1823–1907), with his international peers attempting at a possible outline of his personal and institutional networks of scientific correspondence from the year 1858 and the following four decades. I will begin with an introduction of the overall setting, then briefly go through Bocage's biography, and finally address three of the most occurring typologies of correspondents identified so far.

Biographical draft of the Zoological Collections from the Museu de Lisboa

After the big earthquake in 1755 the new Royal collections were organized in the Royal Cabinet of Ajuda (Palace of Ajuda, Lisboa) and grew as ship loads came from abroad, from several places in the globe, arriving at the Lisbon port. Furthermore, the Marquis de Pombal refurbished the Palace of Ajuda with a Botanical Garden, a Chemical Laboratory and museums to where he called on Domenico Vandelli (~1735–1816) to assure its scientific organization.

In 1808, during the French Invasion, the still incipient arrangement in the Ajuda Museum received an imminent Zoologist's visit from the Parisian Jardin des Plantes: Geoffroy Saint-Hilaire (1772–1844) was the naturalist selected to accompany the French troops and 'collect' from the natural history collections of Lisbon. He was accompanied by Vandelli himself, whm later stated he had tried to «make the best deal possible» with Geoffroy –who had in his agenda the commitment to complete the French natural collections of the Americas, especially Brazil.

The first decades of the Portuguese nineteenth century were all but quiet[2], and even with great directors as Vandelli and Avelar Brotero (1744–1828), and with the collections of Alexandre Rodrigues Ferreira (1756–1815), the natural history collections didn't develop. When these collections arrive at the Polytechnic School, they are welcomed by Barbosa du Bocage, who inherently with his professor post becomes the responsible «Director» of the Zoological Section of this Museum. In fact Barbosa du Bocage, as the main Zoology Professor, was the official receiver[3] of the very large set of collections held at the Academy of Sciences, collections that had previously come from the Royal Cabinet of Ajuda, Lisboa. He becomes thus associated with the growth registered from then on in the zoological taxonomical studies in Lisbon. In fact, the zoological section of the museum later came to take his name –and became to be known as "Museu Bocage"[4].

José Vicente Barbosa du Bocage (1823-1907)

Barbosa du Bocage was born in Funchal (Madeira) into a family that was –due to the political instabilities in Portugal at the time– moving between Madeira and Brazil. He graduates from Coimbra in 1846 with a Baccalaureate in Medicine that will later take him to Lisbon to become an attendant at the Hospital de São José. In 1849 he becomes assistant lecturer in Zoology at the Polytechnic School –becoming a part of this, by now consolidated, educational project. In the following years, he marries Teresa Roma (1851) and begins an extraordinary career as a zoologist (publishing in total around two hundred papers on taxonomy) being part of the Lisbon's intellectual sphere (member of the Royal Science Academy, and a founding member of the Geographical Society in Lisbon, where he was President from 1877 to 1883) and the politician sphere as well, particularly after his retirement as Professor; who was involved in trying to contribute with new and pragmatic ideas for the country[5].

He becomes the Chair for Compared Anatomy and Zoology in 1851 and amplifies his interest in zoological studies. While he is part of the Polytechnic School board of professors, in 1857 he publishes his first important work on Portuguese zoology and taxonomy, describing the by now extinct Portuguese Ibex (Cabra do Gerez) making use of the Royal Collections from the Prince's Cabinet. His later works with the Museu de Lisboa's Collections *Ornithology of Angola*, or *Herpetology of Angola and Congo* –just to name a few– were international references in the field.

---

[1] The *Museu Nacional de Lisboa* was established at the Polytechnic School of Lisbon by decree in 1858 (Dec-Lei 09.March.1858) holding two different sections: Mineralogy and Zoology, its main purposes to manage the collections from the Academy of Sciences of Lisbon, and to use them as didactical support.

[2] Several civil wars disrupted the Portuguese society throughout the first half of the nineteenth century.

[3] There was a formal session held at the Academy of Sciences in 1858, where Bocage was the official representative of the Polytechnic School.

[4] In 1905, the Polytechnic School Board rendered homage to Barbosa du Bocage and decreed the Zoological section of the school's museum as «Museu José Vicente Barbosa du Bocage».

[5] He was in 1866 called to the Education Council, and became in 1881 a member of the Câmara dos Pares do Reino (with legislative powers) and then in 1883 to the Fontes Pereira de Melo administration to be Naval Affairs and Overseas Minister; and again in 1890, he was part of the government of João Crisóstomo taking the Foreign Affairs when he was in charge with the difficult negotiations of the British Ultimatum (1890).

In 1875 he holds the office of Secretary at the Science Academy in Lisbon and by 1886 he was a corresponding member for the Zoological Society of London, the Natural History Society of Strasbourg and the Royal Imperial Zoological and Botanical Society of Vienna. Unfortunately, this Museum section suffered from a major fire in 1978, leaving the collections with almost nothing from the past specimens or memories. Fortunately, many of Bocage's papers, folder, manuscripts and correspondence still exist today.

From 1858 on, Bocage dedicated himself to the promotion of a large network of contacts, asking yearly budgets for new purchases, and soliciting more and more specimens from other museums and collectors. These would seem strange requests –specially knowing that the school's building storage rooms were still under construction– if we didn't take into account that the value of zoological collections lays fundamentally on its ability to compare with large reference collections. The Lisbon collections were still not properly identified or catalogued and Bocage felt the urgency of gathering more "knowledge" than the available on the specimens he had to study.

The "Sedentary Naturalist"

> *If the sedentary naturalist does not see nature in action, he can yet survey all the products spread before him. He can compare them with each other as often as is necessary to reach reliable conclusions. He chooses and defines his own problems; he can examine them at his leisure. He can bring together the relevant facts from anywhere he needs to. The traveller can only travel one road; it is only really in one's cabinet that one can roam freely throughout the universe.*[6]

This quote underlines the role of such *sedentary naturalists*, as naturalists do not produce new knowledge all by themselves –they need expeditions, comparative collections and networks. A *sedentary naturalist* is, in this context, a particular scientific persona that represents a node of a larger and essential network of contacts, aggregating places, materials, texts and books, and all the available information.

So, immediately after hosting the collections into the recent rooms of the department, Bocage begins the immense task of organizing them systematically –so that they could be used for both didactical and scientific functions. It is from this moment on that Bocage will insist with the School's Council to be excused from the teaching tasks, in order to focus on the research with the collections. He soon realizes that, in order to become an appropriate systematic zoology museum, this would need large increases of specimens not yet available in the collections.

In 1859 he asks for, plans and carries through a major digression to acquire specimens and establish connections with other European museums, what we today would call an exchange network. Zoological specimens, but also taxonomic information and scientific books and periodicals, travelled between nodes that could be scientific personalities or institutions. Bocage leaves on a European Tour during the School's summer break to visit not only Paris, but Madrid, Brussels, Strasbourg, Leyden, London and Frankfurt –and he makes contacts not only with museums, and museum staff, but also with taxidermy tradesman, field naturalists, specimen merchants, etc. With his tight budget he buys specimens, books, taxidermic supplies as well as didactical cutting edge material for the classes back in Lisbon.

Always having in mind the many systematic gaps that 'his' museum had missing, he chose as main strategy to try and invest in the comprehensive completion of the animal groups (Classes) of which the museum already had some specimens. For him, as stated in his reports, it is better to have a 'whole' group than groups with 'holes' on them.

The process of augmentation of the collections made possible by Bocage had more than one approach. The expeditions to the far corners of Africa, South America or India didn't stop in the meanwhile. And in an effort to better the results of these expeditions Bocage published in 1862 his *Instrucções praticas sobre o modo de colligir, preparar e remetter productos zoológicos para o Museu de Lisboa* (Instructions on how to collect and send specimens to the Museum in Lisbon). Also in 1863, the Royal collections of the king D. Pedro V are donated and transferred to the museum. All this was maybe sufficient for a study collection to serve the classrooms at the Polytechnic School, but it seems clear that the collections were from the beginning being considered by Bocage as serving much more than a didactical purpose. In order to be able to develop scientific work in zoology, quantity of specimens and suitable reference collections are of major importance.

Networks of Correspondence

Following, I try to provide a brief analysis of the network of scientific correspondence, exchange and trade of zoological specimens as part of a designed strategy of augmentation of the collections. Barbosa du Bocage was related with his peers in museums and academies from all over Europe and beyond: so far this study has already documented twenty-

---

[6] Georges Cuvier as quoted in Dorinda Outram "New Spaces in Natural History", in Jardine, Nick et al *Cultures of Natural History* (Cambridge: Cambridge Press, 1996) pp.260-266.

eight correspondents, with epistolary relations ranging from 1858 until 1900, mainly written in French but also in English and German, with correspondents from seventeen cities from fourteen different countries, with no registered complaints or misunderstandings of word meanings. There are even specific phrases that are left in the original language independent of the exchange language used.

The content of the letters is varied although, as expected, mainly about taxonomical considerations or problems, or on the transaction details of specimens, ranging from commercial dealings to letters with a more intimate and personal tone.

It may also be interesting to make a note of the role of mediator that Bocage occupied between other foreign zoologists and the Portuguese crown –he was many times asked to forward letters, specimens or publications for appreciation by the king himself. Bocage is certainly a preeminent figure with a high status and sufficiently close to the crown; surely King Dom Pedro, as later D. Luís and D. Carlos, had an interesting reputation amid naturalists, but it is still remarkable that Bocage represented such an important connection.

Some letters indicate close and almost intimate relationships between scholars and Bocage himself: there are some remarks on his wife's health and compliments on his son's accomplishments with his scientific instruction.

From the letters this study processed so far, becomes apparent that several authors play significant roles inside the networking of this period in Europe, regarding knowledge on zoological specimens. From the epistolary relationships identified, an attempt was made to categorize them into their own taxonomy. I will consider for this paper as *network nodes* – correspondents that provided clusters of more than three letters from the same source that may allow a picture of a specific correspondence relationship. The study so far comprehends three different clusters of correspondence: trade and commercial affairs; trades between museum naturalists; and between diplomatic contacts. Other cluster that may be identified and characterized in the future is, for example, the periodical publications exchange between journal editors and naturalists.

Commercial exchange (specimens for money)

Commercial liaisons are more formal, as would be expected, but significantly cordial in allowing for mishaps in the long journey transactions to happen, and offering to make replacements of broken glass containers, for example. Many different commercial arrangements may be made depending on the quantity requested –more specimens bought equals less money spent in each, which may suggest an interesting study to be made on the monetary value attributed to each *taxon*.

There seems to be a great investment in the seriousness of the business –it is after all dealing with scientific, objective knowledge and thus, traders resolve their legitimacy and authority regarding classification, with the collaboration of 'uninterested' savants from universities or academies that help build the advancement of science, even if it is for commercial purposes. This seems to be a very interesting modus operandi since there is an objective trade value attached to each specimen but simultaneously a sort of detachment associated with the scientific knowledge principles and values. The expected jargon of 'the best offer' and 'buy now!' is present even if under a coating of formal and polite writing, as in the following example:

> Je vous envoie ci joint la liste de deux belles collections de Reptiles dont je me suis rendu acquéreur. Il y a des pièces bien rares principalment parmi ceux d'Australie. C'est le premier choix que je vous offre. De certaines espèces, je n'ai qu'un seule exemplaire. [...] J'ai aussi [...] espèces [...] tous nommés par le Savant Icthiologue Professeur Bleccker.
>
> A. Boucard (12.VIII.1873)[7]

In the excerpt presented[8], the same letter legitimates the goods through the recognized authority of Professor Bleccker –as a sign of authenticity and care for the proper serious specimens' identification. Adolphe Boucard (1839–1905) was himself a known field naturalist, but for his commercial transactions chose to have another name associated with his own authority as a collector, to reinforce his authority also as a trader.

Some phrasing is also used to apparently detach the discourse from the pure commercial interest, like the expression *«je me suis rendu acquéreur»* as if the purchase of such items were a sort of a random, non intentional event. The formality of the letter also seems to relate more with gentlemen prose than with straightforward commercial transactions of material goods. These marks may be explored further as a different type of transaction appears, one that falls in between commerce and intellectual exchange blurring boundaries between both.

---

[7] Manuscript correspondence from the historical archives of the Museu Bocage – Museu Nacional de História Natural da Universidade de Lisboa [AHMB CE.B.27].

[8] The available correspondence with Adolphe Boucard (from both Paris and London) continued from 1873 to 1875, counting six epistles exchanged between Bocage and Boucard.

Museum Collections (specimens for specimens)

Regarding another sphere of transactions, it is a distinguished feature for natural history museums to act as repositories of doubles, to be used in direct transaction with each other. Even if the museum is a shared arena between several specialists, curators still tend to work with collections in a very personal way, since *new species* discoveries would still occur; authorship was still an important marker for distinction. The networks would also serve the purpose to render "hot news" from one place to another, since it is normal for this kind of epistles to be sent along with specimen samples or doubles, as material proof but also material representation of a specific issue or information[9]:

> Vous me permettez de vous envoyer en même temps que cette lettre quelques épreuves de coquilles fossiles du miocène supérieur de Steinheim Aalbuch (Württenberg), du genre Planorbis ou Carinipex (autrefois Valvata), qui échauffent au moment tous les paleontologistes et conchyologistes allemands Darwinians ou Non-Darwinians.
>
> O. Boettger (14.X.1877)[10]

This community of savants was so much engaged with the progress of scientific knowledge that was indeed advancing very rapidly by then, that book corrections were taken as part of a *shared knowledge*.

> Je vous remercie pour vos observations au sujet des ***Bucorvus*** et quand je fais quelques fautes, je veux bien qu'on me corrige.
> Vous avez raison, et je suis en erreur [...]. Nous cherchons que la verité, et dans ce but il faut nous corriger les uns les autres. Maintenant, pour les autres figures nous ne sommes pas encore d'accord. Pour savoir d'ou vient la fleuve il faut monter à la source. ...
>
> D. G. Elliot (01.XI.1877)

A very interesting feature of these letters is the attitude towards scientific knowledge sharing and the common understanding that taxonomic knowledge could only increase via and intense comparison and critical observation and reflection, circulating in a large network of experts.

Correspondence with Daniel Giraud Elliot (1835–1915)[11] was written while Elliot was staying in Paris in 1877 and this cluster mentions corrections made to his article by Bocage, by his own initiative, and a remarkable inquiry shared by both Elliot, Bocage and another zoologist in Germany on the correct description of one of the Ground-hornbills (Bucorvinae). There was an exchange of specimen descriptions spurred by the noticeable differences noted between German specimens in a catalogue description and Bocage's own description of his own specimen in Lisbon. Elliot also mentions John G. Keulemans (1842–1912), the skilful Dutch artist whose depictions he relied on to further inquire differences between the three birds and whether the Lisbon specimen was indeed unidentified, and therefore *new* to science. Museum catalogue descriptions were not comprehensive enough when it came to specific traits, and not all specimens had individual depictions in engravings or drawings. In this case, direct comparison between specimens was only attained through an intense epistolary exchange between the various nodes.

Diplomat liaisons and "donations" (specimens for honours)

In an epistolary transaction between Bocage and Barnet Lyon[12], other commodity values that scientific natural history specimens may have become evident. Albeit Barnet Lyon is, at the time, the Netherlands consul in Belgium, he writes to Bocage in order to ask for assistance to his brother –the Portuguese crown consul in Suriname, in getting the right contacts in Lisbon for a shipment of natural objects destined to the Museum of Lisbon. Barnet Lyon wanted to know to which of Bocage's *contacts* he should address the cargo to, and whether to send it via Amsterdam or London. In addition, he proposes another shipment: a collection of 150 models of exotic fruits he possesses, and that he wishes to *gift* to the Portuguese crown.

---

[9] Correspondence with museum curator Oskar Boettger (1844-1910) from the Senckenberg Museum Frankfurt, Germany lasted, at least, from 1877 through to 1893, and was written in French.

[10] Manuscript correspondence from the historical archives of the Museu Bocage – Museu Nacional de História Natural da Universidade de Lisboa [AHMB CE.B.20].

[11] American naturalist, founder of the American Museum of Natural History, New York and curator of zoology at the Field Museum, Chicago.

[12] This specific episode of correspondence with George Henry Barnet Lyon (1848–1918) went on mainly during 1868 [AHMB CE.L.18-21].

> si cette collection, dont une pareille, a été achetée par le Musée Britannique, loin de l'Exposition Universelle en 1862, pourrait être agréable au Gouvernement de Sa Majesté, je serais aussi très flotté et heureux, de pouvoir l'offrir.
>
> Barnet Lyon (19.[?].1867)

That a certain *gift economy* should be a part of the diplomatic networking is to be expected, and of course museums depend on their overseas national officials for a big part of their travels and transactions, even so, that the diplomatic liaison was to be so closely intertwined with the 'scientific' network amongst European nations is an interesting feature that needs more study and reflection. In this first letter is noted that the Portuguese consul in Suriname doesn't have a direct contact with the capital, Lisbon. And also that it is via the natural objects exchange that this connection will, in fact, be established. In the following letters, both from Barnet Lyon and his brother, Bocage carries on the exchange of several deliveries from Suriname via Barnet Lyon (in Brussels) until at least April 1869, when he receives a thank-you note from Sally Lyon, still in Paramaribo, Suriname. Sally Lyon had just received notice of his appointment for the Honorific Order of the Conception of Villa Viçosa, of which he was made an official "Cavaleiro". This may be an example of how these donated "gifts", be they specimen data or supplies, are transferred with the consent of the donor not for material or tangible profit but for social prestige, as several honours are being exchanged alongside the scientific materials. In this particular case, in the end of the day, honorific titles were «traded» off for specimen collections.

Exchange of Nature, Nature of Exchange – Closing considerations on the nature of a zoological specimen

Possession of 'nature' is obtained from different procedures that engage different kinds of behaviours. There appears a specific 'gift economy', as defined by Marcel Mauss, a particular circulation of goods in societies. Even modern scientific production is known to entail some of the characteristics of this kind of shared community, when scientists publish papers and quote one another's produced knowledge in roughly the same 'detached' offering way. In the correspondence analysed there were several markings of this kind of shared knowledge. Small pieces of knowledge were traded along the network in order to fill in gaps of a larger puzzle: the systematic inventory of nature, controlled, stabilized and sanitized inside the museum walls. Scientific knowledge is exchanged openly over national borders and languages, in a tense relation between the ideal knowledge and control over nature, individual scientists and their localized institutions.

THE CORRESPONDENCES BETWEEN THE MATHEMATICIANS BRIOSCHI, CREMONA, BETTI AND GENOCCHI DURING ITALIAN UNIFICATION.

Nicla PALLADINO
Università degli Studi di Salerno, ITALY
nicla.palladino@unina.it

Abstract

In the 50s of the nineteenth century, there was the necessity to organize new structures in the borning Italian State: the Unification of Italy marked a turning point not only in the political life of the Country, but also in the organization and content of university education and scientific research. A group of mathematicians helped to build the foundation for the renewal and development of Italian mathematics that took place in the following decades. This group included, among others, Francesco Brioschi (1824-1897), Enrico Betti (1823-1892), Angelo Genocchi (1817-1889), and Luigi Cremona (1830-1903).
I want to present here the epistolary correspondence between Brioschi and Cremona and Betti and Genocchi,[1] *covering the period from the mid to late 19th century, provide greater insight into scientific developments and political-institutional arrangements that took place at the time of the formation of the new unified Italian state.*

Mathematicians of the first magnitude, who came from different States existing in Italy in the 19th century, gave a great impulse to the formation of the Italian State and devoted themselves to give it new cultural structures. The letters between two Lombard scholars, Francesco Brioschi and Luigi Cremona (these letters were written from 1855 to 1893) and between Enrico Betti, Tuscan, and Angelo Genocchi, from Piacenza (their correspondence goes from 1862 to 1886), refer to a period in which different States of the Italian peninsula were transforming or failing and to the following unification of the Italian Kingdom.

From a chronological point of view, these letters cover almost all the second part of the 19th century, while their authors are the most important mathematicians of Risorgimento, due to their scientific capacities and their both direct and indirect political action (it is important to mention also Battaglini, Sannia, Casorati, Beltrami).

---

[1] [PALLADINO *et al.* 2009].

All these scholars were well-known and of great value, but Brioschi had the most complex personality. His letters, addressed to Cremona, ninety-two, are stored in "Istituto Mazziniano - Museo del Risorgimento" in Genova –*Legato Itala Cremona in Cozzolino*– while those written by Cremona are just six and they are in "Biblioteca Centrale della Facoltà di Ingegneria of Polytechnic" in Milan. Even if Brioschi was a virtuoso in computation in topics he chose[2], he dedicated his studies to engineering with a great didactic, institutional (thanks to unitary feeling and his institutional role as General Secretary of the Ministry of Public Education, in 1862, he organized the "Istituto Tecnico Superiore" –now *Polytechnic*, opened in November 1863– in Milan, serving as director from 1863 until his death) and entrepreneurial commitments. In his letter of 10th July 1865 to Cremona, Brioschi describes his choices: "Unfortunately, my activities at the school don't give me the possibility to dedicate more time to mathematics [...]. Moreover, I have a lot of courses because there is a lack of teaching staff; from November to May I have taught nine hours every week on theory-building and hydraulics. This explains why I work so hard but I can't publish any work: even if I reach a result, I have no time to present it".[3]

Brioschi held important institutional roles: General Secretary of the Ministry of Public Education, member of the Executive Council of the Ministry of Public Education, when Florence first and Rome then, were capital of Italy, president of the *Società Italiana delle Scienze*, known as *Dei XL*, president of the *Accademia Nazionale dei Lincei*, *Consigliere di Lungotenenza*[4] and, as senator, he participated in the commission elected by the Minister of Finance to talk about the tax on flour.[5] He also was director of *Polytechnic*, journal founded by Cattaneo in 1839 and director of the *Annali di matematica pura e applicata*.

As a matter of fact, the new Italian Kingdom needed to be built up and reorganized and Brioschi, able to examine the European situation because of his open-mindedness and with a good education (his tour with Betti and Casorati round German universities and Paris in 1858 represents an evidence[6]), strong-willed, with spirit of enterprise and never exhausted, wanted to be always present (in his opinion, "six o seven days of the month were wasted travelling"[7] to go from Milan to Florence first and to Rome then, were good for his health, even if "this changed a lot his habits as scholar"[8]).

A man divided by the love for scientific research, which he at times practised, regretting the continuous interruptions and rejoicing at his renewals, as it is possible to understand in his letters to Genocchi, and his attraction for action, inspired by his strong self-esteem: when he accepted to be *Consigliere di Lungotenenza*, Brioschi explained his choice:

> "If I hadn't been in Rome those last days and I hadn't seen what there was to do, I probably wouldn't have accepted; I convinced myself that it was necessary to deploy great activities and a wary energy, all qualities I can rely on. For this reason I will send a dispatch of acceptance right now".[9]

But Brioschi's masterpiece was the creation of the *Istituto Tecnico Superiore* (he took as model German polytechnics) and he was able to keep it alive and, with great care, grow it thanks also to a little expedient to "catch" new students: instead of forcing students to pass the preparatory two years in Mathematics at the university, where they were tempted to stay keeping on their studies, they were sent to the polytechnic of Zurich or Lausanne (where courses started a month before) and then, because of "good reasons, difficulties of languages, health…",[10] they were directly transferred to three-year periods, superficially interpreting Italian law. In Milan, Brioschi also organised a "semi-official" course of one year and students were directly transferred to three-year periods.

The correspondence Brioschi-Cremona doesn't show the leading role of Cremona (in 1898, for a short period he was Minister of Public Education and then he was appointed a senator. He had a great influence on post-unitary Italian educational system) and this also because Brioschi kept few works of his pupil first and colleague later. As a matter of fact, during his years at the University of Pavia, Brioschi was Cremona's professor and patron: thanks to Brioschi, he gained

permission to teach at the Ginnasio in his city and at Liceo Beccaria in Milan –before the Italian Union– and then, "well-disposed to talk to the Minister about your aptitude for teaching and the importance of your works"[11], Brioschi obtained that Cremona was appointed as professor at the University of Bologna.

Cremona did his best to unify Italy: the first sign is the journey around south of Italy, in 1863; it was not only an ideal continuation of his relationship with Neapolitan volunteers during the defence of Venice against the Austrian, but it seemed also a recognition to know the problems and act better.

At the end of the battles of Solferino and San Martino, in an atmosphere of militant euphoria, Cremona was risen up by Brioschi to a higher level then a pupil, as he really did at the *Instituto Tecnico Superiore* and in the *Annali*.[12]

From Genocchi's letters (in "Archivio Betti", stored at the library of Scuola-Normale in Pisa; Betti's letters are at the Passerini–Landi library in Piacenza) the importance of his personality emerges. He was not a simple spectator destined to applaud others:

> "I thank you for your dedications: I always read them. But I am old and I can't see always the same words. Even if I desire to do a lot of things, my strength fails me; and I can just applaud people braver and more capable than me".[13]

Genocchi is fifty, he is the oldest of the group, but he was the only one to dedicate his entire day to research (he confessed to Betti: "I prefer my quiet more than the interference of a chair"[14]); he had a lot of interests but the most important was mathematical analysis and theory of numbers. He also was a great scientific interlocutor: he read, asked for explanations, reflected and honestly commented works that his correspondents sent him; it seems that they often used him as a "tester" to verify the quality of their works. He was a sort of "scientific uncle" also ready to "spank" Giulio Ascoli.[15]

As every letter in which Genocchi is the correspondent, also these addressed to Betti had a high scientific density. They talked, for example, about problems of didactics of mathematics ("to force to explain Euclide"[16] in Italian schools) but also other important questions: there is a long discussion on pseudo-spherical surfaces, about which the sceptical Genocchi said that, to continue discussing it is essential to "demonstrate that these surfaces exist"[17]; in letter 27[18] there is another important discussion with Betti (in the sixties, he was dedicated to research about the theory of elasticity[19]) where Genocchi showed his uncritical acceptance, as it was usual at that time, of "postulate" according which "all functions have a derivative".

Genocchi was austere and severe (he disagreed, for example, with the way that Universities, the *Consiglio Superiore* of Public Education and the Ministry overused *art. 69* of Casati Law, that is to say the direct call-up, "for good reputation", of professors[20]) but he was partial for professors of the University of Turin: he often conducted their defence and he was always ready to give them his recommendation, both for less good and for the best.[21] When a good fight entered in his heart, Genocchi always dedicated to it the right consideration, as it happened for the admission of Sonja Kovalevski at the Academy of Sciences in Stockholm: in Italy he became active to support her admission.[22]

During the correspondence with his Turinese interlocutor (his letters are fifty-one while Betti's answers, always short, are twenty-four), the Tuscan scientist, who, during the formation of the Italian Kingdom, often went to Turin as deputy of Pistoia and could meet Genocchi, was involved in that issue because he was member of the *Consiglio Superiore* of the Ministry of Public Education and for his studies in physical mathematics. The letters 12, 18, 26, 31, 38, 59[23] from Betti to

Genocchi are very important: those letters present some consideration about non-Euclidean geometry and Helmholtz's physiological optics.

The documents here collected until now represent the most important cards of a patchwork setting up the time when a country, Italy, that, even if varied, was joined together after so many centuries under the same entity of State and it tried to build a stronger political, civil and scientific future: that historical period required the presence of great national states and the Italian ambition was that of conquering an outstanding place in the European nations "concert" or, at least, the honor of a first line place in the "haute culture" under the great "Italians" flag that until the 17th century had lived up to the whole peninsula. This is the direction where Genocchi, for example seems to look at when corresponding with Betti; he praised the scientific activity carried out by the latter:

> "You also work a lot and with your and Italy's honor. I cannot play any other role than the spectator and I am delighted in clapping the talented actors".[24]

The epistolary exchanges published in this volume, fitting together one in another, realize images evoking a heroic period lived by the Italian people or, at least, from a coat, much as thin, of it. These are images representing rush actions, gone along with a considerable sense of dignity. We can also compare the publishing of these epistolary exchanges, still, to the act which gives voice to some poets; they take part in a choir which can bank on a large number of qualified voices.

The new structures and the new rules building up in this time, will impress on a territory wider and wider since, at first, the Kingdom of Sardinia with the united Lombardy (a sort of "Regno dell'Italia Superiore" as Brioschi writes[25]), and they will find themselves being broadened, a month later or so, to the Italian Kingdom with Turin as its capital at first, from 1861, and then Florence from 1865 to 1871, to pass afterwards to Rome. An important example, from this point of view, is given by the passing of the *Casati Law*. It concerned the whole public education, of every order and rank, and it approved a part of the law project presented, in 1854, from Cibrario, Minister of the Public Education of the Kingdom of Sardinia. The *Casati Law*, thought for the "Superior Italian Kingdom", will be expanded gradually, with some modifications and integrations, to the whole Italian Kingdom: it was elaborated according to a politic view and it assigned to the highest level of education a constitutional organism function which had to ensure the birth and growth of a national science, the formation of the class heading the country not submitted to the clergy influence, the validity of the educational qualifications, the access to the freelances, the grounding of new grammar school professors and so on. Consequently to the listed reasons, the *Casati Law* calculated to give to the State the entire control and the financial burden of the superior Education, cutting out any private or clerical participation.[26]

A progressive, considerable documentation is collected supporting the statement according to which, once the Italian Unity reached, it produced a renewed involvement for research, an increase in the chances offered to the experts. In particular, the mathematics enthusiasts –that had previously already found the way, on the occasion of the invitations to the yearly *conferences* of the *Italian scientists* which went over from 1839 to 1847,[27] of giving themselves some "solemn occasions" of meeting and, subsequently, they continued actively to look for each other– could take more advantages of the new politic affair. With a remarkable enterprise, they made a good use of the motivating forces that came from the natural intensifying of their relations. Having an edge, in living this occasion of growth, from the fact that their need of scientific equipment and teaching aids were not, as the usual procedure of that time, very strong and so to compromise, in the absence, their capacity of realizing their potentials.

The starting limits outlined a picture of backwardness –less evident in the Grand Duchy of Tuscany, though of little size entity (but where they were well decided, after the risings of 1848, to close the two Universities existing at that time, Pisa and Siena, which were later re-opened by the provisional Government of Tuscany in 1858-59)– in some districts in Emilia and Romagna and in Piedmont, that could count, looking to the grass roots, on a quite strict and common ethical behaviour but, especially, it could have a controlled State deployment; and where also the capital before the Italian unification, Turin, was enriched in some measure by the people who came from the different states of the peninsula, taking refuge there. It is known that during the so-called "preparation decade" for the Unity, many exiles, leading figures of the future Italian governing class, were received in Turin University (but not always with full acceptance by their colleagues). However, the state apparatus of the Piedmont monarchy, despite the presence of a Parliament (the Kingdom of Sardinia was the only Italian state having a Parliament), got to wield forms of control, over its own governed people, even too extreme; more or less in the way of a Bourbon government, as it seems to be from Genocchi's uneasiness confided to Brioschi.[28]

The south part of the peninsula, the south which Cremona knew personally and a little bit better both for thrusting to the far provinces[29] and for staying in Naples for many,long times –it was in this city that his daughter Itala lived as wife of the Neapolitan doctor Vincenzo Cozzolino–, was a definitely a different world.

It already was, anyway, a cause of wonder if the Kingdom of Naples along with Sicily (the largest and most populated of the reigns before unification, and the second for richness production after the Lombardo-Veneto), preserved itself, in broad cultural, civil and religious terms, clung to the European continent. It was a piece of Italy that was felt as far away. But, even if in its irregular way of life in the crowded capital, which naturally represented its core, the Kingdom of Naples could be proud, if nothing else in the Italian area, of some supremacy[30] and could count upon the presence, often very active in the capital and somewhere else, of all those institutions, including the cultural expressions, which connoted a country as civil while, provided with a large hard-working youth, and studious,[31] mainly centered in the capital itself, it had its intellectuals' view addressed to the central and northern –more advanced– part of Europe with which they actively interacted.

THE RECEPTION IN THE WESTERN AREA OF A SAME METHOD FOR TWO MEDIEVAL ASTROLOGICAL PRACTICES

Montse DÍAZ-FAJARDO
Universitat de Barcelona, SPAIN
mdiazfajardo@ub.edu

Abstract

In Islamic medieval astrology, there were three basic practices used to cast a horoscope: 'the determination of the celestial houses', 'the prorogation' and 'the projection of rays'.
A horoscope is a representation of the celestial sphere in a specific moment and for a given latitude. The equator and the ecliptic are maximum circles of the celestial sphere; the ascendant of the horoscope depends on the local horizon. One or several of these circles intervened in the computation of the above mentioned practices. Likely, this fact helped to the establishment of a link between them, even though they had different aims and an independent development with their own methods.
My study is devoted to the connection between the prorogation and the projection of rays and to the dissemination, in the Islamic West, of a common method for these techniques: The Single Hour Line Method. To date, what we knew about it is that it was the standard calculation for the projection of rays since the 9th century.
However, in the Islamic East in the second half of the 10th century, The Single Hour Line Method was also used for the prorogation in a book dedicated to the prince of Aleppo Sayf al-Dawla (945-967) The Introduction to the Craft of Astrology *by al-Qabīṣī. In the Mediterranean Western Area, the popularity of al-Qabīṣī's book was such, that its Latin translation was still being printed in 1521.*
The Single Hour Line Method for the prorogation was followed as well by a Moroccan astrologer of the 15th century, al-Baqqār: in his text, the use of several technical terms denotes that it was written by a Western astrologer. The present work is based in al-Baqqār's contribution.

Introduction

This article deals with an astrological procedure documented in the Islamic East, The Single Hour Line Method for the prorogation, and its reception in the Maghrib in Abū 'Abd Allāh al-Baqqār's work (fl. Fez, *ca*. 1411-1418) (Díaz-Fajardo, 2001; Guesmi, 2005) *Kitāb al-adwār fī tasyīr al-anwār* (*Book on cycles for the prorogation of the celestial elements*) where this method incorporated principles of the Andalusian astronomical tradition.

In this paper I shall explain: (a) how prorogation and projection of rays are related by means of The Single Hour Line Method, a common method for both astrological procedures; (b) the sources in which al-Baqqār is based and (c) the transformation of this common method in the Islamic West.

The Single Hour Line Method

In the projection of rays and the prorogation, The Single Hour Line Method distinguishes the computation according to the position of the indicator on the meridian, on the horizon or between the meridian and the horizon. For briefness, in this paper I only consider the case of an indicator placed on the meridian.

1. Relation between prorogation and projection of rays

The prorogation and the projection of rays were indispensable appliances for interpreting a horoscope, and they are based in mathematical computations that follow astronomical rules. There is a basic astrological concept in both techniques, the celestial element which is placed in the circle of the ecliptic, may be moved on the same circle of the ecliptic or on the circle of the equator. This motion has the purpose of reaching another imaginary position in which the astrologer establishes the celestial influences.

1.1. The Single Hour Line Method for the projection of rays

The projection of rays states that a celestial element (a planet generally) sends its nature or influence to a second element. The planetary influence can be beneficial or malefic and brings to the second element the change of its original condition.

The act of transmitting the nature is known in Arabic texts as projection of rays and it takes place when the second celestial element is placed within the domain of the planet, namely, when between the planet and the second element there is a distance of sixty, ninety, one hundred and twenty, or one hundred and eighty degrees.

The most common calculation for the projection of rays was The Single Hour Line Method (Kennedy and Krikorian-Preisler, 1983: 372-375; Hogendijk, 1998; Hogendijk, 2005: 91-92; Casulleras, 2007: 38-41; Casulleras, 2010: 88-92), which owes its denomination to the scholar Jan P. Hogendijk. This method remained in use in the East until the first half of the 15^{th} century and in the West until the 14^{th} century.

When a planet is placed on the meridian, the simplest procedure is employed, and its computation is as follows: the right ascension (α_0) of the longitude (λ) of the planet (p) is added to the number of degrees of the ray (R) (sixty, ninety, one hundred and twenty, or one hundred and eighty degrees) = $\alpha_0(\lambda p) + R$.

The projection of the ray equals to the former amount converted into ecliptical degrees = α_0^{-1} [$\alpha_0(\lambda p) + R$].

1.2. The Single Hour Line Method for the prorogation

In the prorogation technique, the first indicator, a significant celestial element for the subject of the horoscope like his ascendant, may be moved or prorogated on the circle of the equator in order to find a second indicator that, due to its malefic nature, has the ability of stopping the motion of the first element. The two indicators delimit an arc on the equator that, in medieval Arabic texts, was called 'prorogation arc' which is the distance between both indicators in equatorial degrees. The equatorial distance agrees with time according to a system of equivalences that matches equatorial degrees and years, months or days. In this way, the astrologer could determinate the date of any event.

The prorogation was also used in a second way consisting in the computation of the ecliptical degree or terminal point at which the motion of the celestial element finishes for a specific year.

The computation for the latter purpose works as follows:

When the indicator is placed on the meridian, the right ascension (α_0) of the longitude (λ) of the indicator (d) is added to the number of total solar years (Y) elapsed since an event, for instance, the elapsed years since a birth until the date in which the horoscope is cast or until the date in which the prorogation is calculated = $\alpha_0(\lambda d) + Y$.

The terminal point of the prorogation is equal to the former sum converted into ecliptical degrees = α_0^{-1} [$\alpha_0(\lambda d) + Y$].

As we may see this procedure for the prorogation and the procedure of projection of rays explained in section 1.1 above is the same method: it is the standard calculation for the projection of rays called The Single Hour Line Method, but applied to the prorogation technique. The total solar years (Y) elapsed since a specific event must be used in the computation for obtaining the prorogation instead of the number of degrees of the ray (R) used in the projection of rays:

Terminal point of the prorogation = α_0^{-1} [$\alpha_0(\lambda d) + Y$]

Projection of ray = α_0^{-1} [$\alpha_0(\lambda p) + R$]

The use of this method in the prorogation technique and its relation with The Single Hour Line Method for the projection of rays had not been identified, until now.

1.2.1. Sources

The Single Hour Line Method for the prorogation was followed by the Eastern astrologers al-Qabīṣ ī (fl. Mosul, 10th century) (Burnett, Yamamoto and Yano, 2004: 124-126), Kūshyār ibn Labbān (Gīlān, *ca*. 971-1029) (Yano, 1997: 232-235) and al-Bīrūnī (Khwārizm, 973-*ca*. 1048) (*Kitāb al-qānūn*, III: 1393-1395; Hogendijk, 1998) and by the Western astrologers Ibn al-Raqqām (manuscript (ms) 2461, National Library, Rabat, p. 222) and al-Baqqār in his *Kitāb al-adwār* (ms 916, El Escorial Library, Madrid, ff. 248v-249r; ms 5372, al-Ḥasaniyya Library, Rabat, pp. 23-24; ms 826, al-Ḥasaniyya Library, Rabat, ff. 97v-98r).

According to the extant sources, The Single Hour Line Method for the projection of rays is found in the 9th century in the writing of Abū Ma'shar (Balkh, *ca*. 787-*ca*. 886) (Lemay, 1995: vol. III, 549-550) and the same method for the prorogation is documented long after, in the 10th century in the *al-Madkhal* of al-Qabīṣ ī.

Nevertheless, The Single Hour Line Method for the prorogation possibly predates the 10th century. Al-Qabīṣ ī never assured to be its author, in fact he states that he collected the very essential of the astrological knowledge. It is difficult to clarify the source that al-Qabīṣ ī used for the section of prorogation since he did not mention it. In al-Qabīṣ ī's words: 'Since we have completed the explanation of what is known of the technical terms of the astrologers…'.

In light of all the above we should question ourselves which method really came first. Al-Bīrūnī shall help us to answer this matter: according to him in the *Kitāb al-qānūn* (p. 1394), 'this procedure [he means The Single Hour Line Method] for the projection of rays came from the procedure of prorogation'.

Although al-Bīrūnī does not specify what method of prorogation he refers, we may deduce that is The Single Hour Line Method for the prorogation because of its close similarity with The Single Hour Line Method for the projection of rays (see section 1.2 above).

Therefore, as indicated in the testimony of al-Bīrūnī, The Single Hour Line Method for the prorogation came out before, and then was applied to the technique of projection of rays.

The Single Hour Line Method for the prorogation was one of the most ancient procedures for the prorogation on the equator used in Islamic astrology, and it probably appeared in the first half of the 9th century or earlier before.

The Single Hour Line Method for the prorogation in al-Baqqār's book

1. Sources

The fourth chapter of the summary of astrology *al-Madkhal ilà ṣ inā'at aḥ kām al-nujūm* of the Eastern astrologer al-Qabīṣ ī has been arranged into fifteen sections, each one of them devoted to a different astrological matter. Al-Qabīṣ ī explains in the prorogation section (see section 1.2.1 above) The Single Hour Line Method for the prorogation.

Al-Baqqār does not quote the name of al-Qabīṣ ī, but he might use *al-Madkhal* as his source, because the passage, in which The Single Hour Line Method for the prorogation is described, is almost the same in both astrologers' writings and the existence of an al-Qabīṣ ī's book translation into Latin points out that *al-Madkhal* was known in al-Andalus.

2 Transformation

Al-Baqqār enters the computation of The Single Hour Line Method for the prorogation using the tropical degree of the indicator. Al-Baqqār argues that 'when the indicator is placed on the tenth or on the fourth house [it means, it is placed on the meridian], you add the number of years to the ascensions of the tropical degree of the indicator on the right sphere, and then you convert them into ecliptical degrees with a table of right ascensions. Wherever it falls on the ecliptic (on the sidereal sphere), the prorogation in that year will arrive there'.

Al-Baqqār speaks about 'the tropical degree' (*al-daraja al-ṭ abī'īya*) and about 'the sidereal sphere' (*al-falak al-dhātī*). These expressions do not appear in al-Qabīṣ ī's text. The introduction of 'tropical' (*ṭ abī'ī*) and 'sidereal' (*dhātī*) terms in al-Baqqār's book is really significant because this language is used by Western astronomers to distinguish between tropical and sidereal longitudes and it is often found in writings focusing on the trepidation theory (Samsó, 2001: 169-174; Díaz-Fajardo, 2001: 24-25; Comes, 2002: 130-131).

In medieval Arabic astrology, the expression *al-mabdā' al-ṭ abī'ī* refers to a longitude calculated from the vernal point and the expression *al-mabdā' al-dhātī*, to a longitude calculated from a star called The Head of Aries.

Andalusian astrology usually deals with sidereal positions and not tropical. Sidereal positions are computed from the position of a very specific star, which in an historical moment in the past was placed in front of the vernal point. Therefore, we might deduce that the position of the indicator which the astrologer prorogates is a sidereal position. However, the procedure of prorogation required the use of right ascensions, which are computed from a point of the equator placed at a distance of

90º from the vernal point corresponding to Capricorn 0º on the ecliptic (right ascensions in medieval tables). In this case, it is clear that the astrologer must work with tropical positions. That is why al-Baqqār mentions that the position of the indicators must be tropical when computing prorogation.

Furthermore, al-Baqqār ends the explanation of the computation with the following words: 'Subtract from the result the accession (*al-iqbāl*) motion or add to it the recession (*al-idbār*) motion. The prorogation for that year will finish at the resulting degree'. In this paragraph, there is a statement that does not appear in al-Qabīṣ ī's text: 'Subtract from the result the accession motion or add to it the recession motion'. Al-Baqqār is indicating the effects of trepidation theory on the celestial longitudes.

The theory of trepidation was an attempt to explain the constant motion of the equinoxes, known as the precession of the equinoxes. The followers of this doctrine believed that the celestial sphere made a first motion of accession (*iqbāl*) and a second motion of recession (*idbār*). During the motion of accession, a tropical longitude increase occurred as the vernal point went back, while during the motion of recession, there was a tropical longitude decrease as the vernal point went forward in the order of the zodiac signs.

* * *

The tropical longitude may contain a negative or a positive value of precession. By introducing these amounts in the formula, al-Baqqār obtained a sidereal longitude, that is, a longitude where precession is not present. Hence:

During the phase of accession:

Sidereal terminal point of the prorogation = $(\alpha_0^{-1} [\alpha_0(\lambda d) + Y])$ – value of precession

During the phase of recession:

Sidereal terminal point of the prorogation = $(\alpha_0^{-1} [\alpha_0(\lambda d) + Y])$ + value of precession

To obtain the terminal point of the prorogation, al-Baqqār achieved the mathematical operations using the tropical longitude, but for the astrological interpretation, he worked with the sidereal longitude that is measured on the circle of the zodiac signs. As al-Baqqār himself explains, 'sidereal longitudes must be used for astrological matters in which you have to verify the celestial influences' (Díaz-Fajardo, 2001: 24-25, 78-79).

First, al-Baqqār followed the Eastern tradition for prorogation computing. This tradition is showed in al-Qabīşī's text: al-Baqqār, likely following al-Qabīşī, added the ascension (α) of the longitude (λ) of the indicator (d) to the number of years (Y) ($[\alpha(\lambda d) + Y]$) and then, he searched for the inverse ascension (α^{-1}), i.e., the longitude that corresponds to the ascension of the sum.

Second, al-Baqqār adapted the method of prorogation to the Western astronomical context. This Andalusian-Maghribi tradition settles two kinds of longitudes: one tropical and another one sidereal. Al-Baqqār mentions that he worked with the tropical degree of the indicator and that the terminal point of the prorogation finishes in the sidereal sphere [the place where sidereal longitudes are measured].

Conclusions

Medieval Arabic astrologers took advantage of the available knowledge to carry out their trade: The Single Hour Line Method had a double function due to its use in the prorogation and the projection of rays. This relationship clarifies why some astrologers referred to two different practices as a single discipline with the following words, 'the science of prorogation and projection of rays (*'ilm al-tasyīr wa-maţārih al-ashi''a*)'.

Finally, the study of al-Baqqār's book illustrates the transmission of the astrological ideas in the Middle Ages. Al-Baqqār introduced a terminological feature in his text, which implies that the ruling astronomical practice in Western Islamic astronomy, the trepidation theory, was applied to an Eastern astrological procedure, The Single Hour Line Method for the prorogation.

THE ARTISANS OF ‘PLUS ULTRA’: PILOTS, CARTOGRAPHERS, AND COSMOGRAPHERS IN THE *CASA DE LA CONTRATACIÓN* IN SEVILLE DURING THE SIXTEENTH CENTURY[1]

Antonio SÁNCHEZ MARTÍNEZ
Department of Humanities: Philosophy, Language and Literature,
Universidad Carlos III de Madrid, SPAIN
ansanche@hum.uc3m.es; antosanmar@gmail.com

Abstract

In the context of the growing historiographical interest that is causing the world of Iberian science, especially among non-Spanish authors, during the Early Modern period after the Discovery of America, in this paper the author shows how it carried out the grand project of institutionalization of cosmography throughout the sixteenth century, from the Catholic Monarchs to Philip II. Through the inner workings of the House of Trade, the Indian Council, and the Academy of Mathematics this paper highlights how the Universal Monarchy and its conqueror slogan ‘Plus Ultra’ tried to encircle the Atlantic world first, and to dominate the New World later, by means of Cosmography, an essential science for the maintenance of the overseas Empire[2].

The aim of this paper is to demonstrate how the institutionalization of cosmography and navigation ended with the slogan Non Terrae Plus Ultra*, and led to the emergence of imperial heading* Plus Ultra *helped by the navigation of a* Mare Tenebrosum *(the Atlantic Ocean), and the delineation of the contours of a new world that began beyond the Columns of Hercules. This process was made possible by the establishment in Seville of the House of Trade in 1503 and the creation of scientific offices such as Pilot Major, master of making nautical charts or cosmographer. The ship that appears on the cover of the* Regimiento de navegación *(1606) by Andres Garcia de Céspedes across the pillars of the hero of Greek mythology highlights the Baconian premise of man’s dominion over nature, the knowledge gained through the conquest of the West Indies, and also the wishes of the Spanish Monarchy by taking advantage of the usefulness of scientific knowledge by joining the nautical experience and cosmographical theory.*

[1] I would like to thank the support of the FPU Grant Programme and the Project HUM2007-63267 funded by the Spanish Ministry of Science and Technology and the postdoctoral fellowship Alianza 4 Universidades.

[2] On this subject, the author of this paper has recently published a larger study. See Antonio Sánchez Martínez, “Los artífices del *Plus Ultra*: pilotos, cartógrafos y cosmógrafos en la Casa de la Contratación de Sevilla durante el siglo XVI”, *Hispania*, LXX (236): 607-632.

1. Since 1503, Spanish nautical and cartographic activity was organized in the House of Trade (*Casa de la Contratación*) in Seville. Its members offered classes in navigation, designed nautical tools and made maps while information from the Indies was centralized and systematized[3].

In 1508 was established the post of Pilot Major, devoted to draw nautical charts. The House created in this way its department of cosmography, with a school of navigation dedicated to training pilots and making maps. Pilot Major was the first scientific position of the House, and he should examine the navigators of the Indies, approve their instruments, draw and correct the charts and keep them secret. One of the most important tasks of the Pilot Major was the production of a model chart –called *Padrón Real*– that would reflect, with updated information, all exposed coastlines.

The establishment of the first pilot of the House has been considered the origin of the first technical school in Europe, where the development and application of scientific knowledge was led to improvements in ocean navigation. At the age of exploration, if the map had the virtue of opening the windows of the empire, navigation was the real eye of the kingdom.

2. The post of Pilot Major was assigned during the sixteenth century by Royal Decree, although the criteria for election depended on the appointment of the king or a sort of competitive examination. This latter procedure depended of an expert tribunal in cosmography, whose election was obtained first, a proposal of three persons to the Indian Council, where the fortunate was finally appointed. The political and scientific direction taken by the post of Pilot Major not only favoured the specialization of the sailors, but also saw increased the social status of a group of workers of the ocean who had not previously enjoyed any prestige.

What people could aspire to the position of Pilot Major and what were the conditions to qualify for it? The requirements were similar to those required to become a pilot. Often, candidates were experienced sailors in the art of navigation, but experience was not everything. Its expertise in maritime matters had calmed its experimental character in favour of the resolution of technical problems. These wise pilots should have the ability to unite theory and practice to discipline also the experience of young navigators. In addition, men were admitted for examination who were more than twenty-four, people who would not reveal the secrets of their trade, navigators with a minimum of six years experience in Indian and Atlantic navigation, and people of good habits and honest, Christian, and not foreigners, even when married to Spanish women. People previously excluded could not be admitted. Sometimes all these conditions were altered depending on the suitability and skill of the candidate. While Vespucci and some of his successors were foreigners, the court emphasized the importance of providing exclusively Spanish pilots for the Indian venture. The problem of treason was always present. The maps used for Atlantic navigation should not fall into foreign hands. The lack of training and perhaps the importation of new methods led the Spanish monarchs to offer these jobs to foreigners.

In 1519 was created the position of 'Master of making nautical charts'. Masters and cosmographers should make charts for the crossings to West Indies, after review and consideration of Pilot Major. Such maps could only be made by officers who had granted license. These permissions were the source of many of the disputes arising between 'officials' of the House. All they were trying to find an answer to the next question: who was prepared to make good charts? What was the interest of men who without possessing a license to make charts invaded the field of other authorized cartographers? What were the arguments dictating who should get permission to build charts and become a renowned cartographer, and who gave this credential?

In 1523 the mapmaker Diego Ribero was appointed cosmographer of the House. Thereafter, and until the creation of the Chair of Comography in 1552, the Pilot Major and the House's Cosmographer would be the two highest scientific positions to which any navigator could aspire.

In the House there were two kinds of cosmographers, some manufactured instruments and others were engaged in educational activities. Cosmography, guarded by men trained in Castilian universities and not at sea, exercised its power as the theoretical arm of navigation. The House's cosmographers with theoretical training had the ability to turn, which apparently were practical problems affecting only the pilots, in a case that should be resolved by universal laws. Only those who had learned in the classroom the Ptolemaic system of representation or the Euclidean geometry would be able to solve such problems.

Cosmography gained more reputation at the expense of pilots. Only the Pilot Mayor, an expert navigator, kept as much reputation as the House's cosmographers to control the experience of pilots. By the mid-sixteenth century, the House's

cosmographers with scientific training were graduates of the Faculties of Arts. These universities offered an education dedicated to geometry, mathematics and the study of the cosmos. Once they were part of the crown, their work consisted in solving different problems of navigation. The cosmography of the House became the servant of navigation. In other words, navigation without cosmography was blind and cosmography without navigation useless.

3. What aspects did cosmographers prioritize in the arduous task of improving navigation? House's cosmographers tried to optimize and reform the methods of celestial navigation traditionally used by pilots, even knowing the difficulties that it would imply against the conservatism of a routine office-based practice. Many of these cosmographers were the authors of famous regiments that guided the pilots at sea.

This wave of cosmographers between the thirties and the seventies witnessed the interest of the crown not only to dominate the Atlantic and control the New World, but also to carry out this control in safety conditions. In these decades new positions were created related to cosmography. In 1563 Alonso de Santa Cruz would be the first Cosmographer Major of the House, a new post that was the precedent of Cosmographer Major of Indies.

The House's cosmographers would make maps and instruments, and also would reinforce navigation and cosmography with theoretical knowledge. During these four decades the Spanish monarchy attempted to combine practical experience with scientific data of the theory. In the inner workings of the House this task would not be easy. The results would only be reflected in the cartographic representations of the new possessions.

4. In 1552, given the organizational needs with the massive influx of geographic information to Seville and as a result of errors in nautical charts, the Chair of Cosmography was created. This chair allowed the Pilot Major to leave his teaching assignments. Jerónimo de Chaves would be the first professor of cosmography. In general, this professor was always a reputable cosmographer with a long career in nautical and cosmographical issues.

The precepts of the Ordinances of 1552 had a strong scientific aspect. The office of Pilot Major would share authority with other positions and was not the only person responsible for approving charts and instruments made in the House. Henceforth, any cartographer and instrument maker should submit its production to the Pilot Major and the House's cosmographers to be accepted. The scientific work of the House would fall into the hands of three offices: the Pilot Mayor, the Professor of Cosmography and the Cosmographer responsible for making nautical charts and nautical instruments.

5. Since its establishment, the office of Pilot Major was destined to the production and updating of a standard nautical chart, the *Padrón Real*, but also to the transmission of knowledge for future navigators. Education and training of pilots was one of the primary tasks for which this position was created. Men who wanted to be navigators should know the basic principles of celestial navigation, how to handle the quadrant and the astrolabe and, of course, reading a nautical chart correctly. The House combined from 1508 the urgency of the crown for having qualified pilots with the necessary training to discover new riches and transport them safely to Seville. At the beginning of the century, the House was the only school of nautical education in Europe, except for the one Henry the Navigator inaugurated in Sagres in the fifteenth century. Under the protection of the court, the school of Seville represented one of the first scientific institutions dedicated to education by the State in the early modern world. The House was also a school of geographical and cosmographical studies that formed the scientific basis of the expeditions to the New World. The court, the Indian Council, the Pilot Mayors and cosmographers joined forces for pilots to acquire practical and theoretical knowledge.

The House was the most appropriate place for the training of seamen. To become a pilot it was only necessary to have interest in learning the trade. However, for safety and convenience reasons, discriminatory measures began to be introduced from the twenties, especially against foreigners, in order to retain the exclusive control of Indian trade. In 1527 the king ordered Cabot to not examine foreigners and, among other measures, candidates should take a nautical chart on which their position, the courses, and most important ports and lands were shown. The measures against foreigners were not always implemented and they were altered according to the interest of the crown. The applicants from other kingdoms should be married to a Spanish woman and domiciled in Castile.

6. The world of navigation was during the Age of Exploration a very influential space and an inexhaustible source of possibilities. Any activity related to the Atlantic, even the prosperity of the empire, depended on the pilots and adjacent sciences. The navigators were no strangers to the new opportunities offered by this old job. Pilots and cosmographers of the House fed Europe with first-hand information about America. They were the artisans of a new world. Only they, theoretical and practical men, had the ability to adapt ancient navigation techniques from the Mediterranean and old cartographic models to a new geographic reality. Their pragmatism to the problems of measurement, calculation and representation of spaces made them builders of a new scientific, technological and conceptual framework. The compass, measurement and representation of the conquered territories were as important as the occupation itself, for the definition of territorial sovereignty was behind the imperial slogan 'Plus Ultra'.

The activity of these new artisans of the world was not independent of the administrative needs of an expanding empire. The creation of their positions and the development of their disciplines assembled both bureaucrats and intellectuals for the same cause: the dominion of the New World. Navigation, cartography and cosmography were subjects of power, bureaucratic and institutionalized, sciences that founded the Universal Monarchy.

Spanish imperial science related to geographical discoveries was dominated by a utilitarian conception of knowledge. Undoubtedly, adequate knowledge was useful knowledge, but not only. In some cases, this science was also concerned with revealing certain secrets of nature that directly affected its development. Some cosmographer who worked for the crown developed an unprecedented epistemological approach in the search of a causal analysis of observed phenomena. The problem of magnetic declination, for example, was one of those secrets of nature. But unlike the new natural philosophy of the seventeenth century, the study of occult forces during the previous decades was led by often discredited artisans, for which the experiment was not the end product of their work, but the starting point. It was necessary to experience the effects of magnetic declination before analyzing its causes. The experience was the essential support to be able to carry out useful science in sixteenth-century Spain, an experience that should be disciplined, educated and considered by the theory. The virtues of experience and theory built a more measurable and visible world, in short, a more vulnerable world.

FROM DENMARK TO ITALY: FRANCESCO PATRIZI'S RECEPTION AND CRITICISM OF TYCHO BRAHE'S GEO-HELIOCENTRIC PLANETARY SYSTEM

Matjaž VESEL
Institute of Philosophy,
Scientific Research Centre of the Slovenian Academy of Sciences and Arts, SLOVENIA
matjaz.vesel@guest.arnes.si

Abstract

In 1588 Tycho Brahe published a book on the comet of 1577 De mundi aetherei recentioribus phaenomenis*, which contained the first published account of his new geo-heliocentric planetary system, with all the planets revolving around the Sun and the Sun in turn revolving around the stationary Earth. In the Tychonic system the orbits of Mars and the Sun intersected, which was made possible by replacing the traditional solid, real spheres with the fluid heavens. Three years later in Ferrara (1591) the first note on the Tychonic system appeared in a published book. Francesco Patrizi briefly described it in his* Nova de universis philosophia *at the end of his overview of the history of astronomical systems. In my paper I will investigate Patrizi's criticism of astronomy (according to him* all *astronomers, including Tycho Brahe, believe that the stars are fixed in the heavens* sicut nodi in tabula*), and how it happened that Patrizi completely overlooked one of the crucial achievements of Tycho Brahe's book (fluidity of heavens).*

In 1588 Tycho Brahe published a book on the comet of 1577 entitled *De mundi aetherei recentioribus phaenomenis*, which contained the first published account of his new geo-heliocentric planetary system, with all the planets revolving around the Sun and the Sun (as well as the Moon) in turn revolving around the stationary Earth. In his system the paths of Mars and the Sun intersected, which was made possible by replacing the traditional solid, real spheres or orbs with fluid heavens, in which the orbs are nothing more than geometrical boundaries.[1]

[1] On the elimination of solid celestial orbs or spheres from astronomy, see M. A. Granada, *Sfere solide e cielo fluido: Momenti del dibattito cosmologico nella secunda metà del Cinquecento* (Milano: Guerini e associati, 2002), and *El debate cosmológico en 1588: Bruno, Brahe, Rothmann, Ursus, Röslin* (Naples: Bibliopolis, 1996); M. P. Lerner, *Le monde des sphères*, vol. II (Paris: Les Belles Lettres, 2008²).

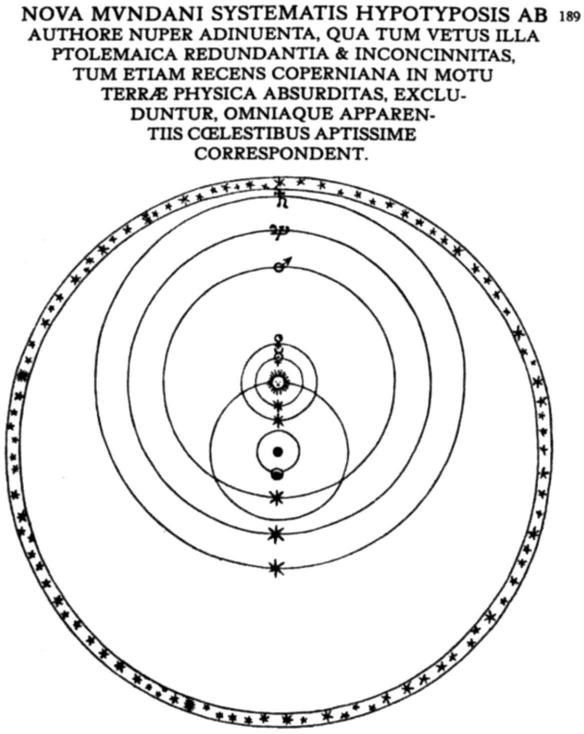

Fig. 1: Brahe's geo-heliocentric system as depicted in his *De mundi aetherei recentioribus phaenomenis* (Uraniborg, 1588), p. 158.

A few copies of the printed book were sent to some of the leading astronomers throughout Europe, some were offered for sale at the Frankfurt book fair, but most copies were stored unbound.

Three years later, in 1591, the first note on the Tychonic system appeared in a published book. Francesco Patrizi, an idiosyncratic Neoplatonic philosopher, briefly described it in the fourth part of his *Nova de universis philosophia*, published in Ferrara. Here's what he says:

> *If I am not mistaken, there is still alive a Dane by the name Tycho Brahe* (Tychon Brae)*, who on the basis of his own observations of the universe has established a hypotyposin different from Copernicus's. He places the eighth and three superior* [orbs] *in the same order [as Copernicus], but eccentric. But he says that the orb of Mars intersects the orb of the Sun in two places. Above the Sun he places Mercury and next Venus in two small circles, one bigger and the other smaller, which both revolve around the body of the Sun and the orb of the Sun, and both intersect the orb of the Sun in two places. In the centre of the universe he places the Earth, around which is the orb of the Moon, which is enclosed by the orb of the Sun, but which the orbs of Mercury and Venus do not enclose.*[2]

Before I give a fuller account of Patrizi's views on astronomy in general and on Tycho Brahe's in particular, a few words about his scholarly career and work are in order.[3]

Patrizi was born on the island of Cherso off the Dalmatian coast in 1529. In 1547, four years after the publication of Copernicus's *De revolutionibus orbium coelestium* and around 50 years after Copernicus studied there, he enrolled as a student of medicine at the University of Padua. He soon discovered the subject was not for him and switched to studies in philosophy and mathematics. Despite the predominantly Aristotelian, even Averroist orientation of the Padua *Studio*, he soon discovered Platonic and Neoplatonic philosophy, and became interested in the mystical, Chaldaic, Arab, and Hebrew

---

[2] Nova de universis philosophia, IV, 12 (91r). I will subsequently refer to *Nova de universis philosophia* as NUP.

[3] For a fuller account of Patrizi's life, works, and career, see for example the online entry by Fred Purnell in the *Stanford Encyclopedia of Philosophy* (http://plato.stanford.edu/entries/patrizi/). There is a nice outline of Patrizi's cosmology by M. A. Granada, "New Visions of the Cosmos", in J. Hankins, ed., *The Cambridge Companion to Renaissance Philosophy* (Cambridge, Mass.: Cambridge University Press, 2007), pp. 275–278.

traditions and in Hermetic writings. He studied the works of Plato and Aristotle and of the most interesting Renaissance Neoplatonic thinkers, such as Marsilio Ficino, particularly his doctrine of the renewal of *prisca theologia*, a philosophical project of renewal of Christianity.

The first of his two major philosophical works appeared in its entirety in 1581 in Basel.[4] *Discussionum peripateticarum libri decem*, as the book was called, was a fierce attack on Aristotle and peripatetic philosophy. It can be characterized as the negative part of his project. Ten years later, in 1591 he provided his positive part, his most significant philosophical work being *Nova de universis philosophia*.[5] The book is divided into four parts: *Panaugia*, *Panarchia*, *Pampsychia*, and *Pancosmia*. The fourth book, *Pancosmia*, is subtitled "Principles and Constitution of the Corporeal World," and is therefore extremely interesting from the perspective of the history of science.

Patrizi's criticism of astronomy: astronomers believe that the stars are fixed in the heavens *sicut nodi in tabula*

Patrizi mentions Tycho Brahe's geo-heliocentric system in Book 12, "On the Number of Heavens", of *Pancosmia*, wherein he presents some kind of history of astronomy from Thales to Tycho Brahe, written from the perspective of the number of celestial spheres astronomers used to explain celestial phenomena. Patrizi's overview begins with Thales and the Pythagoreans, continues with Ptolemy and some Arabic astronomers and philosophers (Thabit ibn Qurrah, Averroes, and al-Battani), and finally comes to the "modern era".

"In our time three new astronomical theories have arisen, very different from those of the ancients and very different from one another," he says. First, there is Copernicus, who revived the teachings of Aristarchus of Samos. He "overturned the whole astronomy of the ancients and the whole order of the universe". The second theory is that of two men from Verona, Giovanni Battista della Torre and Girolamo Fracastoro, who brought back in memory and use the old homocentric spheres, increasing their number to 77.[6] And finally there is the passage, quoted above, which describes Brahe's system.

After this short overview of the history of astronomy, Patrizi continues with the following argument, which is very representative of his overall mode of reasoning in *Nova de universis philosophia* –and in his other works.

It is necessary that everything that was mentioned is either true or false or that some part is true and some part is false.

It is impossible that everything is true since all those astronomical theories and systems are completely mutually incompatible. It is therefore more probable that all of them are false. Why? Patrizi replies: because they are all monstrous. Why? The astronomers claim that heaven is a simple body. How can it happen that there is so much diversity in this simple body?

But if some theories are true and some theories are false, one has to determine which theory or theories are true. Now, if one looks at the tables and ephemerides of ancient astronomers, he reasons, one realizes that they do not adequately respond to recent observations; they are out of date. This means that ancient astronomy is false. On the other hand, modern astronomers make their calculations on the basis of Copernicus's hypotheses and claim that they have furnished true tables. But according to the "new observer of the stars", Tycho Brahe, even those are false and defective and he himself has set out to improve them.[7]

Patrizi is obviously perplexed faced with all these different, mutually exclusive astronomical theories and the ever increasing number of celestial spheres that astronomers used and still use in order to "save appearances". His conclusion, which he does not explicitly write down but which is implicit in his reasoning, is absolutely clear: *all*, I repeat, *all* astronomical systems are in error, they are all *deliria* (or *deliramenta*) and *monstra*, and the most monstrous of them all are those of Copernicus and Tycho.

Why is that so? What is the ultimate reason that lies behind astronomy's "innumerable delusions", "monstrosities", and "chimeras", and which in the end produced "a whole new chaos"?

---

[4] Volume I of *Discussiones* was first published in Venice in 1571.

[5] See M. Muccillo, "La dissoluzione del paradigma aristotelico", in C. Vasoli, ed., *Le filosofie del Rinascimento* (Milan: Mondadori, 2002), pp. 506–533.

[6] See NUP, IV, 12 (91r). It seems to me that Patrizi had read Fracastoro's dedication to Paul III from his *Homocentrica* (Venice, 1538), where he mentions Ioannes Baptista Turrius as somebody who revived homocentric astronomy. Patrizi does not mention Givanni Battista Amico, who made the same attempt two years earlier in *De motibus corporum coelestium iuxta principia peripatetica sine eccentricis et epicyclis* (Venice, 1536).

[7] See NUP, IV, 12 (91v).

First: the general tendency to "save appearances". Second: the specific assumption, which was, and according to Patrizi still is, accepted by *all* astronomers, including Tycho Brahe, "that the stars are fixed in the heavens like knots or nails in a plank", that is to say, that the stars are fixed in solid, real heavenly orbs.

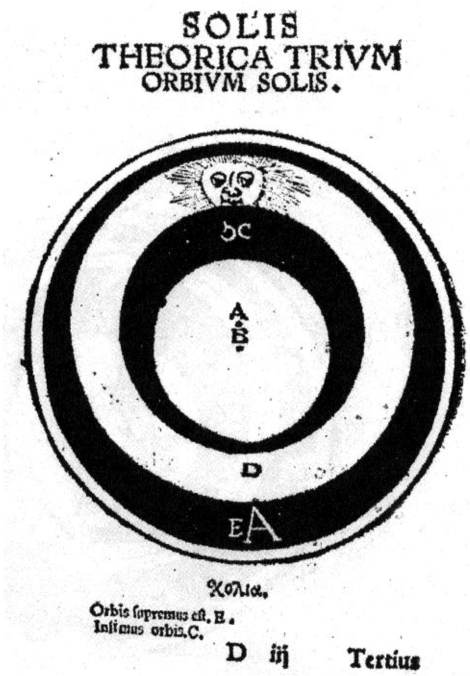

Fig. 2: Model of real, solid orbs for the Sun (*theorica solis*) from Peurbach's Theoricae novae planetarum, first published in 1472. Between 1472 and 1653, more than fifty editions of Theoricae novae appeared, prompting a massive number of commentaries to be produced.

This assumption, and this assumption alone, forced astronomers –and it is important to note that Patrizi claims that this assumption was the invention of astronomers–[8] to adopt various flawed theories:

> *All those* [astronomical theories and systems]*, these two* [Copernicus's and Brahe's]*, and the old ones derive from that one position: that the stars are fixed in the heavens like knots or nails in a plank. Because of this fixation they first invented eight spheres and since those were not sufficient to save appearances they added innumerable deliraments and monstrosities, which in the end produced a complete perturbation of the whole world, like a whole new chaos.*[9]

In sum: Patrizi is convinced that *all* astronomy suffers from an erroneous belief in the fixation of the stars in the heavens, that this illness brought about a chaos and monstrosity in the universe, and that the most monstrous universes were those conceived by Copernicus and Tycho Brahe, who were both firm believers in the doctrine of the fixation of the stars in the heavens.

---

[8] See NUP, IV, 12 (90v).

[9] NUP, IV, 12 (91v). Patrizi's claim that *all* astronomers believed that stars are attached in solid orbs is in my view additional proof that before the late 1570s and especially 1580s, this was a widespread, common astronomical assumption. See also P. Barker, "The Reality of Peurbach's Orbs", in P. J. Boner, ed., *Change and Continuity in Early Modern Cosmology* (New York: Springer, 2011), pp. 7–32, who, after examining the published commentaries on Peurbach's *Theoricae novae*, and commentators on Sacrobosco's *Sphaera*, came to the conclusion that, with the exception of Prieras, all these commentators follow Peurbach in treating the celestial orbs as real and that there may be historical reasons for Prierias' reservations.

How did Patrizi completely overlook one of the crucial achievements of Tycho Brahe's book?

Since there is a very clear statement about the elimination of solid spheres and their replacement by fluid heavens in Chapter 8 of Brahe's book,[10] one wonders how it happened that Patrizi overlooked it. Did he read Brahe's *De mundi aetherei* at all?

In their excellent edition of Kepler's *Apologia pro Tychone contra Ursum* N. Jardine and A. Segonds suggest that Patrizi's note on Brahe's system "depended on a lecture or at least on a direct consultation of Chapter 8 of *De mundi aetherei*". They underline his use of the term *hypotiposis* in describing Brahe's system, which is the same word as appears on the page with the figure of the system,[11] and they conjecture that Patrizi's note is nothing other than a "pure and simple description of Brahe's figure" and that he simply did not take into account the details which Brahe gave on the next page about the intersections of the spheres.[12]

In my opinion, it would be extremely strange for Patrizi to have access to Brahe's book, to take into account the strange figure with intersecting orbs, but to dismiss Brahe's explanations of this strange feature of his system on the next page. I closely considered this puzzling situation and from what I have been able to discover so far, I can say that N. Jardine and A. Segonds are partly wrong and partly right. Patrizi did not have direct access to the book and its content, but nevertheless described Brahe's system on the basis of the figure therein. How was that possible?

When Brahe invented a new system of the world he was eager to win general approval and sent the book to his usual correspondents. The task of distributing the book was partly bestowed upon one of his collaborators at Uraniborg, Gellius Sascerides.[13] In 1588 Sascerides departed for Padua via Germany and Switzerland. In 1590, while attending Frankfurt's annual book fair, he received a copy of *De mundi aetherei* with instructions from Brahe to send it forward to the famous Italian astronomer Giovanni Antonio Magini, teacher of mathematics at the University of Bologna. Sascerides went back to Padua and duly sent the book to Magini.[14]

After the publication of Patrizi's *Nova de universis philosophia* in 1591 Sascerides somehow found out about Patrizi's account of Brahe's system. We do not know how that happened, if he bought the book, read it in some library, or just heard about it.

What we do know is that on 12 March 1592 Gellius wrote to Patrizi. I have so far been unable to determine whether his letter to Patrizi is extant –it seems that it is not– and what its exact content was. I also do not know whether he wrote to him on his own initiative or was asked to do so by Tycho Brahe. It seems to me more probable that Brahe was behind it. But from Patrizi's reply to Sascerides, written in Ferrara on 25 March 1592, which is extant[15] –a reply that Alain Segonds and Nicholas Jardine overlooked–, one learns that Sascerides (or more probably Tycho Brahe himself) was very upset because of Patrizi's misrepresentation of Brahe's astronomy. From that letter it is also clear that Gellius wrote to Patrizi:

> *that in Book 12 of Pancosmia he said something about his* [i. e. Brahe's] *astronomy, which cannot be read at all in his books, and that there are written down exactly opposite opinions about the heavenly orbs and the hardness of the heavens.*[16]

Favaro, *Carteggio inedito di Ticone Brahe, Giovanni Keplero e di altri celebri astronomi e matematici con Giovanni Antonio Magini tratto dall'Archivio Malvezzi de'medici in Bologna* (Bologna: Zanichelli, 1886), p. 13. Brahe thanked Gellius Sascerides in October 1590. See T. Brahe, *Opera omnia*, ed. by J. L. E. Dreyer and E. Nystrøm (Copenhagen: Gyldendal, 1913–1918), VII, p. 278.

[15] Patrizi's letter to Sascerides was published in a critical edition of his letters and unpublished works, prepared by D. A. Barbagli, in Francesco Patrizi da Cherso, *Lettere ed opusculi inediti* (Florence: Instituto nazionale di studi sul rinascimento, 1975), pp. 79–82. See also P. Rossi, "Sfere celesti e branchi di gru", in P. Rossi, *Il tempo dei maghi: Rinascimento e modernità* (Milano: Raffaello Cortina, 2006), pp. 185–225.

[16] Patrizi's letter to Sascerides, 25 March 1592, in Francesco Patrizi da Cherso, *Lettere ed opusculi inediti*, p. 80.

Secondly, Sascerides excerpted these thoughts from Brahe's writings and sent them to Patrizi.

In the rest of his letter to Sascerides, Patrizi explains how he learned about Brahe's astronomy. When he heard about the novelties of Tycho's astronomy he tried to get hold of them. He tried to purchase the book but was not successful. Then he heard from Giovanni Francesco Pinelli that Tycho had sent one copy to Magini.[17] Patrizi wrote to Magini, asking him for a copy or at least for a description of the new system. Magini sent Patrizi some of Sascerides's letters to Magini and the "*hypotiposin* of the universe outlined in orbs". From these he deduced what is written in Book 12 of *Pancosmia* about Tycho's new astronomy. In the letter Patrizi then promises Sascerides that he will compare his description of Brahe's system with the papers he has now received. If he realizes that he was mistaken, he will recant and restore Brahe's praise. But at the moment he can do nothing. He has sent a part of his books and papers to Rome, where he has been summoned by the Pope. And he wants Tycho to be informed of all this.

It is obvious from this letter that Patrizi had not read nor seen Brahe's book, and that he had drawn on Sascerides' letters to Magini that had been forwarded to him. These letters should, according to what Sascerides wrote to Patrizi, contain Sascerides' description of Brahe's new astronomy from Sascerides' letters to Magini and Magini's copy of the figure of the new *hypotiposin*.

Sascerides' letters to Magini (together with Brahe's letters to Magini and Magini's to Brahe) are extant and were published by A. Favaro, in *Carteggio inedito di Ticone Brahe, Giovanni Keplero e di altri celebri astronomi e matematici con Giovanni Antonio Magini,*[18] but we do not know exactly which letters Magini sent to Patrizi. What I have been able to learn from this correspondence thus far is the following. There is relatively little talk of Brahe's system *per se*. In one of Gellius' letters to Magini the system is called *dyatiposin* and not *hypotiposin*. Brahe informs Magini that he has been plagiarized by Ursus. Magini praises his system, but says he would prefer if the orbs of the Sun and Mars did not intersect.

This laudatory comment was enough for Tycho. In November 1591 he wrote to John Craig about his relationship with Magini in order to prove that he had followers even outside Germany:

> *I will add some extracts from the letters of this most illustrious and excellent mathematician, Giovanni Magini, so that you might see that the excellent minds in Italy, as* [in Germany]*, have agreed with our theses and entirely approved them.*[19]

As we have seen, exactly the opposite was the case with the other excellent mind in Italy, philosopher Francesco Patrizi, who had a very low opinion of Brahe's system and of all of astronomy, for that matter. But Patrizi soon had some other problems to think of. His *Nova de universis philosophia* upset not only astronomers, but stirred quite a controversy with critics from theological and philosophical quarters as well. Despite the fact that he started lecturing in Rome in May, 1592, his *Nova de universis philosophia* came under investigation and was finally put on the Index of Prohibited Books "until corrected" in 1596. It comes as no surprise that Patrizi, despite his promise, never revised his views on Brahe's astronomy. He had bigger concerns. He spent the last years of his life teaching Platonism, passing away in 1597 while still engaged in defending his controversial work.

* * *

[17] I am a little bit puzzled by M. Bucciantini's claim, in *Galileo e Keplero: Filosofia, cosmologia e teologia nell'Età della Controriforma* (Torino: Einaudi, 2007), p. 38, and n. 69, that Pinelli himself received a copy of *De mundi aetherei* from Brahe. See also Brahe's letter to Johannes Camerarius, 21 October 1590 (TBOO, VII, p. 276). The book is listed in Pinelli's library as "Thiconis Braeae phenomenae, Uranibirgi 1588". While it is very probable that Patrizi asked Pinneli about *De mundi aetherei* before fall/winter 1590, when it should have arrived at Pinelli's library, and who at the time of his inquiry was therefore redirected to Magini, who received it sometime in the first months of 1590, it is not clear – at least at first sight – why Brahe, who obviously had sent two copies to Italy, in a much later letter to Kepler, 19 December 1599 (TBOO, VIII, pp. 206–207), referred only to the copy sent to Magini: "MAGINUM Italum nunquam existemarim tale quid affectasse. Quod si fecit literis propria manu ad me datis, quibus se illam Hypothesin ex libro nostro secundo de Aethereis Phaenomenis primum perspexisse, sibique apprimere placere, modo Martis orbis Solarem transire posset (putavit enim ex vulgata sententia reales esse in coelo orbes) fassus est, contraria admisit. A MAGINO vero, si qui alij huius speculationis conscij sunt, hac occasione habuerunt, inter quos etiam est Francisus Patricius, qui eius mentionem in erudito alias de nova Philosophia Volumine facit, is quidem meam esse expresse asserit, sed eam ita pervertit, et per ignorantiam male accomodat, et contra mea ipsius postulata et assumpta eam coinquinat et insectatur, ut plurima isthic ex ipsius relatione apposita pro meis non agnoscam, quod etiam publice protestabor." N. Jardine and A. Segonds, *La guerre des astronomes*, vol. II/2, p. 433, interpret this passage in the sense that Brahe at that time knew only of one copy of his book in Italy, the one he had sent to Magini. Since Brahe sent one copy also to Pinelli, it seems to me that it is more likely that Brahe's stress here is not on the one and only existing copy of his book in Italy, but on his conviction that Magini, who still believed in the reality of celestial orbs, was the ultimate source of Patrizi's misinterpretation of Brahe's astronomy.

[18] Cf. n. 15 above.

[19] TBOO, VII, p. 315.

This is not, of course, the end of the story. As it is well known, Brahe decided –almost a decade after the publication of Patrizi's *Nova de universis philosophia*– to strike back or, to be more precise, he delegated the job of replying to Patrizi to Johannes Kepler, who did so in his manuscript *Apologia Tychonis contra Ursum*. I will analyse this part of the story, which from the perspective of historical epistemology is perhaps even more intriguing than the part analysed so far, in a forthcoming article. My contention is that in order to achieve a historically and epistemologically adequate understanding and assessment of the situation, we should take a look at it from two perspectives, astronomical or, even better said, astronomical-philosophical (represented by Kepler) and philosophical (represented by Patrizi).

THE BATTLE OF THE ASTRONOMERS. JOHANN ADAM SCHALL VON BELL AND FERDINAND VERBIEST AT THE COURT OF THE CELESTIAL EMPERORS

Stefano SALVIA
Università di Pisa, ITALY
stefano.salvia@tiscali.it

Abstract

My talk will focus on the two most outstanding figures among the Jesuit missionaries in 17th-century China: Johann Adam Schall von Bell (1591-1666) and Ferdinand Verbiest (1623-1688). In 1619 von Bell reached Macao, bringing some telescopes along and translating European mathematical, astronomical, and optical works from Latin to Chinese.
Von Bell aimed at introducing the telescope into Chinese astronomy, traditionally based on naked-eye observation and calculation. In 1634 he started a correspondence with the last Ming Emperor, Chongzhen (1611-1644), describing the many useful applications of the telescope.
With the advent of the Qing dynasty, von Bell became counselor of the new Emperor, Shunzhi (1638-1661), as well as Head of the Mathematical Board and Director of the Imperial Observatory. Verbiest was called in 1660 to assist von Bell in his project of reforming the Chinese traditional calendar.
The political situation changed dramatically in 1661, with the Empire ruled by four regents who were hostile to the Jesuits, as much of the Chinese mathematicians at the Observatory. What followed was not just a conspiracy against the Jesuits, but a sort of "Kulturkampf" raised by the most conservative side of the Manchu regime, which regarded the Europeans and their increasing authority as a threat for the Empire.
I want to discuss the famous contest between the Chinese astronomer Yang Guangxian (1597-1669) and the Jesuit mathematicians, which lasted from 1664 to 1669. Behind the scenes of a public competition to compare the merits of European and Chinese astronomy, a dangerous game was played at court, which involved science, technology, philosophy, power, credit, patronage, personal rivalry, and luck.
The contest was finally won by Verbiest, who succeeded to von Bell as Head of the Mathematical Board and became a close friend of the new Emperor, Kangxi (1654-1722), teaching him geometry, philosophy, and music. He translated Euclid into Chinese and in 1673 he rebuilt the Observatory according to the European standards.

The very first generation of Jesuit missionaries who went to China after Matteo Ricci's (1552-1610) death was made by scientists belonging to Christoph Clavius' (1538-1612) entourage at the Collegium Romanum. Ricci himself was one of Clavius' pupils, who were regarded at that time as the most brilliant mathematicians and astronomers of the Company. One must mention people like father Johann Terentius Schreck (1576-1630), who had attended Galileo's lectures in Padua between 1603 and 1604 and was elected *academicus lyncaeus* together with his former master in 1611, before joining the Company. Schreck and his confrere Johann Adam Schall von Bell (1591-1666) were both in Rome when Galileo, on May 18, 1611, was invited by Clavius to discuss his telescopic observations.

Von Bell was the main prosecutor of Ricci's missionary action in China. Born as an individual adaptation strategy, the "enculturation" practice became the Jesuit manifesto in the Far East. Unlike the Franciscans, who had formed some small, isolated communities in the poorest and most peripheral regions of the Empire, the Jesuits soon realized that speaking the language of the exact sciences was the only way to overcome the local prejudices against the Europeans and their culture. If they wanted to be accepted by the highest ranks of the Chinese society, they had to be recognized as part of the intellectual and political elite of the Empire. Already in his later years, when he finally managed to enter Beijing and to establish the first direct contacts with the Imperial Court, Ricci made official requests to his superiors about the necessity of supporting his mission with the best intellectual resources available at the mathematical school of the Collegium Romanum.

Between April and July, 1619, von Bell, Schreck, and Nicolas Trigault (1577-1628) reached Macau with over 20 newly recruited Jesuit missionaries, bringing some Galilean telescopes along, as well as many other scientific instruments. Probably the "Dutch glasses" had already been introduced in China by Italian, Portuguese, and Dutch merchants since 1608-1610, but the use of the telescope as an instrument is clearly attested only after von Bell's arrival. While in the West the Copernican debate was turning into a broader cultural, religious, and even political struggle, von Bell and Schreck were translating European mathematical, astronomical, and optical works previously approved by the Company from Latin to Chinese, as well as several textbooks on mathematics, engineering, medicine, and astronomy from Chinese to Latin. In 1626 von Bell wrote a treatise both in Latin and Chinese on dioptrics and the principles of telescope-making. His Biography of *Western Astronomers* (1640) was the first Chinese text written by a Jesuit that explicitly mentioned Galileo and his scientific achievements, providing a Mandarin transliteration of his name.

Since 1629 von Bell and his closest collaborators, like the Belgian father Jean-Nicolas Smogolenski (1610-1656), became court astronomers. They aimed at introducing both the Galilean and the Keplerian telescope into the practice of Chinese astronomy, traditionally based on naked-eye observations (helped by dioptres, alidades, and grids) and on measuring or calculation devices which were quite similar to the Western ones, like sundials, quadrants, sextants, armillary spheres, and celestial globes. Smogolenski is also known for having introduced the Western methods of predicting solar and lunar eclipses on the basis of Copernican ephemeredes, provided that they were regarded just as hypothetical and useful mathematical tools, without any commitment about their cosmological value.

However, the Chinese astronomers made a very limited use of the telescope until the 1680s, only to observe phenomena which were otherwise impossible to detect, like those described in the *Sidereus Nuncius* (1610). Furthermore, according to them, objects like sunspots had already been observed in China some centuries before, looking at the solar disc at dawn and sunset, as well as the stellar nature of the Milky Way had already been supposed. On the contrary, the first military use of the telescope is attested in 1635, during one of the by then frequent wars between the Imperial Army and the anti-Ming coalitions, while its presence on war and cargo ships is very rare.

It is very hard to establish when telescopes started being produced directly in China, without assembling *in loco* their components once they had been imported from Europe. One must remind that there was a very long tradition of lens-making in the country, dating back to the 13th century at least. Most of the Chinese magnifying lenses were made from rock crystal, which was very abundant in the mines of the South. As in the case of their Western medieval and early modern counterparts, these lenses were usually convex, because concave lenses were much more difficult to cut and to polish with high precision.

The Chinese craftsmen who produced such lenses were not opticians in a proper sense, but rather highly specialized glass-makers, gem-cutters, and jewellers. What is sure is that starting from the second half of the 17th century, under the new Qing dynasty, some of them began to work directly for the Jesuit astronomers and for the Imperial Court, producing the first exemplars of Chinese telescopes with bamboo tubes, rock crystal lenses, and decorated paper. We know from the registers of the European trade companies of the time that they belonged to a small community of excellent artisans. Being instructed by the Jesuits in the most recent developments of optics and instrument-making, they were able to read Latin and to speak Spanish, Dutch, and French, since they were agents of the Western companies.

In 1634 von Bell started an official correspondence with the last Ming Emperor, Chongzhen (1611-1644), describing the useful applications of the telescope in astronomy, navigation, military surveying, and geodesy, as well as the importance of the scientific novelties introduced by the Jesuits for the improvement of Chinese technology and the advantages offered by many other recent instruments, like the microscope, the analytical compass, the nocturnal watch, and the first models of mechanical clocks. Von Bell's attitude towards the Emperor was not so different from Galileo's one towards the Venetian Doge or the Grand Duke of Tuscany. Both in the Celestial Empire and in early modern Europe scholars could only be courtiers and the liberal arts largely depended on a very unstable patronage system, based on personal relationships and political contingencies. Moreover, even if some Jesuits (not all the missionaries) enjoyed the same privileges of other Han dignitaries in the Forbidden City, they could not share with them the same social status and prestige, simply because they were foreigners: tolerated, appreciated, but not Chinese.

With the advent of the Qing dynasty in 1644, the political scenario seemed to be more favourable for the Jesuits, at the very beginning, despite the fact that some of them had served Chongzhen as court astronomers. The new Manchu rulers must consolidate their power over the Empire, after many decades of revolts and conspiracies against the previous Ming domination. At the same time, they had to confront the increasing colonial pressure of England, France, and the Netherlands, while the military and political influence of Spain-Portugal was rapidly declining, especially after the end of the Thirty Years War. Being more and more isolated from this point of view, the Jesuit missionaries soon became part of a long-term political design of the Manchu elite. From the one hand, the Western "enculturers" must be put under the direct control of the Court, given the useful scientific-technological innovations they might bring to the Empire. On the other hand, their missionary action must be somehow neutralized through assimilation and political involvement in the State affaires to preserve cultural identity and traditions of the Chinese society.

Von Bell became the trusted counsellor of the new Emperor, Shunzhi (1638-1661), who created him mandarin, Head of the Mathematical Board, and Director of the Beijing Ancient Observatory, being charged of its restoration after a long period of decay. His position enabled him to procure special permission for the Jesuits to build their churches and to preach throughout the Empire. The Flemish Jesuit mathematician Ferdinand Verbiest (1623-1688), arrived in Macau in 1659, was called in 1660 to assist von Bell, mainly in his fundamental project of reforming the Chinese traditional calendar to make it compatible with the Gregorian calendar and with the most recent European acquisition in astronomy.

The Chinese traditional calendar had a very long history, dating back to the second millennium BC, with many reforms occurred in the meantime. It was a lunisolar calendar, made of 12 regular months which were alternatively 29 and 30 days long, originally with an additional day added from time to time, to catch up with drifts between the calendar and the actual moon cycle. Intercalary months were arbitrarily added at the end of the year. Between the 5th and the 2nd century BC progress in astronomy allowed the creation of calculated calendars, where intercalary days and months were set according to precise rules. Apart from minor modifications, the Chinese calendar remained the same until the 17th century: the solar year was made of 365 ¼ days, as in the Julian calendar of Rome, along with a 19-year (235-month) Rule Cycle, known in the West as the Metonic cycle. The year began on the new moon preceding the winter solstice, and intercalary months were added at the end of the year.

In 1645 von Bell introduced the calculation of the true motion of the sun and the moon with sinusoids, according to the common procedures of European astronomy. The main problem was the discontinuity in the annual motion of the sun across the different signs of the Zodiac that resulted from such a non-Gregorian system. The reform of the calendar was not just a question of better or worse instruments, more or less advanced calculations, and discussions among experts with different opinions. It was a very crucial point, since the Confucian philosophy saw an intimate connection between the astronomical order, the natural order, and the socio-political order, with the Emperor as the unifying principle and the divinized mediator among all the three ontological and cosmological levels, as the highest terrestrial being and the lowest celestial one.

Astrology had a fundamental role in Chinese culture, since any change in the heavens was supposed to have immediate consequences on the earth, and vice versa. Astral configurations had direct influence on psycho-physical constitutions and moral dispositions, as well as on health and stability of the collective body, while vicious inclinations might affect the pre-established harmony both of nature and society. The main task of a court astronomer-astrologist was precisely to provide a correct interpretation of this mutual interaction among different levels of reality. Furthermore, there was a small community of Uighuri mathematicians in the Forbidden City since the age of the Mongolian domination. They had imported Arabic astronomy from Persia, having a sort of monopoly on astrological responses. It was not easy to compete with their undisputed authority.

Unfortunately for the Jesuit astronomers, the political situation changed dramatically in 1661, after Shunzhi's sudden death. His son Kangxi (1654-1722) was only 7 and the government was placed in the hands of four regents. Unlike Shunzhi, the regents were hostile to the Jesuits, as most of the Han, Manchu, and Uighuri mathematicians who worked at the Observatory and felt deprived of their previous prominent position as court astronomers, with the great influence that such a role had on the Emperor. This turned quickly into an open persecution campaign against the Jesuit missions and the minority of Christian Chinese. What followed was a complicated and novel-like affaire, much more than a court conspiracy against the Jesuits and their supporters: it was a sort of "Kulturkampf" raised by the most conservative side of the Manchu regime, which regarded the Europeans and their increasing authority as a threat for the stability and the cultural identity of the Empire.

In 1659 the Chinese astronomer Yang Guangxian (1597-1669), a former assistant guard commander during the late Ming period, wrote two anti-Jesuit pamphlets: *On Collecting Errors*, a criticism of the Western calendar, and *On Exposing Heterodoxy*, a violent attack on Christianity. In 1660 he sent to the Imperial Board of Rites *A Call to Rectify the Country*, which contained his first direct attack on Adam Schall von Bell, claiming that he wanted to westernize the Chinese calendar to introduce Christian liturgy. It was rejected. More writings followed over the next few years. These were collected in 1665 under the title *I Cannot Do Otherwise*. The most important of these articles appeared in September 1664: *A Complaint Requesting Punishment for the Evil Religion*. This time it was accepted by the Board of Rites. In it, Yang claimed that von Bell was responsible for the death of the young Empress Xian Rui in 1660 by choosing an inauspicious day for the burial of her son in 1658. Since Shunzhi had become depressed and ill because of Xian Rui's fate, von Bell was also responsible for the Emperor's death. The allegation was extremely serious.

Yang challenged von Bell to a public competition to decide which astronomy was the best one and he won, also because the majority of the court astronomers supported him against the Jesuit. Yang took von Bell's place as Head of the Mathematical Board. Having lost the competition, von Bell and the other Jesuits were chained and thrown into a filthy prison, accused of teaching a false religion. They were bound to wooden pegs in such a way that they could neither stand nor sit and remained there for almost two months until a sentence of strangulation was imposed. A high court found the sentence too light and ordered them to be cut up into bits while still alive. Fortunately for them, on April 16, 1665, an earthquake destroyed the part of the prison chosen for the execution. An extraordinary meteor was seen in the sky, and a fire destroyed the part of the Imperial Palace where the condemnation was pronounced. This was seen as an omen and all the prisoners were released. Only five Christian Chinese were executed. However, the Jesuits still had to stand trial, and all of them but von Bell, Verbiest, and two others were exiled to Canton. Von Bell died within a year, due to the very hard conditions of his confinement. The whole "enculturation" strategy was at stake at that moment, together with the survival of the Jesuit missions in China.

In 1669, the Kangxi Emperor managed to take power by having the remaining and corrupt regent arrested. In the same year, the Emperor was informed that serious errors had been found in the calendar for 1670, which had been drawn up by Yang Guangxian. Kangxi commanded a public test to compare the merits of European and Chinese astronomy. The test was to predict three things: the length of the shadow thrown by a gnomon of a given height at noon of a certain day; the absolute and relative positions of the sun and the planets on a given date; the exact time of an anticipated lunar eclipse. Yang and Verbiest should each use their mathematical skills to determine the answers: "the heavens would be the judge".

Behind the scenes of a public competition among courtesan scholars to compare the merits of European and Chinese astronomy, a dangerous game was played within the Forbidden City, which involved knowledge, instruments, philosophical issues, patronage, personal rivalry, and luck. The contest was held at the Bureau of Astronomy in the presence of senior-ranking government ministers and officials from the Observatory. Unlike Yang, Verbiest was assisted by telescopes for observations and had access to the latest updates on Kepler's *Tabulae Rudolphinae* (1627). He succeeded in all three tests, and was immediately installed as Head of the Mathematical Board and Director of the Observatory. Yang was sentenced to the same death he had planned for his Jesuit rivals, but he was pardoned by Kangxi and exiled to his native village, due to his old age. In 1671 the exiled Jesuits were rehabilitated and authorized to return to their missions.

The 1670 calendar unnecessarily included an extra intercalary month, added to hide other errors and to bring the lunar months in line with the solar year. Verbiest suggested that the errors should be corrected removing the extra month. This was an audacious move, as the calendar had been approved by the Emperor himself. Fearing Kangxi's response, the Observatory officials begged Verbiest to withdraw his request, but he replied: «It is not within my power to make the heavens agree with your calendar. The extra month must be taken out». Much to their surprise, the Emperor finally agreed, and it was done. After this, Verbiest became a close friend of Kangxi, teaching him geometry, philosophy, and music. He was frequently invited to the Imperial Palace and to follow the Emperor in his expeditions through the country. In 1673 Verbiest was elevated to the highest grade of the mandarinate, an extraordinary privilege that no other European would enjoy after him.

Having solved the issues surrounding the calendar, Verbiest went on to compose a table of all solar and lunar eclipses for the next 2,000 years. Delighted with this, the Emperor awarded him complete charge of the Imperial Observatory, which he rebuilt in 1673 according to modern standards. The current Observatory had been completed in 1442 under the Ming dynasty. The existing equipment was obsolete, dating back to the end of the 15th century, so Verbiest consigned it to a museum close to the main building and designed six new bronze instruments, which can still be seen nowadays. They are large and highly decorated, with dragons forming the supports. Despite their weight, they are very easy to manipulate, demonstrating Verbiest's aptitude for mechanical design:

- **Altazimuth**, to measure the position of celestial bodies relative to the horizon and the zenith – the altitude azimuth.
- **Quadrant**, six feet in radius, to measure altitudes or zenith distances of celestial bodies.
- **Equatorial armilla**, six feet in diameter, to measure true solar time as well as right ascension difference and declination of celestial bodies.
- **Ecliptic armilla**, six feet in diameter, to measure the ecliptic longitude difference and latitudes of celestial bodies. This was the traditional European device, while the Chinese used only equatorial armillas.
- **Sextant**, eight feet in radius, to measure the angle of elevation of a celestial object above the horizon and to calculate the angle between two objects.
- **Celestial globe**, six feet in diameter, to map and identify celestial objects.

Verbiest undertook also many other projects, including the translation of the first six books of Euclid's *Elements* into Manchu (a full Chinese translation of Euclid had been provided in 1607 by Matteo Ricci). He created star charts for the

Emperor in order to tell the time at night. In 1674 he published his Kunyu Quantu world map, an improvement of the *Kunyu Wanguo Quantu* map drawn by Ricci between 1602 and 1604. In 1687 he completed his *Astronomia Europea*, a Latin encyclopaedic treatise on the major achievements of Western astronomy, which was of course cosmologically committed with the Tychonian system. After his death in Beijing he was succeeded as chief mathematician and court astronomer by a Belgian Jesuit, Antoine Thomas (1644-1709). His remains were buried near those of Matteo Ricci and Adam Schall von Bell on March 11, 1688. Today their grave is in the campus of the University College of Political Science. Verbiest was the only Westerner in Chinese history to ever receive the supreme honour of a posthumous name by the Emperor.

His personal success in the "calendar affaire", as well as his unsurpassed intellectual and social prestige at the court of Kangxi, was for sure a breakthrough in the history of the Jesuit missions in China, if not its prime. However, it did not imply a success of the Jesuit programme of evangelization through "enculturation". On the contrary, the temporary defeat of the traditionalists was rather a victory of the Emperor, a landmark in his politics of cooptation of the most prominent members of the Company by placing them at key positions in the establishment, also to prevent any external aggression from the Europeans in reaction to a systematic persecution against Christians.

The real political contest was inside the new dominant class of the Empire. The Manchu leaders were traditionally strong supporters of Buddhist monasteries, since their respected authority was compatible with their respectful loyalty to the Emperor. Kangxi's assimilating attitude towards the Jesuits aimed at reducing them to one of the many ethnic-religious minorities protected by the imperial government because of their unquestioned obedience to it. This would become much clearer under the reign of his successors Yongzheng (1678-1735) and Qianlong (1711-1799): the dispute about the syncretic rites and the heterodox doctrines elaborated by the Jesuits would bring their missions to an end in the 1760s, putting the remaining former missionaries and the Christian Chinese under the total control of the Emperor.

Moreover, one might say that the dignitaries of the Celestial Empire had a very similar, pragmatic approach to the scientific and technological novelties introduced by the Jesuits, despite their undutiful importance. They regarded the "new astronomy", as all the other innovations imported by the Europeans, as useful upgrades and developments of their own traditional knowledge, without any significant change in their cultural background and in their "Weltanschauung", based on millennia of sophisticated civilization. The physic-mathematical sciences and their applications were the only field where a serious dialogue between the two sides could be established. Any worry about theological "orthodoxy", the initial need of removing any reference to the Copernican debate, all the attempts to reconcile Galilean mechanics with Tychonic astronomy and Aristotelian natural philosophy were actually a matter of discussion within the Company, but of no relevance at all for Chinese scholars, who regarded Western metaphysics and theology as very naive and self-contradictory, compared with the advancement of European science.

They soon recognized the many inconsistencies of the Jesuit conciliatory attitude, coming independently to the conclusion that their astronomy and mechanics were incompatible with Scholastic philosophy. Verbiest had the occasion to experience their sharp insight when in 1683 he dedicated to Kangxi a compendium of the main achievements of both Galilean and Cartesian physics, trying to present them as a whole. Despite his high reputation at court, he was harshly criticized by many mandarins, who had never recognized his exceptional and maybe undeserved status. They attacked Verbiest precisely on the impossibility to maintain Aristotle's distinction between "natural" and "violent" motion (which was in principle coherent with Confucianism), if one must agree with Galileo's results about free fall and projectile motion. Verbiest's book was basically a manual of experimental physics, with very few references to Aristotle. Anyway the Emperor accepted the dedication, given his personal friendship with Verbiest and the many useful notions contained in the book, certainly not for its theoretical relevance.

As a matter of fact, the Jesuits were on their turn object of a much more successful strategy of "enculturation". On the one hand, the Chinese scholars had no problems to replace a traditional but less developed astronomy with a foreign but more advanced mathematical physics, even when in 1760 the French father Michel Benoist (1715-1774) finally adopted Copernicus, Kepler, and Newton as basic sources for teaching. According to them, this simply meant to add new perfection to which was already perfect, with further advantages for the sciences and the arts. Why do not use more powerful, efficient, and fruitful means, if they were available? On the other hand, the Europeans had much to learn from the Chinese in almost all the other fields of knowledge. The question of the real constitution of the Universe was subordinated to the preservation of a cosmic harmony which should reflect and be reflected by the mundane order. The idea that nature must obey to necessary and immutable laws fitted very well into the Confucian framework. The fundamental unity of metaphysics, natural philosophy, ethics, and politics had just to be reconsidered on much better (but not totally new) cosmological bases.

NATURAL HISTORY AND MEDICINE FROM THE 16TH TO THE 19TH CENTURY

Abstract

Due to the rich content of Girolamo Mercuriale's De arte gymnastica *(Venice, 1569), drawing from other than purely medical sources (textual as well as material), the task of designating the medical nature of the book in its full spectrum suggests at the same time the mapping of the boundaries of sixteenth century medicine as well as the book's "scientificity", as the product of a sixteenth century "rational and learned" physician. Mercuriale's diagnosis of "new diseases" and his prognosis of "future" diseases surprisingly (or not) direct the "modern" readers (medical men and others) of the book back to antiquity to find the proper method of medical treatment for all the "modern" scourges. In this framework, aspects of the ancient past are reconstructed in "medical" images and they are examined through textual and material (antiquarian objects, remaining, etc.) sources which are interpreted in "modern" terms so as to demonstrate the timeless medical value of the ancient, "traditional", "indigenous" culture. In the* De arte gymnastica *aspects of the ancient Greek and Roman culture are being medicalized by Mercuriale with the aim to form a "modern" medical art: the "art of gymnastics". In this medical discourse on health, disease and treatment Mercuriale raises issues regarding the limits and the credibility of the contemporary corpus of medical knowledge, its format and content, the focus of contemporary medical practice, as well as the nature and the effects of practices of contemporary lifestyle, having two "scientific" criteria: the notion of a healthy human body acknowledged as the actor of everyday life and culture, and the opinion that medicine can be benefited from other fields of knowledge too. How is the scientific nature of this medical book to be designated and which is its content?*

The present paper examines the use of architectural design in the making and the communication of the medical discourse impressed in the *De arte gymnastica*,[1] the work of the renowned medical humanist Girolamo Mercuriale (1530-1606). This medical book was first published in Venice by the Giunta Press in 1569, and its first edition featured a single illustration: the ground-plan of an ancient *gymnasium* (or *palaestra*). The second edition of the book, published by the same publishing house in 1573, was enriched with many more illustrations, courtesy in their majority of the painter, architect and antiquarian Pirro Ligorio (1513-1583). Among the illustrations of the second edition we find two such ground plans: one of a square and one of an oblong palaestra.

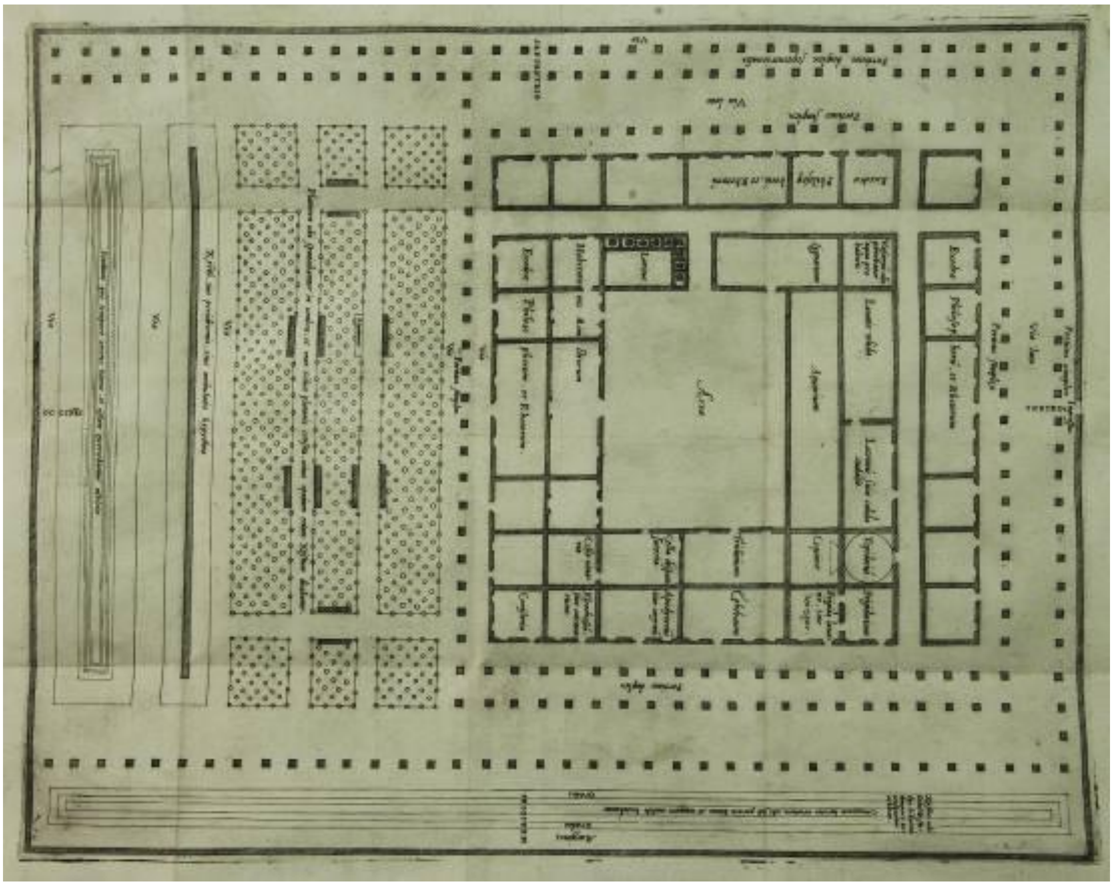

Fig. 1: The illustration of the ground plan of the ancient *gymnasium* (*palaestra*)
in Girolamo Mercuriale's *De arte gymnastica* (Venice, 1569).
Courtesy of the Biblioteca Nazionale Centrale di Roma.

The pictorial material of Mercuriale's *De arte gymnastica* has attracted much scholarly interest;[2] however scholars have focused mainly on the enriched, second edition of the book. In this way, much less has been said about the presence of this single illustration of the first edition of the *De arte gymnastica*, which is surprising especially when considering the elaboration of the particular drawing in the second edition of the book. More importantly, the use of such a *type* of drawing in an early modern medical book has not yet been problematized. In this paper I would like to offer some considerations

regarding how in the context of the *De arte gymnastica* the use of an architectural design –viewed as an aspect of the circulation of architectural as well as antiquarian knowledge, interests, methods and practices, as this took place in mid-sixteenth century Rome– played a role in the making of Mercuriale's medical discourse as well as its communication to his audience, identified primarily as the Roman social (religious and lay) elite.[3]

I would suggest that Mercuriale's deployment of an architectural design in his *De arte gymnastica* presupposed and implied as well, the circulation of a series of elements; the drawing of the ground plan of an ancient palaestra in Mercuriale's book appears as the meeting point of classical authoritative texts as recovered by humanists, antiquarian interests and practices, ideas and values, as well as architectural interests and methods, as their circulation took place within a local context, that of mid-sixteenth century Rome. What I argue in this paper, is that in the context of the *De arte gymnastica* the deployment of this architectural design makes part of Mercuriale's endeavour to (re)construct and effectively communicate practical information as well as values and principles (ethical and cultural) in relation to what he defines as 'medical gymnastics', which he promotes in his book as a method of medical practice and treatment –and a legitimate part of *medicina conservativa* (or *hygiene*)– for the "new" as well as the "future diseases".[4]

Mercuriale wrote his *De arte gymnastica* during his staying in Rome, in the years 1562-1569, where he served as a practicing physician in the household of Cardinal Alessandro Farnese (1520-1589), to whom the first edition of the book was dedicated. It is in the 'Roman context' therefore, that the present paper suggests that the use of the architectural design in Mercuriale's book should be viewed.[5] There, as a member of the Cardinal's court being situated in the heart of the papal court, being a large however one amongst the numerous Roman courts (curial and lay), and, as such, making part of the broader social and cultural space of the city, Mercuriale had the opportunity to live and work among members of the local intellectual *milieu* with common interests, values and principles, as well as a common 'noble' lifestyle. Two areas where all these found a vivid expression during the sixteenth century, were the fields of antiquarianism and architecture.

Cardinal Alessandro Farnese himself, one of the greatest patrons of art and architecture at the time, had a known interest in the Greco-Roman classical culture while he owned a notable collection of antiquities.[6] Of course, by no means he was the only patron with such interests and pursuits in Rome at the time. Building and architectural (mainly secular) projects sponsored by noble individuals or families, was an area were humanist ideas and ideals as nurtured in the Roman court-life, were manifested pursuing a classical urban style and decorum for what was built and planned in Rome at the time, public and/or private.[7] These projects were greatly pre-informed on one hand by antiquarian research in the effort to achieve successfully the reconstruction, restoration of the classical Rome within the modern Rome, and on the other hand by architectural values and ideas inspired and/or drawing from (to a greater or to a lesser extend) the classical authority of Vitruvius and his work *De architectura libri decem*.

Vitruvius' *De architectura*, the only full treatise on architecture and its related arts that had survived from classical antiquity, was one of the most influential and disseminated classical texts that had a significant impact on renaissance thought.[8] After the discovery of its existence in the early fifteenth century, it was recovered by important humanist figures and was published in printed form (as well as in illustrated and translated, from Latin, editions) numerous times during the fifteenth and the sixteenth centuries.[9] It became widely diffused as a point of reference among the dedicated enthusiasts having a general or more specialized interest in antiquity and ancient architecture: those interested in the Roman ruins, those interested in designing buildings *all'antica*, those who were interested in the reconstruction and/or restoration of the ancient

[8] See Ingrid D. Rowland and Thomas Noble Howe, *Vitruvius. Ten Books on Architecture*, (Cambridge: Cambridge University Press, 1999); Ingrid D. Rowland, *The culture of the High Renaissance: ancients and moderns in sixteenth-century Rome*, (Cambridge: Cambridge University Press, 2000).

[9] Among the most important editions we find the ones by: Fra Giovanni Giocondo (an illustrated edition printed in 1511 in Venice, reprinted in 1522 in a revised edition in Florence), Cesare Cesariano (the first edition to be published translated in Italian, in 1521), Daniele Barbaro (in 1556, with illustrations by Andrea Palladio).

Roman buildings, etc., found an important tool in Vitruvius.[10] Among those enthusiasts we find Mercuriale too, who in his endeavour to provide an accurate description of the ancient Roman palaestra, turns to his erudite Roman acquaintances familiar with the work of Vitruvius as well as the city of Rome, so as to be provided with a reliable interpretation of the respective part of the *De architectura*, namely the *De palaestrarum aedificatione et xystis* ('The construction of the *palaestra* and its porticoes') from Book V, Chapter XI of Vitruvius' treatise.

In the first edition of the *De arte gymnastica*, Mercuriale notes that the description of the palaestra is based on the interpretation of the respective part of Vitruvius' work offered by Ottavio Pantagatho,[11] who was an antiquarian and one of Mercuriale's acquaintances in Rome. The drawing corresponds to the textual description provided, as it visualizes the different parts of the palaestra, which are recited in full writing on the drawing itself. Judging from the importance that Mercuriale attributed to a correct interpretation of Vitruvius as well as from the correspondence between the drawing and the textual description provided, the accuracy of the drawing rested exactly on the accuracy of the interpretation of the Vitruvian text.[12]

In fact, Mercuriale in the second edition of his book notes how he provides the reader with a meliorated interpretation of Vitruvius, benefited this time from the help of Alvise Mocenigo (son of Francesco), Gian Vicenzo Pinelli, Melchior Guilandino and Andrea Palladio, identifying the latter as the greatest expert in the field of ancient architecture.[13] In these terms, he notes how he also provides two such ground plans, because the author (Vitruvius), Mercuriale marks, says that the palaestra could be both square and oblong.[14] Given the framework and the length of this paper, I am not going to examine either the elaborated textual description, or the addition of the second ground plan, or the different placing of the illustrations in the second edition of the book;[15] rather I would like to offer a series of suggestions regarding primarily the *use* of such a *type* of drawing in the context of Mercuriale's medical discourse. In order to do this I will focus on the *synergy* between text and image and map its effect in relation to the primary audience of Mercuriale's book: the Roman social elite.

In the first edition of the *De arte gymnastica* we find the ground plan of the palaestra placed in the first, opening pages of the book, exactly before the opening of Book I. Nonetheless, as noted earlier, the drawing follows a textual description of the Vitruvian palaestra, which Mercuriale provides in Book I of the *De arte gymnastica*, Chapter VI, entitled *De gymnasiis antiquorum* ('The gymnasia of Antiquity'). On the drawing we find impressed the different parts of the palaestra recited in full writing and as indicated in the textual description provided in the chapter. In these terms, the illustration corresponds to and makes part of the particular chapter, as it is associated to the text and it visualizes, conveys information found in the text. But what is the chapter about?

The chapter begins with Mercuriale noting *that* "*after establishing that gymnastics or the art of exercise used to be practiced in specific places, it is reasonable to explain what the places themselves where and of what sort*".[16] Indeed, Mercuriale begins with asserting that gymnastics in the ancient times was practiced in specific places called gymnasia and giving the definition of the word *gymnasium* (from the Greek word *gymnazesthai*, i.e. to become naked) he tackles the scandalous issue of nakedness by noting that it was not certain that all who exercised only for the sake of health took off their clothes. Following, Mercuriale gives a brief history of the first Greek and Roman gymnasia, in which he brings up a series of explanatory and clarifying points regarding the names employed to describe gymnasia in the Roman times, as well as regarding the use of the gymnasia. In this framework, Mercuriale notes how Latin-speaking authors used other terms that described or designated the Greek gymnasium and he also makes a distinction between the original gymnasium and places introduced for other purposes and activities (e.g. for education, or other arts and festivals).

What is worth noting is how Mercuriale emphasizes on particular parts of the ancient gymnasium and aspects of its use. He notes characteristically how Plato and Aristotle were in the habit of doing philosophy in the (so-called) Athenian gymnasia: the Academy and the Lyceum respectively. As regards, he also marks how the Academy was considered "*the*

[12] In fact, the original Vitruvian text was difficult to comprehend fully as it was not illustrated and it made use of technical terms in Latin and in a mixture of Greek and Latin. See *Andrea Paladio. The Four Books on Archittecture*, transl. by Robert Tavernonr and Richard Schofield, (Massachusetts: MIT Press, 1997), p. vii.

[13] '[…] *Andreas Palladius priscae totius architecturae peritissimus*' in Girolamo Mercuriale, *De arte gymnastica*, (Venice, 1573), Liber I, Caput VI, De Gymnasiis Antiquorum ('The Gymnasia of Antiquity').

[14] See Girolamo Mercuriale, *De arte gymnastica*, (Venice, 1573), Liber I, Caput VI, De Gymnasiis Antiquorum (The Gymnasia of Antiquity').

[15] These are issues that I have identified as 'problems' and I examine analytically in my PhD thesis.

[16] 'Gymnasticam, sive exercitatoriam, in certis locis fieri solitam, quoniam supra statuimus, rationi modo consentaeum, est quid loca ipsa et qualia forent planum facere', in Girolamo Mercuriale, *De arte gymnastica*, (Venice, 1569), Liber I, Caput VI, De Gymnasiis Antiquorum ('The Gymnasia of Antiquity').

noblest gymnasium on earth".[17] Calling on the authority of Vitruvius, Mercuriale marks how the gymnasia were by structure appropriate to host exercises of *both* the body and the mind, as they had a large capacity and they were great in extent. He notes characteristically that in the gymnasium "*it was possible to carry out without any hindrance numerous exercises of diverse types, of both body and mind*".[18] The chapter ends with the analytic description of the structure of the gymnasium and the use of its parts.

Judging by the content of the chapter I would suggest that Mercuriale is mostly concerned to define the palaestra as a physical space and regarding its use; initially asserting what the gymnasium was and what it was not, and in the following regarding its function (exercise of both the body *and* the mind) explaining how this was in fact served by the structure of the gymnasium. In this framework of description-definition of the palaestra, Mercuriale tries to demonstrate that the gymnasium was a perfectly legitimate and decent public place, where people (among them learned men of high authority such as Plato and Aristotle) could practice both bodily and intellectual activities. As such, in Mercuriale's discourse the ancient palaestra appears by structure to be the appropriate place for the exercise of the body (and of the mind), qualifying as well as to the status of the noble people who attended it or whish to attend it.

In these terms, I would suggest that Mercuriale's aim in this chapter is to provide an *image* of the palaestra, such, that it would correspond to the art of gymnastics promoted in his *De arte gymnastica* as the *noble* art of exercise for medical reasons (i.e. the 'medical gymnastics'),[19] suitable to the decorum of his noble audience. To put it in other words, through this discourse Mercuriale tries to dis-implicate the ancient palaestra (as the place were gymnastics was practiced) from its notorious fame owing to activities taking place there that were stigmatized as 'immoral' and 'irregular' with the decline of the Roman world, as well as in Mercuriale's time especially in the framework of post-Tridentine attitudes. In this way, he dis-implicates medical gymnastics as well, so as to promote it as a noble and gentle method of medical practice appropriated to the status and the decorum of his audience. This dis-implication could have worked in two ways in the framework of Mercuriale's professional agenda: it could either legitimize 'ambiguous' bodily activities practiced by members of the elite by attributing to them a medical value,[20] and/or promote the decorum of this medical treatment to members of the elite who were primarily interested in intellectual activities and thought less of bodily activities.

But how does the ground plan of the palaestra make part of this discourse on the noble qualities of the gymnasium and –subsequently– of Mercuriale's medical gymnastics? To answer this question it would be useful first to look into the illustration itself. The drawing is an orthographic projection, which, as a formula, constituted a chief graphic device for the sixteenth century architects.[21] It was a method to represent the interior and exterior elevations of a building, not in perspective but laid out flat in a consistent scale. In this way, every measurement and relationship of each part of the building to each other and to the whole of the building may appear on the drawing as on the building itself, only reduced by a consistent factor. As a drawing it was more abstract, but it could be translated directly from the drawing into the actual building and vice versa.[22]

This is something that had not been possible with earlier perspective drawings in which measurements were affected by the position and distance of the observer. James Ackerman has suggested that, as such, the orthographic projection was an expression of the Renaissance architects' concerns regarding the rationalization of proportion and the refinement of techniques of representation, in their endeavour (as dictated by the humanist ambitions) to describe accurately and systematically the ancient physical remains. In these terms, Ackerman suggests that this type of drawing was not merely a means to record the visible ancient findings and physical remains; rather it was a 'tool' to design a *model* of a building for others to follow.[23]

In this context, the deployment of Vitruvius is of crucial significance. Vitruvius' concern to provide architecture with a distinct structure and order, as well as his view that geometry, measure and proportion were the qualities and characteristics of the Greek and Roman architectural achievements, were considered unsurpassed paragons for Renaissance architecture;

---

[17] '[…] in academia Atheniensium nobilissimo totius orbis gymnasio' in Girolamo Mercuriale, *De arte gymnastica*, (Venice, 1569), Liber I, Caput VI, De Gymnasiis Antiquorum ('The Gymnasia of Antiquity').

[18] '[…] innumerae exercitationes et corporum et animorum peragi possent…ex Vitruvii allata descriptione' in Girolamo Mercuriale, *De arte gymnastica* (Venice, 1569), Book I, Chapter VI, De gymnasiis antiquorum ('The Gymnasia of Antiquity').

[19] In contrast to the military and athletic gymnastics, the medical gymnastics were considered the only legitimate type according to Galen.

[20] Practices of the court-life mentioned by Farnese's delegates, such as wrestling, dance and hunting (see Clare Robertson, *op. cit*., pp. 75-76) are listed as 'exercises' with a medical value by Mercuriale in his *De arte gymnastica*.

[21] See James Ackerman, 'The Involvement of Artists in Renaissance Science" in John W. Shirley and F. David Hoeniger (eds.), *Science and the Arts in the Renaissance*, (London and Toronto: Associated University Press, 1985), pp. 122-124.

[22] *Ibid*.

[23] *Ibid*.

they mirrored the beauty of nature and of the human body.[24] In these terms, the sixteenth century experts and enthusiasts found in Vitruvius the means with which they could interpret the remains of ancient buildings, measuring them and then restoring their forms in drawing. In this way they could design buildings *all'antica* reviving the harmony that the ancients sought between nature, the human body and architecture.[25] With the deployment in the context of the *De arte gymnastica* of the ground plan of the palaestra following Vitruvius and the aforementioned values that his work entailed, I would suggest that Mercuriale aims to provide such a model, expressing the Renaissance attitude according to which the classical antiquity should primarily serve as a model and standard for contemporary life.

Nonetheless, the ground plan of the palaestra serves functional purposes too. The deployment of the orthographic projection enhances Mercuriale's effort to describe analytically and systematically the ancient gymnasium as a physical space, and to recite and define its parts and their use, in a way that parallels the respective interest of anatomists and anatomical illustration. It is a type of visual depiction that demonstrates Mercuriale's taxonomic concerns as well as his endeavour to define and regularize (in practical as well as in ethical terms) the place and the uses of the gymnasium in relation to what he identifies and promotes as 'medical gymnastics' in his *De arte gymnastica*.

The orthographic projection, inspired from the fields of architecture and antiquarianism as manifested in Rome at the time, and in the context of Mercuriale's *De arte gymnastica* sustains a 'visual language' of communication between Mercuriale and his audience. It is a kind of encoding, enhanced with an epistemic value owing exactly to the ability of the audience to make the necessary inferences. If the audience was unfamiliar with the conventions deployed, then the utility of the illustration was to be compromised.[26] However, Mercuriale was addressing to an audience familiar as much with Vitruvius' work and the values and principles entailed in it, as with the use of this particular type of architectural design and its conventions. Cardinal Alessandro Farnese himself had a great fascination with architectural projects and he was very much conversant with architectural technicalities.[27]

In these terms, I would argue that the synergy between the text and the architectural design suggests Mercuriale's endeavour to offer a *model* of the ancient palaestra in its practical as well as its ethical qualities according to the Vitruvian values and principles, shared by Mercuriale's audience in early modern Rome. Mercuriale deploys this model in his medical discourse, promoting his medical gymnastics as a decorous –therefore appealing to the elite– method of medical practice and treatment, aiming to correspond to the contemporary medical, but as well as cultural and other needs, challenges, aspirations or trends as manifested by the Roman elite at the time. Surrounded in Rome by members of the religious and lay nobility who were interested in the ancient Roman and Greek past and bodily culture, interested in antiquarianism and in architecture, familiar with Vitruvius, as well as involved in building and architectural projects, Mercuriale, a University educated practicing physician, draws from the think-tank of this milieu in the making of his medical discourse. At the same time, with the same resources of thinking and conversing he addresses this milieu back promoting his professional agenda. In Mercuriale's *De arte gymnastica* we can see how a set of 'non-medical' elements (texts, practices, methods, ideas, etc.), as these were circulated and manifested within a particular local context, were deployed as resources in the making of a medical discourse, articulating and communicating practical as well as ethical aspects and qualities of the suggested medical treatment to an initiated audience.

Abstract

This study covers a remarkable period of European history –The Renaissance– and its main objective is to study the contribution of the Portuguese doctor Amato Lusitano (1511-1568) to the development of European Medicine in the sixteenth century.
In terms of methodology we used the content analysis, using data collection to the Portuguese edition of Seven Centuries of Medicinal Cures*, published by the Faculty of Medical Sciences, New University of Lisbon, in 1980.*

Amato Lusitano is one of the major references of European Medicine of his time. It was worth the frontispiece portrait of books from colleagues (as, for example in *Portada de História Plantarum* of João Bauhino). Its services were ordered by characters as diverse and distinct as the Pope, the King of Poland, the city-state of Ragusa, or the Grand Vizier of the Ottoman Empire (Correia *et al.*, 1968; Dias, 1936).

Amato Lusitano was born in Castelo Branco, with the given name of João Rodrigues, he was only 14 when he went to Salamanca to study medicine. It is possible to deduce that he was a brilliant and hard-working student, for, when he was only eighteen, their teachers didn't hesitate to give him the management of wards with several patients. From his stay in Salamanca, he left us some references to teachers and fellow colleagues. It is possible that some of its teachers were António de Nebrija[1], Fernando Nunes, also called the Pinciano, Pontano and Olivares[2], and the one who Amato more recalls

[1] V *Centúria*, Cura C, p. 293.

[2] VI *Centúria*, Cura C, p. 163.

in one of his works, Lourenço Alderete. As for his colleagues, he mentions, among others, the names of Luís Nunes, João Aguilera, and André Laguna.

After graduation he returned to Portugal to, shortly afterwards, start a long pilgrimage to Northern and Southern Europe. His dedication to Medicine, but above all the desire for new knowledge, led him to long journeys in Portugal and several European countries. Amato mastered perfectly eight languages including Spanish, Portuguese, Latin, Greek, Arabic, and Hebrew. Building on this, he could well and freely transfer himself to any cities or countries where he found favorable conditions for the exercise of the medical profession (Jorge, 1914).

In 1533 he left for Antwerp, where he remained for about seven years. At this stage he began creating a reputation that transcended borders, and his medical services were repeatedly asked for in other countries and cities. While practicing medicine, he also worked in scientific research. In 1536, in Antwerp, he publishes his first work, the *Index Dioscorides*. This is the only work where Amato uses his given name, João Rodrigues de Castelo Branco, as it is possible to see on the cover of the existing copy in the Library of Évora (Correia *et al*., 1968; Dias, 1936).

Of the many people he was related to in Antwerp, it is possible to mention the humanists Erasmus (1584-1653), Conrado Goclenio, and Luiz Vives, tutor of Princess Mary of England.

In 1541, he left Antwerp and headed for the ducal court of Ferrara, probably attracted by promises of Hercules II d'Este, which allowed for the practice of Jewish religion. In this town, one of the brightest in all over Italy in sciences, letters, and arts, Amato amounted to the biggest celebrity that a doctor could aspire: the rank of professor. It is possible that, at Ferrara, Amato was the court physician, since he refers to a disease that Diana d'Este, a relative of Hércules II, was suffering from. He also mentions some contacts with famous doctors who had worked in the same town, including Savoranola, Hugo de Sena, Leoniceno (1428-1524), and Nicolas Monardes (1493-1588). It was during this period that Amato studied the properties of simple, counting for this purpose on the cooperation of the influential anatomist Gabriel Fallopio (1523-1562), who taught medical botany at Ferrara (Rodrigues, 2005).

António Musa Brasavola (1500-1555) and Giambattista Canano (1515-1579) were two doctors from Ferrara with whom Amato had friendly relations. The first was a disciple of Leoniceno and Monardes (1493-1588), was physician to several distinct figures, such as Charles V, Henry VIII, and the Popes Paul III, Leon X, and Clement VII. As for Canano, Amato considers him an expert anatomist, comparable to Vesalius. It was in the presence of this colleague, together with an assembly of other doctors, that Amato made the dissection of 12 human and animal bodies, where he encountered, at the opening of the azygos vein in the vena cava, valves that prevented the backward travel of blood (Rodrigues, 2005).

Meanwhile, Amato was invited to practice medicine in Ragusa but this was slow to materialize. Amato goes to Ancona, by then an important commercial town, whose development seems to have been closely associated with the Jewish community. At Ancona, Amato continues his professional practice and the preparation of Works for publication, concluding the first of the *Centúrias Medicinais*, *Curationem Medicinalium centuriae septem*, on December 1st, 1549.

Shortly after being established in Ancona, Amato went to Venice where he resided for a short period. In this town, he contacted doctors that he considered particularly skilled, namely Baptista Montano and Victor Trincavelle. It is known that both of them were professors at the University of Padua and that they left some works of reference (Correia *et al*., 1968; Dias, 1936).

In 1550, Amato is asked to go to Rome to look after Pope Julius III. Although the ills that afflicted the Pope are, as a rule, described as pleurisy, pneumonia, or other respiratory problems, evidence recorded in the *Centúrias* indicates that the Pope was rather suffering from syphilis, since Amato treated him with the root of China, a plant used in the treatment of this disease (Jorge, 1914).

Amato lived in Rome until the end 1551. Then, he went to Florence where he met Cosimo de Medici.

In 1552, perhaps due to a security issue, he went back to Ancona, then part of the papal territory. After the death of Pope Julius III (1555), whose pontificate was marked by a favorable treatment to the Jewish community, the new appointment fell on Paul IV. Numerous decrees were immediately promulgated against the Jews and, once more, their lands and fields were expropriated. Jewish doctors were forbidden to treat Christians, "ghettos" were settled and many Jews suffered imprisonment and torture (Lemos, 1889). When he received the announcement of the arrival of the emissaries of the new Pope, Amato left immediately for Pesaro. On withdrawal, he lost all his possessions and the considerable personal library, which he greatly regretted, as well as two important manuscripts, the *V Centúria* and some *Comentários sobre O livro de Avicena* [Comments on The book of Avicenna].

Amato remained only a few months in Pesaro, since, in August 1556, he finally went to his post in Ragusa. During the time he was in Ragusa, Amato pursued private practice, which enabled him to write several clinical cases that are depicted in the VI *Centúria*. We know that it was during his stay in Ragusa that Amato had a misunderstanding with serious consequences with Pietro Mattioli.

In May 1559, Amato finally gives up to find peace and security in Ragusa, then heading out to Thessaloniki. There, he actively exercises the clinic until his death from plague, on January 21, 1568.

Of the three works he left us: *Índex Dioscódires*, *Ennarraions* and *Curationum Medicinalium centuriae septem, varae multiplicique rerum cognitione referte; quibus praemissa est commentatio de introitu medici ad agrotantem, deque crisi et diebus decretoriis*, Burgos, 1620 –Seven Centuries of medical cures, the third one was the most publicized and that had more impact at the time.

The *Seven Centuries of medical cures*, the object of our analysis, is a collection of valuable observations of Surgery and Medicine, collected throughout his travels through Europe.

This work was first published in 1580 in Leon, when Amato had already died, and was reissued, complete or fragmentary, at least 57 times (Correia *et al*., 1968).

This number of reprints shows the influence that the *Centúrias* had, for several years, within several academic groups, namely doctors and Medical students from multiple universities in Europe. Each *centúria* includes 100 clinical cases (cures). It consists of two parts: in the first part, the presentation, patient's history, treatment, clinical; and then the Comments which evokes the classic and modern, discusses the effect of drugs, changes in treatments.

It is worth noticing that the comments and interpretations of Amato, although influenced by the philosophical and scientific mentality prevailing in Europe at the time, are remarkable. We can see from this table where references to Galen and Hippocrates dominate, which are usually the starting points for the presentation of clinical cases as well as to the type of therapy to be applied. He follows Avicenna, that Amato considers a "most learned man" and that, in his opinion, must be placed right after Galen. Amato often presents some contemporaries, such as Monardes, Andre Vesalius (1514-1564), Andre Laguna (1510-1562), or the anatomist Giambattista Canano. This means that Amato accompanied the works and discoveries of his colleagues (Rodrigues, 2005).

We found that the themes related to sexuality represent a significant proportion of the clinical cases. It is with this work that sexology is defined as a clinical matter, by the abundance of cases and the naturalness of their presentation –that occurs alongside other matters requiring the attention of the doctor– and by the uniformity of the clinical terminology used, completely identical to that used for other cases.

The *Centúrias* can be read as one of the first medical works where the rudiments of sexual disturbances begin to be drawn, that later on would become integrated into the science currently identified as clinical sexology (Rodrigues, 2005).

The approach to these matters has raised some controversy at the time. And the works as well as its author were subject to censorship. It is possible to find the presence of Amato Lusitano in the Index of forbidden books by the end of the 16th century. The name of Amato Lusitano appears, as a forbidden author, in the Indexes of 1581, 1612, 1632, 1640, and 1707. Amato is again the subject of censorship in the *Index auctorum damnatae memoriae*, published in Lisbon, in 1624. This Index contains several other authors, such as Alberto Magno, Arnaldo Villanova, Leonardo Fuchs, and André Laguna (Front, 2001; Tomás, 1991).

Conclusions

By the end of the 15th century, due to various social, economic, academic, and political factors, the whole European culture had undergone a profound transformation. This awakening of Europe to new values and ideas was characterized by what was conceived, at the time, as a renewal of the human spirit, leading to a new conception of life.

Amato Lusitano actively participated in this hectic time of European knowledge. Like all men living in critical times, in which traditions are questioned and generating new conceptions of humanity and the world are generated, he left us the legacy of a troubled soul, curious, eager to learn and improve. Although in his work dominates the spirit of inquiry and empirical observation, his angle of approach was necessarily affected by the contradictions of his time: on one hand, he had been formed within the framework of thought of ancient authorities, such as Galen and Hippocrates, or the scholastic tradition; but, on the other hand, he was attracted by the "new science", with its objective attitude, creative and free, focused on nature and man –adding that often his own observations led him to deny the Classic authors.

We consider, for all that we just said, that Amato Lusitano and his works were references in 16th century medicine.

WANDERING *EXOTICA*. THE ILLUSTRATIONS IN NIEREMBERG'S *HISTORIA NATURAE* (1635)

José Ramón MARCAIDA
CSIC – Consejo Superior de Investigaciones Científicas, SPAIN
joseramon.marcaida@cchs.csic.es

Abstract

Juan Eusebio Nieremberg's Historia Naturae *(1635) constitutes a rare contribution to natural history and natural philosophy coming from Spain during the first half of the seventeenth century. Featuring a theologically oriented approach to nature, mainly focused on the curious and the rare, the book is particularly noteworthy for the way it makes use of the materials (texts and illustrations) gathered by Francisco Hernández during his expedition to the New World in the 1570s. The story of these materials is well known among scholars, especially in relation to the Roman edition of Hernández's texts and illustrations produced by the* Accademia dei Lincei*. Nieremberg's treatment of these materials, however, has not received as much attention, despite some significant work being done on the American flora featured in his book. The purpose of this paper is to focus on the visual content of* Historia Naturae *and interpret it as a reflection of the kind of processes involved in the production and distribution of natural knowledge, in particular, circulating images representing unknown subjects such as New World animals and plants.*

The aim of this presentation is to examine a particular case of circulation of knowledge by visual means: the corpus of illustrations featured in the book *Historia naturae, maxime peregrinae* (Antwerp, 1635), by the Jesuit scholar Juan Eusebio Nieremberg (1595-1658).[1] Active in Madrid for most of his life, Nieremberg was a well-known figure in seventeenth-century Spain, mainly due to his numerous religious writings.[2] Interestingly for the history of science, Nieremberg was also the first holder of the chair of natural history at the Reales Estudios –inaugurated in 1629– of the Jesuit Colegio Imperial in Madrid. In

[1] This paper is based on materials discussed in my ongoing Ph.D. project devoted to Nieremberg and Baroque science in seventeenth-century Spain. I would like to thank the FPU Grant Program of the Spanish Ministry of Education and research projects HUM2007-63267 and HAR2010-15099 for their support, and the attendants at the ESHS meeting in Barcelona for their comments.

connection with these teaching duties, he produced several works devoted to natural philosophy and natural history, including *Historia naturae,* the most important and internationally oriented of them all.[3]

Nieremberg's aim in this book is twofold. On the one hand, it intends to present a description of New World *naturalia*, with a special emphasis on the rare and curious. This constitutes the content of Books VIII-XVI, which begin with human beings and end with minerals and the elements. But before that, in the first seven books, he provides a natural philosophical account of the New World in order to explain –this still remained an important question at the time– the origin of men, animals, plants, natural elements in general, there. How did they reach these lands? Did they exist before the Flood? As it is stated in the title of the book, the presence of unknown creatures in the New World posed the question of how this evidence agreed with the Biblical account of the Creation, which for Nieremberg provided the appropriate framework to understand the origins and constitution of the natural world. Above all, by looking at rare and curious phenomena, the ultimate aim of the book is to praise God's creation and God's masterly design.[4]

The book is a fine example of bookish accumulation. Nieremberg, who hardly left his studio in Madrid, quotes from many authors and many sources: books, manuscripts, reports, etc. In this regard, one of the most important aspects of this book is Nieremberg's use, for most of the treatise, of a particular set of materials: those gathered by the Spanish physician Francisco Hernández during his expedition to New Spain. The expedition was probably the most important project of sixteenth-century Hispanic science.[5] In 1569, Philip II nominated Francisco Hernández (1515-1587) his «chief medical officer of the Indies», and sent him on a mission to collect as much information as possible on the people, the fauna and the flora of New Spain and Peru. The expedition lasted from 1571 to 1577, and only New Spain was explored. Still, Hernández was able to provide descriptions of thousands of new plants, as well as hundreds of descriptions of animals, minerals and other phenomena. The materials he sent from Mexico amounted to a sixteen-book work of about nine hundred pages and around two thousand pages of illustrations. Hernández, however, did not edit these materials. In 1580, the Neapolitan physician Nardo Antonio Recchi was commissioned by Philip II to «put in order» the content of these admittedly messy volumes, in order to «make them useful». Recchi thus made a selection based on medical usefulness, and finished it by 1582. He took a copy of his selection with him, as well as a copy of around six hundred images, and returned to Naples. The idea was to publish his selection (text and images) in Spain but the project did not succeed. The original manuscripts and illustrations gathered by Hernández, who died in 1587, remained at the Library of the Real Monasterio de El Escorial until 1671, when a great fire destroyed them.

The story of these materials is certainly convoluted and fascinating, particularly in the way it runs parallel to the story of the Roman *Accademia dei Lincei*.[6] Highly devoted practitioners of any form of natural knowledge, the Linceans became very interested in the materials from the Hernández expedition, to the point that they bought Rechhi's selection from his heir, and made copies of his illustrations, with the aim of publishing a treatise on the natural history of the New World. The result would be the *Rerum Medicarum Novae Hispaniae Thesaurus* (Rome, 1651), also known as the *Tesoro Messicano*, the *Mexican Treasury*. The genesis of this book was long and complex. Its editing process, which began around 1610, under the direction of Federico Cesi, the founder of the Academy, did not finish until 1651, when Cesi and the majority of the Linceans had already died.

It is in this context, several years before the publication of the final version of the *Mexican Treasury*, that we have to consider Nieremberg's *Historia naturae*, a book which should be regarded as a rivalling work. Unlike the Linceans, which were using Recchi's selection as their main source, Nieremberg not only had had access to the original materials kept at the Escorial but had also been able to use Hernández's own manuscripts, which had been kept at the library of the Colegio Imperial since the doctor's death. The *Carteggio* –the compilation of Lincean correspondence edited by Giuseppe Gabrielli– contains only one reference to the Jesuit's work, in a letter by Johannes de Laet, director of the Dutch West India Company,

addressed to a friend of the Linceans in Rome.[7] The aim of the letter is to get updated information about the editing process of the Lincean book. In particular, Laet wants to confirm the news that such an important and long-awaited volume would not see the light due to the publication of a similar book –Nieremberg's *Historia naturae*. In fact, he seems surprised, for, in his view, this new work is not important enough to stop the publication of the Lincean treatise. Why? It is not about the text, he claims, but about the illustrations that would complement the descriptions of American *naturalia*: «[Nieremberg] has provided no images besides those which Clusius and others have already given». Novelty, originality. For a book about the natural history of the New World –Laet is saying– not only it was crucial to feature images; without novel ones, the book was not as worthy.

Against this backdrop of circulating materials, in the following pages the illustrations in *Historia naturae* will be described, with the double aim of examining to what extent is Laet's evaluation of Nieremberg's book accurate, and in which sense the value of Nieremberg's contribution to natural history could be measured in terms of its visual content.

Historia naturae features seventy images, all of them woodcuts. Twenty six are devoted to animals, eighteen to birds, seven to aquatic creatures, four to reptiles and fifteen to plants. None of them are devoted to human beings, insects or minerals. The few references in the literature describe these images as a unitary corpus, when in fact they constitute a rather heterogeneous group. We will be referring to four types of images.

The larger group is made up of thirty two woodcuts, based on images included in the book *Exoticorum libri decem*, by Carolus Clusius, published in 1605 in Leiden by the Plantin press. These illustrations feature next to many passages where Nieremberg either makes reference to Clusius or quotes directly from his text. Due to the similarities between the woodcuts in Clusius and Nieremberg's works, it is highly possible that the same woodblocks were used. Reusing older woodblocks had been and was still common practice in printing houses, either in preparation of further editions of the same book or editions of different works devoted to a similar theme.[8]

The second important group of images is made up of twenty seven woodcuts, which feature the signature of the Flemish engraver Christoffer Jegher, an important collaborator of Peter Paul Rubens.[9] Jegher worked for the Plantin-Moretus Press for almost two decades, until 1643, mostly devoted to the design of title pages for religious works. As part of Rubens' team of engravers, he was responsible for a sort of revival of the woodcutting technique, in a period, the 1630-1640s, dominated by copper engraving and etching. Mentioned somehow loosely in the literature about Nieremberg and the Hernández materials, Jegher's contribution to the visual content of *Historia Naturae* is more problematic that it seems. It is generally assumed that he was the author of *all* the woodcuts in the treatise. However, it is not possible to conclude that he was the only responsible for all the engravings. Even if we focus only on the images that feature his signature, Jegher's contribution is still problematic. To what extent is his production original, in the sense expressed by Laet in his letter? A close look at the images reveals that many of his woodcuts are just very close versions of other engravings. The figures are practically identical. In terms of visual content they are no more novelties than the woodcuts taken from Clusius. Some of them are even more outdated, for they are taken from books that were published much earlier than 1605. Other engravings by Jegher, however, do offer novel images.[10] Which leads to the question: which materials did Jegher use to produce his woodcuts? The generally accepted answer is that he based his designs on the original images of the Hernández expedition. This is, again, problematic. It is rather unlikely, though not impossible, that Jegher travelled to the Escorial to work with the original images. There is no record of his presence in Madrid at the time. Besides, Nieremberg's text does not include any reference that could suggest a sort of collaboration between the Jesuit and the engraver. So, on the whole, we do not know which materials (copies of the originals) Jegher used. It seems that the original images that he had access to were not many, and their provenance is unknown.

The third group of images is made up of six engravings without signature. Two of them represent two birds of paradise.[11] The first one is a slightly modified version of the woodcut published by Conrad Gessner in the third volume of his *Historiae animalium* –dedicated to birds–, from 1555.[12] Reproduced in many other books, this image was for a long time the most important visual reference of the bird of paradise. The second image is very similar to the first of five engravings of birds of paradise published by Aldrovandi in his *Ornithologiae* of 1599.[13] Interestingly, the original watercolour on which the

latter engraving was based –which is extant, and kept at the Aldrovandi Archives in Bologna– is identical to the image of the bird of paradise included in the so-called *Pomar Codex*, the illustrated album that Philip II gave to the physician and professor of *simples* in Valencia, Honorato de Pomar.[14] In fact, many images included in the *Pomar Codex* are similar to those kept at the Aldrovandi collection, which makes this an interesting case of circulating images: were they copies from the same source, or one group of images was based on the other?[15] The third unsigned image, which features the «reverse» fish or *gaicanus*, is based on a woodcut from the fourth volume of the history of animals by Gessner, published in 1558.[16] Also from this book, the fourth image represents the *mors piscis* or walrus.[17] The fifth one, which represents the *granadilla* or Passion flower –complete with the signs of Christ's Passion– constitutes a slightly modified version of a model of this plant that became very popular in the first decades of the seventeenth century –as in *Cultura ingeniorum*, by Antonio Possevino, for example, published in 1610.[18] Finally, the sixth engraving depicts the «queen of snakes» or «teuhtlacocauhqui», whose discussion opens the twelfth book of *Historia naturae*.[19] Quite significantly, this image is very similar to the one included in the *Mexican Treasury* regarding the same snake, a fact that suggests a form of iconographic transfer from one book to the other –a plausible hypothesis, given that most of the visual material for the Lincean edition was prepared, even printed, by 1628.[20]

Finally, the fourth group of images is made up of five botanical illustrations, which already in 1954 Germán Somolinos d'Ardois identified as «those featuring Amerindian iconography».[21] In fact, only three of them feature the «water» and «earth» pre-Columbian symbols, a testimony of the local artistry that was employed during the Hernández expedition. How did these images reach the press remains unknown. They could belong to the corpus of preliminary sketches that Hernández kept in his possession until his death, which eventually were used to decorate –in a sort of collage– one of the royal chambers at the Escorial, the «Sala del Mediodía». In any case, these illustrations constitute a rare instance of a hybridised pictorial representation in a book, in fact in a whole discipline, natural history, that relied mostly on Europeanized illustrations.

In Nieremberg's time, images circulated much better than the objects they were meant to represent.[22] Natural elements would suffer from corruption and decay, whereas images, as Giuseppe Olmi has pointed out, «furnished not only a complete non-corrupted picture of the specimen, but also one that was incorruptible over time».[23] Images bridged huge geographical and temporal gaps. They turned distant and inaccessible entities into visible and manageable objects of study. They allowed for an alternative for first-hand observation, especially if the image was made «ad vivum», from the natural.[24] As the letter from Johannes de Laet reveals, the presence/lack of original images in a book on natural history was a key feature. Images, more than texts, constituted the novelty factor of a publication: new knowledge was represented chiefly

through new images. Following William Asworth, certain images appeared and reappeared persistently in modern natural visual culture: they circulated through books, and through versions of these images in other books or, in fact, in other visual media, such as paintings.[25]

In this regard, the images in *Historia naturae* constitute a rather heterogeneous and slightly unusual corpus. Copies next to original representations; versions of older, *classical*, illustrations mixed with depictions featuring non-European, *pre-classical*, symbolism. There is a strong sense of disparity, eclectic accumulation: some images have travelled from far, others have not even left the printing house; some reflect the European-centred, book-based tradition of natural knowledge, other speak for decentred, peripheral, local, forms of knowledge-making.

More specifically, what can we say about these images? Firstly, their number. There are not that many engravings. The images from the Hernández expedition amounted to two thousand botanical illustrations. And those devoted to animals, birds, fishes or reptiles could add up to several hundreds. Nieremberg's books features seventy images only. Comparing this quantity with the visual content in the *Mexican Treasury* the difference is noteworthy.

Secondly, originality. As Laet rightly noticed at the time, most of the visual elements in *Historia naturae* are based on previous images. The novelty of the Hernández materials is mostly missing. «There are lots of them, and so different one from another with respect to colours and forms, leaves as well as flowers, that one cannot find anything more curious than this, and if published it would be a great contribution to medicine», Cassiano dal Pozzo wrote in his diary after examining the original illustrations kept at the Escorial.[26] Surely, Nieremberg's book does present some images of certain species for the first time in European natural history. But these are almost like exceptions, given the extraordinary amount of novel illustrations that could have been included.

Thirdly, quality. These engravings are woodcuts, a declining technique by the middle of the century. As it soon became clear to the Linceans, this was a rather limited method to portray the natural world. The choice of such a reputed engraver as Jegher may seem as the sign of commitment for good quality illustrations, but the end result is not as outstanding compared to Jegher's other works in collaboration with Rubens.

On the whole, the corpus of images in *Historia naturae* constitutes a poor, and to a great extent failed, iconographical and epistemic project. Among the reasons for this we could single out the lack of resources at a time of deep economic crisis in Spain, the lack of appreciation of these materials on the part of patrons –as Fernando Rodriguez de la Flor has argued, Spain, at this time, was in the process of turning into a «metaphysical peninsula», devoting itself to poetry, drama, painting[27]– and, more importantly, the type of difficulties the Linceans encountered: printing a large collection of ever-circulating images was a gigantic task. *Historia naturae*, in this regard, could be seen as a reflection of the contingent nature of knowledge-making practices in the first decades of the seventeenth century.

[25] William B. Ashworth Jr., "The Persistent Beast: Recurring Images in Early Zoological Illustration". *The natural sciences and the arts*, Allan Ellenius, ed. Stockholm: Almqvist, 1985, pp. 46-66. Even woodblocks circulated: just when Nieremberg's work was being printed, most of the Plantin-Moretus stock of woodblocks was not available, for it was in London, lent for the printing of the second edition of John Gerard's *Herball* (Imhof 1997).

Observatory of Scientific Communication, Universitat Pompeu Fabra, Barcelona, SPAIN
nuriap.perez@upf.edu

Abstract

Taking the Royal College of Barcelona (1760-1843) as a case study, this communication shows the development of modern surgery in Spain initiated by Bourbon Monarchy founding a new kind of institutions by means of its academic activities of diffusion of science.
Founded 250 years ago, in 1760, the Royal College of Surgery of Barcelona was the second college of surgery created in Spain. The new college was erected near the old Hospital of Santa Creu. Learning human bodily structure by performing hands-on dissections in the anatomical theatre has become a fundamental element of modern medical education.
Antoni Gimbernat worked with tenacity from Madrid improving the quality of the royal colleges in Spain, but before that, he was professor of Anatomy in the College of Barcelona and the most famous Spanish surgeon with international recognition.
Gimbernat favoured the study of natural sciences, the new chemistry of Lavoisier and the experimental physics in the academic programs of surgery. As a result of that, the academic program developed in the new colleges of surgery was different from the traditional formal education for surgeons. The new physician-surgeons trained there were not only interested in therapeutics, but also wanted to know as much as possible about the bodies' anatomy and physiology, being as they were in competition with its pathology.
According to the study of a very relevant set of documents preserved in the library, the so-called "Juntas Literarias", we have notice about the main subjects debated in these clinical sessions about the concept of human being and diseases in relation to the development of the new experimental sciences. These documents evidenced that chemistry and experimental physics were considered crucial tools to understand the unexplained processes that happened in the human body in a medico-surgical context.

Introduction

The development of modern surgery in Spain was initiated by Bourbon Monarchy founding a new kind of institutions by means of its academic activities of diffusion of science. Founded 250 years ago, in 1760, the Royal College of Surgery of Barcelona was the second college of surgery created in Spain[1]. The new college was erected near the old Hospital of Santa Creu. Learning human bodily structure by performing hands-on dissections in the anatomical theatre has become a fundamental element of modern medical education. Taking the Royal College of Surgery of Barcelona (1760-1843) as a case study, first of all, I am going to introduce the purposes and the aims for founding this kind of institutions in our country. After that, I am going to look a very relevant activity of communication of science performed at the college, the so called "Juntas Literarias"[2]. Because, it's through these scientific manuscripts preserved until nowadays that we know the reception and development of the new sciences well as its application to the healing arts at the end of 18th century in Spain. According to the study of this very relevant set of documents preserved we have notice about the main subjects debated in these clinical sessions about the concept of human being and diseases in relation to the development of the new experimental sciences. These documents evidenced that chemistry and experimental physics were considered crucial tools to understand the unexplained processes that happened in the human body in a medico-surgical context. Professor Antoni Gimbernat favoured the study of natural sciences, the new chemistry of Lavoisier and the experimental physics in the academic programs of surgery. Then we will have a look of the uses of the experimental physics applied to medicine[3]. According with that, first, I will summarize the theoretical facts, controversies and debates electricity aroused, a natural phenomena the origins of which remained unknown. Secondly, I would like to stress the instrumental use of this knowledge applied to medicine and its practice. Thanks to the works performed about this subject at that moment we will see the application of this knowledge in practice. The conclusions will be expounded at the end.

The Royal Colleges of Surgery as an enlightened innovation

Founded 250 years ago, in 1760, the Royal College of Surgery of Barcelona was the second college created in Spain[4]. This institution was erected next to the Hospital of Santa Creu, an age-old health institution founded in1401. The Hospital provided the college with patients and corpses to be studied. The development of modern surgery was determined by an increasing demand for medical well-trained personnel able to attend the soldiers on the various fronts open in Europe. The Royal College of Barcelona was founded in a country bordering France (Catalonia, located in north-eastern Spain) and occupied by Spanish military forces. The Royal Colleges of Surgery represented the most important enlightened medical institution created by the Spanish Bourbon monarchy.

Working with tenacity, Antoni Gimbernat improves the quality of the Spanish royal colleges from his position in Madrid. Before, he was trained as a surgeon in the Royal College of Surgery in Cadiz and then he was professor of anatomy in the College of Barcelona. Later on he will be the most famous Spanish surgeon with international recognition. Thanks to a Royal grant he visited France, Great Britain, Scotland and Holland. When he came back to Spain he was nominated director of the third Spanish college of surgeons, The Royal College of San Carlos in Madrid. Later on he became Royal Surgeon of Carlos IV.

Gimbernat, with a good position, favoured from Madrid the study of natural sciences, the new chemistry of Lavoisier and experimental physics in the academic programmes of surgery. The new physician-surgeons trained there were not only interested in therapeutics, but also wanted to know as much as possible about the bodies' anatomy and physiology, being as they were in competition with its pathology. As a consequence of that these new medical-surgeons were not only interested in therapeutics, but wanted to know as much as possible about the parts of the body and its function, its physiology and in front of the illness, its pathology being in competition with physicians.

Spreading science in a new scenario

The academic programme developed in the new colleges of surgery was different from the traditional corporative education for surgeons. In this setting, and in the same way as it was being implemented in other enlightened scientific institutions belonging to this period, for instance societies and academies, a new form of transmission of knowledge and in our case a new method of teaching as well, was proposed in the regulations of the new colleges of surgeons in Spain. The rules of the Spanish colleges of surgery established to hold the so-called "Juntas Literarias". This means the regulation favoured activities in which a dissertation was read periodically and, after that, censored in a public session in front of both the students and the board of professors of the college. So both professors and students attended the dissertations that were read periodically by the professor in front of the audience. Then, the following session, another member of the College Board assigned by the vice-president of the college was in charge of elaborating a critical assessment, reading in public session again plus a critical writing about the dissertation. At the end of the session each professor member of the board gave a short written assessment or comment.

It is important to stress that these manuscripts were never published, but fortunately are available in the archives and constitute one of the most important primary sources to know the role and the reception of the new sciences applied to healing arts.

Chemistry and allied sciences to interested audiences

Thanks to the regulations promoted by Antoni Gimbernat in 1795[5], chemistry and experimental physics were included in the academic programs of the Spanish Royal colleges of Surgery. According to "Juntas Literarias" documentation it is clear that chemistry became especially present in the dissertations expounded at the Royal College of Surgeons of Barcelona[6]. The first reference to chemistry found in the college's files dates from 1797[7]. It is a dissertation about the use of carbonic acid to remove gallstones from the urinary bladder. In effect, the development of the study of airs crossed the boundaries between chemistry, physics, and medicine. The so called "natural philosophers" studied some problems that led them into chemistry but also into domains outside the normal scope of chemical practice. For example, the therapeutic use of aerostatic balloons was subjected to discussion in the sessions at the Royal College of Surgery of Barcelona[8]. The pros and cons, controversies aroused by these and other topics given at the sessions (vaccine, tumours, galvanism, syphilis, etc.) are already present in this important set of documents. The "Juntas Literarias" showed in public session the topics which aroused controversy, expectation and anticipation in the Spanish enlightened society in those days.

Electricity: from chemistry to experimental physics

I would like now to discuss some details about the emergence of Experimental Physics at the Royal College of Surgery of Barcelona. First of all I am going to have a look at the theoretical facts leading to a debate about this subject in scientific sessions. Secondly I would like to show some dissertations presented at the sessions of the college and some works published in relation with that. And finally I would like to emphasize the uses of experimental physics applied to medicine.

Regarding the nature of electricity, it was included among the chemical principia of the bodies in the beginnings but after Alessandro Volta's experiments electricity was considered an inherent force of the nature. In the middle of the eighteenth century, the abbot and professor of experimental physics Jean- Antoine Nollet (1700-1770) defined electricity as something with both irritating and stimulating character simultaneously[9]. The electrical fluid and electricity were analogous in relation to light and fire. For this reason, some scientists thought that the origins of all of these elements should be the same. The experiments presented in the Royal Society by Henry Cavendish (1771-1772) or the public demonstrations by John

[9] NOLLET, Jean-Antoine (1746), *Essai sur l'electricité des corps,* París, Freres Guerin. Translated into Spanish in 1747 by Joseph Vázquez y Morales.

Hunter using torpedo fish led to think that electricity could be innate in living beings. In 1791, Galvani, professor of Obstetrics in the Italian university of Bologna, described how a frog muscle prepared for dissection was able to experience contractions when the crural nerve of this amphibious was connected to the metallic arc[10]. The new observed phenomenon was denominated "galvanism", "galvanic fluid" being a substance of the same nature as the "nervous fluid".

Both Galvani and Volta observing the same phenomena –the muscular contraction in frogs prepared for their dissection– reached different conclusions. It's the so-called Galvani-Volta controversy and the matter of the dissertation "On the muscular fibres" presented at the College in 1806. Galvani, physician and physiologist, thought that there was some kind of animal electricity inherent to the organization of living bodies and responsible for muscular contraction. The lack of an electrometer able to measure the minimal amount of electricity involved in this physiological phenomena made its demonstration difficult. From 1800 to 1805 Giovanni Aldini reproducing Galvani's experiments was able to produce electricity signals in animals without the aid of metals, which corroborated the hypothesis that living bodies could be considered as true batteries able to produce and to accumulate electricity. However, the physicist Alessandro Volta, thanks to an apparatus developed by himself, the so called battery of Volta, was able to induce muscular contractions experimentally. This fact reaffirmed the possible external origin of the phenomenon.

The expectation opened by the nature of electricity and its application to the healing art was present at the Royal College of Surgery of Barcelona according to the dissertations read in its meetings. At least I would like to emphasize two of them: "On Galvanism" read in public session in 1802[11] and "On the muscular fibres" read in 1806[12]. "On Galvanism" was written as an extensive review about galvanism where the novelties of electricity were expounded to the audience reviewing the main characters that had made its development possible (mainly Galvani, Perkins and Volta). "On galvanism" presented as a dissertation at the Royal College of Surgery of Barcelona explained the development of "metallic tractors" developed by Perkins and his son in 1798. They used electrified metallic needles to relieve several kinds of health disorders "drawing off the noxious electrical fluid that lay at the root of suffering". After the evaluation of Galvani's experiments, in the dissertation "On galvanism" the coexistence of two different types of death is proposed: the animal death in relation to the chemical principles that conforms the living bodies, and the death of the vitality related with the vital principles that animate living beings. In this context, electricity was intimately associated with vitality. Living beings had been used to identify the effects of electricity on animal economy. For that purpose and in spite of the ethical and political problems, the use of corpses of people condemned to capital punishment has been documented. These debates could constitute a good source of inspiration for Mary Shelley, author of the famous *Frankenstein* novel (1818)[13]. Alfred Smee (1818-1877) surgeon of the St. Bartholomew Hospital of London defended the theory according to which the bodies themselves could regulate the intrinsic electricity they had. For this statement he was the object of a lot of criticism. The Galvani–Volta controversy was exposed in the public session "On the muscular fibres" at the Royal College of Surgery of Barcelona, and that dissertation displayed in detail the structure of the battery of Volta applied to treatments. The reception of the theories of Galvani by the professors of the College was divided. Some of them manifested to be more in agreement with Volta's postulates; others with Galvani, others with the chemical changes proposed by Alexander Humboldt, and others expressed their scepticism.

Antoni Cibat Arnautó introduced experimental physics

In order to demonstrate the great importance of the literary meetings "Juntas Literarias" celebrated at the College I would like to show the statement of professor Antoni Cibat Arnautó (1770 -1812), in the preface of his work *Elements of Experimental Physics* (1804, vol. 1)[14]. According to him he had started his research on the effects of electricity in living beings and by extension on human beings at the Royall School of Surgery of Barcelona some years before. In his treatise, Cibat devoted more than 150 pages to electricity. In the afterwards of the book Cibat has a special mention to the scientific sessions performed at the college of Barcelona as crucial activity that configured his knowledge about experimental physics in general and about electricity in particular. At least we can find ten manuscripts related with that subject. These documents contains both some practical aspects related to electricity applied to healing art and some theoretical parts contextualizing this new and controversial corpus of knowledge.

[14] CIBAT, Antoni (1814-1815), *Elementos de Física Experimental*, Barcelona, Antonio Brusi. 2 vols.

However, Cibat and his colleges had tried to reproduce the crucial experimental works performed by Galvani, Volta, Aldini, Humboldt and others in his laboratory, he explains in his textbook. From 1798 to 1792, Cibat studied surgery at the college of Barcelona. After that, he went to Scotland and he obtained his PhD at the Marischal College in Aberdeen[15] and later on he came back to the Royal College of Barcelona again and was professor of Experimental Physics from 1797 to 1807. At least two dissertations in 1798 and in 1799 about the utility of electricity in the healing art had presented by professor Cibat in *junta literaria*. Despite the fact that Cibat was a defender of Galvani's postulates, he specifies in *Elements of Experimental Physics* the difficulties with the achievement of the results obtained by his predecessors. Cibat and his counterparts tried to reproduce the same experiences, trying to verifying his works at the laboratory, unsuccessfully.

Instrumental uses of electricity and devices applied to healing arts

At this moment, following the works mentioned before some illnesses were considered caused by some electricity dysfunction in the human body. For that reason professor Cibat devoted his research to the study of this subject. In his opinion, some kind of illness convulsions and trismus were caused by an imbalance of electricity in the body[16]. Trismus is defined as a tonic contraction of the chewing muscles, moreover in the past this word was often used to describe the effects of tetanus. Whenever electricity was in excess in the jaw a trismus could appear as a consequence of an imbalance of electricity in the body. More recently, this term has been used to describe any restriction of the mouth opening, including restrictions caused by trauma, surgery or radiation. On the other hand, a convulsion is a medical condition where body muscles contract and relax rapidly and repeatedly, resulting in an uncontrolled shaking of the body. The manuscripts of the sessions contain a lot of information about the therapeutic uses of electricity. I would like to stress the instrumental use of this knowledge applied to healing art. One episode is described in detail by Cibat: some electric discharges were applied to a patient thanks to an electrostatic machine near the sea. Moreover, in his dissertations he describes several procedures of electrification applied to several parts of the body depending on the illness that he wanted to treat. Cibat in his *Elements of Experimentals Physics* explained when electricity should be applied, extracting or adding this substance according to the disease and depending on the illness and if it was in excess or not. He considered this kind of procedures as a suitable alternative to other treatments. In general, therapies using electricity aim to counteract the unhealthy problem related to electric imbalance in the human body.

Electrostatic machines became part of the healing arts when Van Martinus Marum said: "the history of electrical science teaches us that progress in this science has been made in step with the use of ever larger electrical instruments giving a more powerful electrical force". Some machines described by Pieter van Musschenbroek in his book *Essai de Physique* (1751), were reproduced by Spanish artisans directed by Jaume Bonells, physician and deputy director of the Conferencia Físico Matemática Experimental, predecessor institution of the Royal Academy of Natural Sciences and Arts of Barcelona, founded in 1770. In one of his dissertations, Cibat states that Antoni Gimbernat had contracted artisan members of the above mentioned institution in order to build specific instruments for the Royal College of Surgery of Barcelona. Juan González Figueras (1731-1807) was the most famous artisan not only in Catalonia but in Spain, and his well-known skills were spread in the Spanish generalist newspapers. Several dissertations presented at the College contain technical information about description and maintenance of this kind of devices, always in the context of the healing arts.

In summary, in the middle of the 18th century all the elements required for the emergence of a new discipline, Experimental physics, was present at the Royal College of Surgery of Barcelona. In Spain, as well as other developed countries, for instance Italy, France, England or Scotland; theoretical facts and practical uses were taken into account. Expectation opened by the nature of electricity and its application to the healing art was present according to the dissertations read in the meetings performed in the College.

To conclude

Taking the Royal College of Surgery of Barcelona (1760-1843) as a case study, after I introduced the purposes and the aims for founding this kind of institution in our country I made special mention of one relevant activity of communication of science held in these institutions, the scientific sessions called "juntas literarias". As I tried to demonstrate, among others documents available, through this manuscripts –the "juntas literarias"– we have noticed the development of this new discipline in Spain: the emergence of Experimental Physics and its reception always in accordance with international

Ms. 67, Bundle 8, University of Barcelona. [12th July 1799].

development of this new discipline at the end of the 18th century. The experimental physics application to healing arts was associated with the expertise, managing and maintenance of electric machines and devices. Despite the controversies and theoretical debates aroused by electricity, its use for therapeutic purposes has been shown. Its development required both the knowledge for its construction and maintenance of new instruments as an essential condition for its application to the healing art. The emergence of experimental physics was in parallel with the development of the new chemistry of Lavoisier. Since chemistry and experimental physics were included in the academic programs of the Spanish colleges of surgery this kind of knowledge was considered a crucial tool to debate and to understand the unexplained processes that happened in the human body in health as well as in illness. This subject of debate occurs just when the legitimization of surgery in the healing art is being consolidated. In this setting, the new concepts of chemistry and experimental physics constitute instrumental knowledge for understanding the observed phenomena which happened in healthy human bodies as well as in illness condition, with respect to anatomy, physiology, pathology and therapeutics.

CIRCULATION AS TRANSLATION OF BOOKS: THE CASE OF ARDINGHELLI IN 18TH-CENTURY NAPLES

Corinna GUERRA
Università degli Studi di Bari, ITALY
cori.g@hotmail.it

Abstract

In 1727 Stephen Hales published the seminal work Vegetable Staticks *which initiated a new idea of the "air": no longer a mere physical instrument, but rather a chemical capable of binding. Most of Italian scholars probably learned that by the first and only Italian translation published in Naples in 1756.*
In fact, in 18th-century Naples there was a brilliant young woman, whose name was Mariangela Ardinghelli (1728-1825), who had already dedicated herself successfully to translating Hales since 1750, when she was only 22 years old. Indeed, she had even published the Italian text of Haemastatics *(1733), becoming somewhat famous amongst scholars and we know that all foreigners in the Kingdom of Naples wanted to meet her. She was in contact with numerous academies and in her salon lively conversations, of Newtonian inspiration, took place.*
So Ardinghelli had a central role in the circulation of many scientific books in Italy through her translations; with her notes added to the text she also fit the theory to her local context converting, e. g., all English weights and measurements into their Neapolitan equivalents.
Ardinghelli is also linked, in the history of the circulation of ideas and techniques, to the 18th century fashion for electricity: she was the addressee of the Abbé *Nollet's first* Lettres sur l'electricité *(1753) and for the whole life she informed him about scientific news from Naples.*
This paper reveals Ardinghelli's peculiarities and her role in circulation, reception and appropriation of scientific theories in the Kingdom of Naples (i.e. Southern Italy), through an analysis of her writings and of those (both coeval and later) who wrote on her.

In 1727 Stephen Hales[1] (1677-1761), the famous English physiologist, published the seminal work *Vegetable Staticks*[2] which initiated a new idea of the "air": no longer a mere physical instrument, but rather a chemical capable of binding. Most of Italian scholars probably learned that by the first and only Italian translation published in Naples in 1756.

[1] GUERLAC Henry, *The continental reputation of Stephen Hales*, in «Archives internationales d'histoire des sciences», n. 15 (1951), pp. 393-404.

In fact in 18th-century Naples there was a brilliant young woman, whose name was Mariangela Ardinghelli (1728-1825), who had already dedicated herself successfully to translating Hales since 1750, when she was only twenty two years old. Indeed, she had even published the Italian text of *Haemastatics*[3] (1733), becoming somewhat famous amongst scholars, and we know that all foreigners in the Kingdom of Naples want to meet her.[4]

Ardinghelli is one of the women-scientists whose fame has reached us just because they devoted themselves to the translation of scientific works; in this way we also have the opportunity to rediscover her role in the European debate about electricity.

In 1749 she met the famous Jean Antoine Nollet[5] who provided Ardinghelli with her first ‘professional’ contact with the European scientists such as Darthenus, Jean Baptiste Le Roy (1720-1800) and Jean Jacques d'Ortous de Mairan (1678-1771), with whom she later exchanged letters. Nollet himself relates in his travel journal that during one of their first meetings Mariangela gave him a couple of geometrical problems to be solved by Alexis Claude Clairaut (1713-1765).

In fact, her correspondence with S. Hales, who we can reasonably call “Her Author”, started after the publication of her *Haemastatics* translation in 1750, when he sent her all his works in the hope she would translate them.[6]

According to Ardinghelli's nephew, when they met, Nollet was the Dauphin's tutor. Along with the Marquis de l'Hôpital[7], to whom Mrs. Ardinghelli dedicated her *Haemastatics* translation, he tried to get her to come to Paris as the tutor to the King's daughters, but her mother kept her in Naples.[8]

In 1753 Nollet addressed her the first of his famous *Lettres sur l'electricité*[9]. At least seventy letters of their private correspondence have been lost. In several *memoires* of the *Academie des Sciences* Nollet mentions news and words written by his Neapolitan correspondent, such as when he was informed by her about curious medical cases examined by Doctor Carlo Curzio, which Nollet had translated and published in France[10].

At this point, it is finally possible to say something about her famous translation of *Haemastatics or, an account of some hydraulic and hydrostatical experiments made on the blood and blood-vessels of animals. Also an account of some experiments on stones in the kidneys and bladder*. It does not intend here to go deeply into the well-known and, to some extent, already studied contents, since they don't help to clarify the role of the translator activity as a medium for circulating scientific ideas, but it is important to remember that she translated from the French version.

In Mariangela Ardinghelli's opinion, translating means correcting mistakes too, to avoid the danger of transmitting wrong scientific contents or the thinking of the French translator to the Italians readers. So where the French text does not make any sense, she consults the original English to discover that whole lines are missing. François Boissier De Sauvages[11] (1706-1767), translating the same text into French, changes the English units of measurement into French ones, without modifying the correspondent numerical values. She calculates all the equivalences again, and since she realizes most of

them are wrong, she feels free to correct them. Sometimes she says she has paraphrased instead of translating, because the concepts are too difficult and she thinks they may be misprints. Moreover, she informs the readers that she has added a few notes in italics for her own explanations.

> Translating Mr. de Sauvages's notes, I tried to clarify them wherever possible; but I wasn't always able to do that, because this Editor sometimes is not very clear. He says few things that belong to the text; his main purpose is to restore the ancient system, according to which spontaneous motions of the body derive from the Soul.[12]

In the second volume, published two years later, where she translates some of Hales' writings on kidney stones there seems to be a willingness on her part to communicate a social message, in this case as a translation of a scientific work. As Ardinghelli explicitly says, her aim is to enable a wider public to benefit from the medication for kidney stones and «in order to make it easier for those who would like to use this medication, I have converted all English weights and measurements into their Neapolitan equivalents.»[13]

On page 39 (volume 2) of her translation, she personally examines Neapolitan water sediments as Hales have done for the water sediments around London. She reports with a degree of frankness to have used a candle kept in a kind of small stove and accurately describes it. As far as she knows, no one has done this before, so she decides to do this just because it would have been pointless for her readers to know only about the far away city of London.

Then in 1756 Ardinghelli published *Vegetable staticks and analyse of air*, and although only twenty years later, in the 1776 edition, her name appeared on the title page. This time she translates directly from English and, when in doubt, she looks at Buffon's French translation. In this second edition she does all the calculations again. She repeats the experiments, reports Newton's Latin passages, and changes into 'Neapolitan' all the words for animals and plants so that everyone can recognize them.

It is interesting to note her intuition, which is the base of Hales' importance in modern chemistry, on p. 246 note (m)

Air did not only have a physical but also a chemical property; no one had thought about air before; why, she asks, has no one noted that air combine with other chemicals?

> It is sure that many useful discoveries come from physicians in natural history, if they go on working in these so smart new Hales' experiments on "air". But no one I find, who has tried to repeat or to study on them until today, neither to reflect on the general system, erects on them.[14]

This is exactly what Antoine Laurent Lavoisier (1743-1794) would do some years later, and what pneumatic chemistry had done before him, which was to bring on the famous Chemical Revolution. However, if we reflect for a minute on the fact that Lavoisier didn't understand English and came to know Hales through Buffon's translation into French, then Ardinghelli's work looks even more significant to our eyes.

Ardinghelli's only real scientific acknowledgment came from the 'Accademia dei Fisiocritici' of Siena[15] (Tuscany). In 1759, in line with the new 18th-century spirit, the Academy accepted a woman, the *celebrated philosopher* Mrs. Ardinghelli, who soon sent a letter to express her gratitude (July 2, 1759)[16].

It is unlikely that Ardinghelli worked on anything for the Academy of Siena. In the Academy dissertation indexes I've consulted there is nothing about or by her. But thanks to this admission, Mariangela Ardinghelli could finally put a title to her long and valued scientific activity in her latter publications, poetical compositions for public events.

HALES Stephen, *Emastatica, o sia Statica degli animali: esperienze idrauliche fatte sugli animali viventi dal signor Hales... tradotta dall'inglese nel franzese, e commentata dal signor De Sauvages... e dal franzese nuovamente trasportata nell'italiano idioma*, Napoli, presso Giuseppe Raimondi, 1750-1752, vol. 1, *A chi legge*, without page number.

[13] Ivi, vol. 2.

[14] "Egli è certo, che molte utilissime scoperte potrebbero fare i Fisici nella Scienza Naturale, se colla scorta di questa ingegnosissime nuove Sperienze del Signor Hales travagliassero intorno all'aria. Pure nessuno io ritrovo, che siasi sinora applicato né a ripeterle, né ad esaminarle, né a riflettere al general sistema, ch'egli sopra vi fonda." HALES Stephen, *Statica de' vegetabili, ed analisi dell'aria... tradotta dall'inglese con varie annotazioni*, Napoli, nella stamperia di Giuseppe Raimondi, 1756.

[15] The *Accademia dei Fisiocritici* was founded in Siena in 1691 by Pirro Maria Gabrielli (1643-1705) its venue was the Hospital "Santa Maria della Scala".

[16] Archives of the Accademia dei Fisiocritici, Correspondence, 1759, 156 [12] in TROMBETTA Vincenzo, *Storia e cultura delle biblioteche napoletane*, Napoli, Vivarium, 2002, p. 89, n. 42.

De Lalande claimed that she had also written some works about physics, which were not published because of her modesty, and that she started to translate De Buffon's *Histoire naturelle*. These are words we can trust, since the French astronomer had a long correspondence with her, which is also proved by the mentions she makes of him in the few letters still available.

Another manuscript attributed to Ardinghelli is now in a miscellaneous volume in the library in Palermo of the Società siciliana di Storia Patria[17]. The title is *Dissertazione del Sig.r D.n Giuseppe Sembrano sopra il Trattato del Movimento degli Animali, nell'opera del Sig.r Gio' Borelli*[18]. We cannot be certain Ardinghelli wrote this or not, but her notes in *Haemastatics* show familiarity with Borrelli's work.[19]

We have to admit that Ardinghelli's choice is translating Hales' works is connected to her intent of arousing greater interest around Newtonian philosophy, and that translation allowed Mariangela Ardinghelli to show her skills as a mathematician and experimental scientist to a wider audience than that of the Spinelli Library, which was the place where she had her scientific education. It was a Public Library which was owned by Prince Ferdinando Vincenzo Spinelli of Tarsia (1685-1753). On occasion of its opening, Mariangela, who was seventeen at the time, (July 22, 1747) is said to have given a highly praised speech in Latin on 'electrical force'. De Lalande described the sumptuous Spinelli Library as unique, due to the great number of books and to its scientific apparatus, even better than those owned by the University, but the French traveler adds, that even if the library was open three days a week, both in the morning and in the afternoon, its librarian was often alone: maybe Ardinghelli was alone with Hales' books too.[20]

So it's undeniable that translation and study of languages were for her the only means she had of living as a scientist beyond the Kingdom's borders, outliving herself, and above all the activity of translation was her best means to circulate new scientific ideas and to validate her Newtonian belief among Italian scholars.

After the effort of calculation, translation and experimentation Mariangela Ardinghelli used to conclude her forewords with these beautiful words:

> Take pleasure now in my work, if you find it worthy of your pleasure. And live happy.[21]

CORRECTING LAZZARO SPALLANZANI. ANTONI MARTÍ I FRANQUÈS' CONTRIBUTION TO THE KNOWLEDGE OF SEXUAL REPRODUCTION OF PLANTS (18TH CENTURY)

Pasqual BERNAT
Centre d'Història de la Ciència (CEHIC), Universitat Autònoma de Barcelona, SPAIN
pasqual.bernat@hotmail.com

Abstract

In Expériences pour servir l'histoire de la génération des animaux et des plantes *(1786), Lazzaro Spallanzani (1729-1799) concluded that some plants, including hemp, could reproduce without fertilisation. Antoni Martí I Franquès (1750-1832), a Catalan naturalist, repeated Spallanzani's experiments with hemp, concluding that the Italian scientist was wrong. According to Martí, Spallanzani had not been sufficiently rigorous and careful in his testing. He did not realise that there were male or hermaphrodite flowers present in the female plants. Martí found that the intervention of both sexes was needed for successful reproduction in hemp, as in all superior plants. At that time, experiments on plant sexuality were crucial to make a definitive determination among the three alternatives surrounding the mechanism of generation: the ovist theory (pre-existence of germs in the egg), the animalculist theory (pre-existence of germ sperm) or epigenesis (meeting-with-fertilisation of two principles contained respectively in the egg and the sperm). In this paper, we shall outline Martí's method and explain how he reached his conclusions.*

The sexual theory of plants. The debate during the 18th century

The debate on plant sexuality is a long, controversial episode in the history of science. From the ancient world until its proof well into the 19th century, theories in favour of plant sexuality were put forth, certified by experiments that seemed definitive but that were soon rejected by other experiments which also purported to be definitive. Indeed, plant morphology itself did not do much to help resolve the issue. We should bear in mind that in the majority of plant species, the male and female organs are together not only in a single stem but also in a single flower, thus making it more difficult to clarify any kind of sexuality based on two genders. Until the exact meaning of stamens and pistils was recognised, it was very difficult to properly interpret a state of hermaphroditism, which can only be noted exceptionally in animals. And this was coupled with many botanists' persistent predisposition to deny sexuality in plants. Along these lines, we can find an early argument in the Aristotelian tradition which encompassed scientific activity throughout many centuries that denied the existence of sexuality in plants. Furthermore, the majority of botanists' preference until well into the 19th century was for systematic studies, relegating physiological questions to secondary status. Indeed, in the midst of the 18th century Linnaeus himself, a prince among botanists, distinguished "true botanists" that is, those who worked on the classification, systematics and description of the different plant species, from "botanophiles", amateurs who were only concerned with secondary, accessory issues, such as plant physiology, fertility and sexuality.[1]

Even though plant sexuality had been guessed at since the ancient world, no experimental confirmation was available until the late 17th century. In 1694, Rudolph Camerarius (1665-1721), a Botany professor at Tubingen, wrote *De sexu plantarum epistola* in which he set forth the list of experience which led him to conclude that stamens are male sexual organs while the style and ovary are the plant's female organs. He also noted that there could be no production of fertile seeds unless both sexes took part in the fertilisation process.[2] However, the fact that this process of fertilisation was not wholly clarified and that some of Camerarius' experiments yielded results that seemed contradictory meant that the sexual theory never gained ground and the controversy instead endured throughout the entire 18th century. Even though a respected authority like Linnaeus acknowledged the existence of sexes in plants and founded his system on observations of stamens and pistils, the detractors from the sexual theory argued strongly against it, reaching their maximum success in the opinions of Lazzaro Spallanzani (1729-1799), who used an implacable battery of experiments which cast doubt on the sexual theory in the late 18th century.[3]

Even though Spallanzani had noted that in a vast number of cases, when isolated from the males of their own species, female plants blossomed without producing fertile seeds, he also observed some cases that contradicted this rule. His first results came from hemp (*Cannabis sativa*). Spallanzani cultivated two female stems of this plant isolated in a closed chamber in order to prevent any contact with pollen that might come from a male plant. To further secure this isolation, he even placed several blossoming branches from these female stems, with their flowers still closed buds, in bottles with the necks sealed with plant resin. Despite these conditions of extreme isolation which made contact with pollen impossible, the majority of the seeds produced were fertile. He conducted experiments with similar results using spinach (*Spinacia oleracea*) and mercury (*Mercurialis annua*). In order to reject any objection due to the possible arrival of pollen through the wind or insects, or the fact that the stamens that are sometimes found in female flowers were ignored, Spallanzani chose the watermelon (*Citrullus lanatus*) as his new subject of experimentation, whose flowers are large enough to prevent this kind of error. After eliminating the male flowers, he still obtained fertile seeds. To demonstrate that there had been no contamination from external pollen, he cultivated watermelons in a greenhouse in the middle of winter, when no male flower could exist in this season outside the greenhouse. In this case, too, the experiment yielded fertile seeds. With these results, Spallanzani, who was becoming one of the most reputed experimenters at that time, sowed serious doubt as to plant sexuality among the natural philosophers of his day. At the same time, this doubt opened the doorway for new studies and experiments to prove the certainty of the Italian scholar's results. The curious spirit of our main character, Antoni Martí i Franquès, set out to cross the threshold of this door with his own experiments. However, before embarking on a description and analysis of Martí's experiments, let us learn more about this naturalist.

Antoni Martí i Franquès: Brief biographical sketch

Antoni Martí i Franquès was born in Altafulla on the 14th of June 1750. He was the son of Antoni de Martí Gatell, a landowner and businessman, and Maria Franqués Gatell, who was also from a wealthy landowning family.[4] After his primary school, guided by tutors who went to his house, at the age of 14 he entered the University of Cervera. This university experience was apparently not fully satisfactory, as we have proof of no degree that would enable us to verify his completion of any kind of programme at this educational institution. Therefore, we must choose to think that the vast knowledge that Martí demonstrated having was achieved through his own means. Apart from a deep-seated knowledge of Latin and Greek, he was also quite familiar with French, German, English and Italian, which over the course of his life would serve him as instruments for acquiring new knowledge from foreign publications and for interacting with scholars from other European countries. From a very young age, he revealed an inclination to study the natural sciences, especially botany and chemistry. He thus applied to join the Royal Academy of Sciences and Arts of Barcelona, a dream which came true in 1786. Shortly thereafter, in 1790, he was also admitted to the Royal Academy of Medicine of Barcelona as a free member. A businessman, he administered his family wealth, which encompassed vast tracts of vineyards and hemp fields, as well as numerous investments in textile factories and other commercial enterprises. He participated in the flurry of activities aimed at spurring the economy, such as the 1787 creation of the Economic Society of Friends of the County of Tarragona, the project to build a motorway between Tarragona and Lleida and the Drawing and Sailing School of Tarragona. Committed to the historical

[2] A good description of Camerarius' experiments can be found in the classic Sachs, 1890.

[3] You can track Spallanzani's experiments on plant reproduction in Spallanzani, 1784.

[4] For the biographical details of Antoni Martí i Franquès, see: Quintana, 1935 and Rovira, 1982.

events of his day, he economically contributed to defray the expenses caused by the military mobilisations during the Great War against the French Convention and participated actively in the patriotic movements and institutions during the French War. In fact, he was injured in a leg in this latter conflict. Antoni Martí i Franquès died in Altafulla on the 20th of August 1832.

Martí always kept abreast of everything that happened in the world of science in his day. With this purpose in mind, he amassed a fantastic library containing the most recent works in physics, chemistry and botany. His library also contained the leading works from classical literature as well as a number of treatises on agriculture, philology, geography and other disciplines (Duch, 1998), a veritable corpus of knowledge that reflects Martí's wide range of intellectual interests. He was also an avid reader of the top scientific journals circulating throughout Europe at that time. He regularly read journals like *Annales de Chimie, Annales de Chimie et de Physique, Journal de Physique, Archives des decouvertes, Journal des nouvelles étrangères et politiques, Le Publiciste, Magasin Encyclopédique de Nivose* and the science bulletin of the *Société Phylomatique* (Quintana, 1935). The friendships that Martí had cultivated with Parisian booksellers such as Girard, Freuttel and Fuchs, as well as others from Perpignan, proved to be highly instrumental to him in keeping abreast of the latest developments in the scientific literature (Quintana, 1935).

However, Martí was not contented to only examine the theoretical aspects of science, as many of his contemporary intellectuals and even some professors of the scientific disciplines were. Instead, he wanted firsthand proof of what he read in books and journals. To this end, he mobilised into action, making observations and experiments to check the results reported in the scientific stories published in the journals. This practice led him to ask new questions that could only be answered by new experiments. Martí thus became a modern scientist, with experimentation as the foundation of his working method. He conducted his experiments in his houses in Tarragona or Altafulla, and his venue was a laboratory equipped with the instruments needed to rise to the challenges posed by experimentally verifying the results. This experimental proof was what led him to detect anomalies in certain results published by European scientists who set forth their theories. Martí was not above checking what was being claimed in the scientific debates that were the subject of controversy Europe-wide. Two examples of Martí's desire to participate in the scientific discussion of his day can be found in the debate on the composition of the air in the atmosphere[5] and the mechanism of plant sexuality. The latter subject is the focal point of this study, which we shall now analyse in detail.

Antoni Martí i Franquès' experiments

Indeed Martí, who had read the study in which Spallanzani explained his experiments, and who was totally cognizant of the European debate on the sexual theory of plants (Quintana, 1935), designed and conducted an entire series of tests with hemp and other plants to check whether the Italian cleric's results were valid or erroneous.

He reported on these experiments and their results in the report he submitted to the Royal Academy of Medicine of Barcelona in 1790 (Martí, 1790). According to Martí himself, the reasons inspiring him to embark on this experimental endeavour were first the importance of the issue itself, secondly its possible application to agriculture and thirdly and most importantly the possibility of proving or disproving Linnaeus' ideas on plant sexuality. In this latter sense, throughout the entire report Martí came out strongly in favour of the Swedish botanist, often citing his work on plant mating. Linnaeus' experiment with hemp, whose results contradicted those of Spallanzani, were precisely what picked Martí's curiosity, spurring him to check for himself which natural philosopher was right. The easy availability of the hemp plant on Martí's own estates even further predisposed him to take a step towards securing his own proof.

Martí's series of experiments began simply by sowing hemp seeds in two pots. When the plants emerged and began to blossom, Martí eliminated all of the male stems and the stamens that appeared in some female flowers. By doing this, he aimed to ensure the absence of male elements in the stems. The first round of flowers wilted without being fertilised. However, the second round, which had dovetailed with the natural blossoming of the hemp fields around Martí's home, ended their cycle with the majority of specimens fertilised. According to Martí, the first flowers did not have the chance to be fertilised because there was no pollen anywhere. The second ones did because the wind carried this pollen from the nearby hemp fields, only 55 feet steps away, to the place where the experimental plants were located. To these results he added his own observation in the hemp fields, where when the male specimens were lacking, the female specimens remained unfertilised. To Martí, this fact was striking proof of the need for pollen in order for the hemp plant to be fertilised.

To reinforce this idea and discard the influence of environmental circumstances in the process of fertilisation, Martí came up with a new test which consisted of cultivating hemp plants in pots placed under different conditions. He placed a pot with male and female specimens in a window facing north and another pot with only female specimens in a window facing south. The plants were thickly sown in the first pot, while there were only four specimens in the second pot. It was understood that the northern exposure thick with plants would entail less favourable conditions than those in the second pot, which faced south and left room for all the specimens sown. The experiment began in late September, when the hemp plants

[5] On Martí's participation in the debate on the composition of the air in the atmosphere, see: Quintana, 1935 and Grapí, 2001.

on the estate and nearby plants had been harvested; therefore, the only pollen influence could come from the stamens of the male specimens in the pot facing north. With all of these conditions, the plants in the pot facing south, isolated and away from the pollen in the north-facing pot, yielded no fertile seeds, while the specimens in the north-facing pot did. Martí deduced that better or worse cultivation conditions did not matter as much; rather that what really made hemp plants fructify was the presence of male specimens. He confirmed this idea by artificially forcing fertilisation. With the pollen removed from the male stems in the north-facing pot, he inoculated the flowers in another series of female plants, also facing north and got almost all of them to yield fertile seeds.

Given these unanimous results in favour of the sexual theory, Martí provided several explanations interpreting Spallanzani's results. He recalled that in his experiments, Camerarius had obtained fertile hemp seeds in isolated female specimens, a phenomenon that he attributed to the arrival of pollen from nearby hemp plants carried by the wind, or to the presence of male flowers in these same stems. However, Spallanzani had taken the precaution to confine the female stems in glass containers, which were impossible for any male influence to penetrate. Martí, then, could only explain the fertilisation of the female flowers subjected to this confinement by the inadvertent existence of male flowers. He noted that as the result of constant, methodical observation, he had discovered male and hermaphroditic flowers in the female stems. He claimed that this phenomenon might have escaped Spallanzani's notice.

This particular hemp flowering had yet another possible source of error. According to Martí, there existed the possibility of fertilisation in very early stages of blossoming. Very young female flowers might be fertilised by also young male flowers. He proved this with an experiment in which he placed a pot with a female stem with incipient flowers near a pot with male stems whose flowers were also just beginning to bud. The female flowers that were exposed to the young males yielded fertile seeds despite the precociousness of their sexual relations. In this sense, Martí cast doubt on one of Spallanzani's own experiments which he claimed yielded fertile seeds from female stems separated from any male flowers, which had in turn been eliminated in a very early stage 18 days earlier. With the help of artificial fertilisation, Martí fertilised female flowers, yielding seeds that he never demonstrated to be fertile before 23 days after conception, and which achieved their maximum fertility one month after they were inoculated with pollen. With this experiment, Martí noted that Spallanzani's fertile flowers must have been fertilised before he eliminated the male flowers in a period longer than 18 days when even though the male flowers had not manifested their sex with all their attributes, incipient yet active pollen had undertaken its reproductive mission.

Martí used the technique of artificial fertilisation to reinforce the sexual theory. He fertilised female flowers chosen from a group subjected to isolation from any male specimen. The fact that these fertilisations yielded fertile seeds and that he observed that the flowers that had not been inoculated remained sterile were yet further arguments questioning Spallanzani's claims, thus reinforcing the idea of the universality of the necessary participation of both sexes in the reproduction of hemp.

Martí also experimented with other plants. He was unable to get an exclusively female specimen in spinach. When he eliminated the male flowers, they soon reappeared again. For this reason, he was unable to demonstrate that a totally female specimen remained infertile when isolated from the male influence. However, he did observe that in the lapse of time between when the male flowers were eliminated and when the new male flowers reappeared, the pistils of the female flowers on the same specimen lengthened further than normal when the female flowers were accompanied by male flowers. He had also observed this phenomenon in hemp, and Martí attributed it to the virginal condition of these flowers, which demonstrated, to his mind, the female flower's reaction to the absence of pollen. Somehow, with these observations Martí noted a natural "need" for complementation between the sexes, yet further corroboration of the sexual law in plants.

Spallanzani's experiments with watermelon, melon (*Cucumis velo*) and pumpkin (*Cucurbita melopepo*), all of them species with large enough flowers to facilitate their identification, confirmed cases in which female specimens totally isolated from the male presence managed to produce fertile seeds. With the goal of checking these results himself, Martí observed the blossoming of these plants, noting that at least in the southern latitudes of Altafulla, all three species contained what appeared to be female, male and hermaphroditic flowers in their stems. He placed special emphasis on the case of watermelon, a species in which, though quite rare, some male flowers could be found in female stems, which cast doubt on the purported total isolation to which Spallanzani claimed to have subjected the female flowers of this species in his experiments.

With this series of experiments and observations, Martí cast doubt on the experimental apparatus that Lazzaro Spallanzani had wielded several years earlier to question the sexual theory of plants. Spallanzani had also taken this questioning to the animal kingdom, relativising or even denying the role of male seminal agents in the process of fertilisation. Always cautious and respectful of Spallanzani, Martí noted the particularities of the blossoming of the plant species used in his experiments. These particularities made it more difficult to identify the flowers and made it necessary to conduct a painstaking, exhaustive exploration of the female stems in order to discard the possibility of any intruding male flowers. Implicitly yet with the solidity of experimental results that disproved the arguments wielded by Spallanzani, Martí was capable of correcting him and pointing to the possible causes of error. These errors lay in the "careless" or at least not very attentive action of a skilful and highly reputed experimenter who had not paid enough attention to detecting male flowers in the specimens which he believed only had female flowers. Without wanting to enter into the debate of the pre-existence of embryos, Martí never stopped questioning this interpretation of the reproductive process of living beings. The results of his experiments confirmed the need for pollen to take part in the reproduction of the plant species that Spallanzani himself had used precisely to evaluate the pre-formation of organisms in the "eggs" of the females. Somehow this was an empirical discrediting of a debate to which Martí supplied arguments which, precisely because they were also empirical, were difficult to discredit. For all of these reasons, we must regard Martí's contributions as retold in his report on the sex of plants as an important milestone in clarifying the mechanisms of reproduction in plants. Despite the fact that these contributions were not widely disseminated among the European scientific community of his day, these contributions were joined by those that strove to reveal the mechanisms governing life using the strictest experimental practice.

NEWTON'S QUEST FOR A MATHEMATICAL-DEMONSTRATIVE OPTICS

Steffen DUCHEYNE
Centre for Logic and Philosophy of Science, Universiteit Gent (UGent), BELGIUM
steffen.ducheyne@ugent.be

Abstract

In this talk, I take up and develop the suggestion made by the late I. Bernard Cohen, Casper Hakfoort and Alan E. Shapiro that Newton's methodological ideal of "deducing causes from phenomena" was not equally attainable in the study of optical phenomena. If this suggestion is correct, then in the apex of Newton's optical researches, The Opticks*, which in fact contained a set of interrelated theories on optical phenomena, Newton failed to rigidly deduce these theories in the sense he had done in the* Principia*.*

By contrasting Newton's methodology in the Principia *with the way in which theoretical conclusions are established in* The Opticks*, I shall be able to explain why Newton was less successful to accommodate optical phenomena according to his own methodological desiderata of deducing causes from phenomena. After having commented briefly upon Newton's methodology in the* Principia*, I will review the kinds of trouble that Newton ran into when trying to methodize optics in a Principia-Style fashion. My focal point will be Newton's arguments for the thesis that white light consists of rays differently 'refrangible'. Special attention will be paid to Newton's presumed application of Rule II of the* regulae philosophandi *in establishing that part of his optical theory. It is shown that Rule II licenses the identification of instances of causes of the same kind which have been shown to be true and sufficient to explain their phenomena. Thus, on the basis of Rule II we identify two instances of causal parameters of the same kind, which have separately been derived from phenomena. The disanalogy involved is thus that in the experimentum crucis (and its related sections in* The Opticks*) we use an argument for uniformity to establish a single causal claim, while Rule II licences the identification of similar causal parameters which were independently established and were deduced from phenomena by systematic dependencies.*

In the Principia *there are systematic dependencies, derived from the laws of motion, between causes and effects. Given the absence of systematic dependencies, Newton could offer only sufficient causes in* The Opticks*. Moreover, by means of what I call 'macro-micro inference tickets' (i.e. Props. LXX-LVI, Book I), Newton was able to license conclusions about the inverse-square centripetal forces of each of the individual micro-particles that constitute a macroscopic body from the overall inverse-square centripetal force exerted by that body –in this way, Newton was thus able to back up transductive inferences about the particles constituting a macroscopic body. In* The Opticks *none of the above was at hand. Newton clearly wanted to do more than to simply establish the phenomenological laws regulating optical phenomena: he also wanted to provide a solid physical account of optical phenomena. However, given the empirical and methodological problems Newton later encountered when methodizing optics in a Principia-style, it turned out that establishing non-hypothetical physical interpretations of optical phenomena was quite a difficult matter.*

It is the aim of this talk to pinpoint the dynamics between method and 'phenomena' in Newton's optical research.

Introduction

My basic premise is that Newton was somehow dissatisfied with his own optical work. Here I shall not further persuade you of the adequacy of this particular premise, as its case has, in my opinion, been made quite successfully elsewhere. In this talk I seek *to explain* why Newton was less successful to accommodate optical phenomena *according to his own methodological desiderata* of deducing causes from phenomena. In order to do so, I shall be contrasting Newton's methodology in the *Principia* with the method by which theoretical and causal conclusions were established in *The Opticks*. *Ab initio*, I wish to emphasize that, when I occasionally use the word "failure," I refer to Newton's inability to accommodate optical phenomena according to his *own* methodological ideals –so nowhere, do I use the word in a derogative sense.

As I shall argue in what follows, *the difference between* The Opticks *and the* Principia *does not lie, respectively, in the absence or presence of causal explanations, but in the different ways in which theoretical and causal statements were established*.

I shall focus on how Newton drew theoretical conclusions from the *experimentum crucis* and contrast this with how he concluded that inverse-square centripetal forces were causing the Keplerian motion of the primary and secondary planets. For presentational reasons, I have decided to focus on the *experimentum crucis*, which is *a symptomatic case* of Newton's "failure" in optics.

Newton's Argument for the Heterogeneity of White Light

Here I shall not dwell on the set-up of the *experimentum crucis*, which is, I suppose, rather well-known. I shall only discuss the conclusions which Newton drew from his *experimentum crucis* and investigate whether these conclusions can be justified by Newton's own methodological desiderata.

Newton's new theory of light and colours contained basically two claims: *one the one hand*, it encompassed the claim that there is a one-on-one correspondence between refrangibility and colour; *on the other hand*, it contained the claim that white light *consists* of a heterogeneous mixture of different colours. The former claim, *i.e. the claim on the one-on-one correspondence*, was based on observation which had shown that the rays emerging from prism *ABC* at the greatest angle of refraction are equally re-refracted by prism *abc*; similarly, rays emerging at the least angle of refraction are equally re-refracted by the second prism. And so on, for all intermediate rays of the spectrum. The latter claim, *i.e. the claim on the heterogeneity of white light*, entails that the colours, which are originally contained in white light before refraction, become visible when separated by a prism. According to Newton, prismatic colours are thus *not created* but *rendered visible by separation*.

Now, given the experiments he had performed, Newton could indeed understandingly claim that to every colour there corresponds a specific degree of refrangibility. However, his claim was based on experiments in two different refracting media only: glass and water, which seems to testify of Newton's belief in the uniformity of nature. Nowadays, we know that there are media in which red colours are more refracted than violet ones (e.g. in dye fuchsine or in iodine), and that the refrangibility of a ray can be modified (e.g. in the Doppler-effect). Nevertheless, given the media which Newton had studied, his claim on the one-on-one correspondence between colour and refrangibility was based on experiments –albeit on a limited range of experiments.

But what about Newton's generalization that white light *consists* of a heterogeneous mixture of different colours? Unfortunately, in his first optical paper, Newton did not dwell much on the specifics of how this generalization follows from the *experimentum crucis*. We do know that Newton was quite convinced of the correctness of his conclusion on the heterogeneity of white light. In a letter to Henry Oldenburg on 6 February 1671/2, Newton pointed out the following: "For what I shall tell concerning them is not a Hypothesis but most rigid consequence, not conjectured by barely inferring 'tis thus because not otherwise or because it satisfies all phænomena (the Philosophers universall Topick,) but evinced by ye mediation of experiments concluding directly & without any suspicion of doubt."[1] In view of several criticisms on his first optical paper, Newton never denounced his thesis on the heterogeneity of light. In response to Huygens' criticism, Newton did, however, restrict the *scope* of the theory. Whereas in the original paper he had made claims on the innateness of white light in general, in a letter to Oldenburg on 23 June 1673 he now restricted his theory to the innateness of the sun's light.

Much later, in a comment on Experiment 9 of Part I of Book I of *The Opticks*, which remained identical in all editions, Newton made the accompanying supposition more explicit:

---

[1] Newton, *Correspondence*, I, pp. 96-97.

> And that all such reflected Light is of the same Nature with the Sun's Light before its Incidence on the Base of the Prism, no Man ever doubted; it being generally allowed, that Light by such Reflections suffers no Alteration in its Modifications and Properties. […], So then, the Sun's incident Light being of the same Temper and Constitution with his emergent Light, and the last being compounded of Rays differently refrangible, the first must be in like manner compounded.[2]

Note that, if we do not accept that white light consists of rays differently refrangible, then we have to assume that a different refraction process occurred at the first prism than at the second prism of Newton's *experimentum crucis*: one for the *creation* of colours and one for the *common refraction* of colours. On this assumption, the rays where created at the first prism, while at the second prism the created rays were refracted. If we suppose, on the other hand, that white light consists of rays differently refrangible, then the effects in both prisms can be explained by the same refraction process. So it seems that causal parsimony and the belief in the uniformity of nature are what motivated Newton's endorsement of the view that white light consists of a heterogeneous mixture of colours. Unfortunately, the problem is that observing coloured rays in white light is impossible –for coloured rays become visible only after refraction. My point is that *Newton's claim that white light is a heterogeneous mixture of colours is utterly dependent on this specific argument of causal parsimony*.

At this point, one may point out that Newton might have relied on the Rules I or II of his *regulae philosophandi*, as Alan E. Shapiro has suggested in his *Fits, Passions, and Paroxysms*. Newton's first *regula philosophandi*, as formulated in the third edition of the *Principia*, states that: "No more causes of natural things should be admitted than are both true and sufficient to explain their phenomena [*quam quae verae sint & earum phenomenis explicandis sufficiant*]." The second *regula philosophandi*, which is in fact a corollary to the first, states, as formulated in the same edition, that "Therefore, the causes assigned to natural effects of the same kind must be, so far as possible [*quatenus fieri potest*], the same."[3] At first glance, reference to the *regulae* seems to be a reasonable suggestion.

However, this move will not do. Rules I and II might on a *prima facie* basis seem to express the idea of causal parsimony, to wit: the number of causes in natural philosophy should not be inflated beyond necessity, because nature operates economically. Upon closer consideration, in Rules I and II Newton also provides two desiderata that a proper cause in natural philosophy should meet: a cause should not merely be explanatory, it should also be true. Put differently, a true cause should not merely explain its effect; it should also be shown that its observable effect *necessarily follows* from this very cause. Once this is established, then, when its corresponding effect is observed, the cause can be safely inferred to exist. The question, then, that Newton is trying to answer in Section 2 of Book I of the *Principia*, is not so much *Which forces entail Keplerian motion?*, but rather *What are, given the laws of motion, the necessary and sufficient conditions for Keplerian motion?* Establishing that inverse-square centripetal forces are the necessary and sufficient conditions for Keplerian motion warrants that, *given the laws of motion*, Keplerian motion, in general, is produced by inverse-square centripetal forces, and inverse-square centripetal forces alone. On this reading, Rules I and II assert that causes shown to be necessary and sufficient of their effects *–and only such causes!–* are to be kept minimal. Rules I and II license the identification of instances of causes of the same kind which have been shown to be necessary and sufficient to explain phenomena of the same kind. In other words, in the context of the *Principia*, this implied that, once we have deduced from phenomena that the motions of Jupiter and Saturn are both produced by an inverse-square centripetal force, we may assume that these phenomena are produced by the same force: gravity.

On the basis of Rules I and II, we thus identify two or more instances of causes of the same kind, which have been derived separately from phenomena. *The disanalogy involved*, which is visualised on the screen, *is thus that in the* experimentum crucis *we use an argument of causal parsimony to establish a (single) causal claim, while Rules I and II in fact licence the identification of similar causes which were separately deduced from similar phenomena by means of the systematic dependencies established in Book I of the* Principia.

What I see Newton doing in his comments on Experiment 9, Part 1 of Book I of *The Opticks* is showing –at least on an implicit level– that the innateness of white light cannot be directly deduced from phenomena and that the strongest argument adducible for its establishment is his argument from causal parsimony which we have just spelled out. As I have also argued, this argument could not be licensed by *regulae philosophandi* I and II.

Looking with Unseeing Eyes into the Invisible Realm: The Problem of Transduction

Transduction refers to the reasoning process whereby inferences are made about the *microscopic components* of bodies from the observed laws and properties of the *macroscopic bodies*, which these microscopic components constitute (or are supposed to constitute).

---

[2] Newton, *The Opticks*, pp. 55-56.

[3] Newton, *The Principia*, pp. 794-795.

Newton, however, who insisted in the General Scholium (1713) that scientific propositions should be based on phenomena directly or on deductions from phenomena (for "whatever is not deduced from the phenomena must be called a hypothesis"), *could not*, as I shall explain in what follows, *infer statements about the invisible realm of optical phenomena in the demonstrative part of optics without introducing hypotheses*.

In the context of transduction, the "Analogy of Nature" was a guiding principle in Newton's research, for without the uniformity between microscopic and macroscopic components, it would be impossible ... "to derive the qualities of imperceptible bodies from the qualities of perceptible ones," as Newton observed in manuscript material on Hypothesis III (which would later become Rule III) in 1692. While the "Analogy of Nature" suggested to Newton that the micro-constituents of optical phenomena are similar or analogical to the bodies that fall within the reach of our observation, these micro-constituents are in themselves unobservable and, moreover, there is no way to justify the "Analogy of Nature" in this particular context. Therefore any characterization of them in corpuscular terms would remain utterly speculative. In different manuscript material, which was composed in the same period as Hypothesis III, Newton stressed that:

> Here only sensible [bodies] and their parts are treated [and it is] therefore that the argument of induction may have [its] place in them only. Distant [bodies] that cannot be perceived, but which are nevertheless hypothetically called bodies by some, should be more adequately treated in hypothetical Metaphysics and Philosophy.[4]

The tension between this quote and the previous quote from Hypothesis III, could hardly have escaped his attention. When Newton increasingly began to emphasize "Deductions from Phenomena" shortly after 1700, this tension became all the more stronger. Notwithstanding, in his optical research Newton *made* claims on the micro-constituents of optical phenomena (for instance, in his explanation of coloured bodies in Book II, Part III or in his hierarchical account on the structure of matter at the end of Proposition VIII, Part III, Book II of *The Opticks*).

Transduction in the *Principia*

Up to this point, I have discussed some of the problems surrounding Newton's optical research, however, I should also add some short observations on how transduction could be legitimately carried out in the *Principia*. On the basis of the propositions on the attraction of spherical bodies, i.e. Propositions LXXI-LXXVI (71-76) of Book I of the *Principia*, Newton could argue that the overall inverse-square centripetal force of a sphere on an external particle (or sphere) results from the summation of the individual inverse-square centripetal forces of each of the particles composing that sphere. In this case, transduction is rather unproblematic because the constituents of bodies share the same theoretically relevant property with the bodies they constitute: namely, mass. Allow me to elaborate this point. Newton clearly conceived of mass as an additive property: a body's (total) mass consists of the masses of its parts and it increases (or diminishes) as the number of parts increases (or diminishes). Since the gravity towards all planets is proportional to their mass, it follows that their gravity is also additive: the gravity of the whole results from the gravity of its parts. Given this subtle process of decomposition, Newton could bridge the gap between the micro- and the macro-level in the *Principia*. In optics, by contrast, transduction is problematic because it amounts to endorsing a particular hypothesis on the nature of light.

To avoid giving the impression that transduction was always unproblematic in the *Principia*, I should also point out in Section VII of Book II of the *Principia* Newton's attempt at transducing the micro-constituents of the inertial component of fluid resistance failed. Given the time-constraints, I will not further discuss this.

The Asymmetry between the *Principia* and *The Opticks*

Optical phenomena did not easily lend themselves to a *Principia*-style physico-mathematical treatment. As Newton experienced for instance in his study of diffraction, optical phenomena can behave in odd ways –rendering their study and characterization particularly resilient. In mechanics, the affected entities, i.e. the *explananda*: *bodies* moving along specific trajectories, and their constituting elements, i.e. the *particles* constituting these very bodies, all have a theoretically salient property in common: *mass*. In optics, by contrast, we do not know –at least not without speculating on the matter– the constituting elements of the *explananda*.

In order to get a grasp on the difference between *The Opticks* and the *Principia*, let us take a closer look at the axioms of *The Opticks*, which remained unchanged in all editions. The eight axioms in *The Opticks* basically deal with the geometrical properties of reflected and refracted light. Here I shall, however, not discuss all of these axioms. Rather, I shall provide some examples, which are required to make my next point. The first axiom states that the "*Angles of Reflection and Refraction, lie in the same Plane with the Angle of Incidence*;" the second axiom states that the angle of reflection is equal to

---

[4] My translation of CUL Add. Ms. 3965, f. 422^{r}.

the angle of incidence; the third axiom states that if a refracted ray is returned to the point of incidence it will be refracted into the initial line by the incident ray; the fifth axiom contains the sine law of refraction which holds "either accurately or very nearly."

In contrast to the laws of motion in the Principia*, the axioms in* The Opticks *characterize phenomenological relations described in geometrical terms and they do not carry information about the proximate causes producing these phenomena*. The laws of motion served as a theoretical toolbox that allows one to gather information about the forces acting upon bodies. By Law I, Newton could infer the presence of a centripetal force from non-inertial motion; by Law II, he could establish the magnitude and direction of a centripetal force producing such non-inertial motion; and, by Law III, he was able to relate the centripetal force to its counteracting reaction force.

Another way of putting it is that *The Opticks* could not transcend the tradition of the *scientiae mixtae* and of geometrical optics more particularly *–at least not without considerable abductive and inductive risk*. In contrast to the physico-mathematical theory of the *Principia*, which provides causal explanations of the *explananda* from "within" the theory, a mixed-science treatment describes a given phenomenon mathematically, without an accompanying explanatory story. This contrast is again visualized on the screen. Newton, however, wanted to do more than to simply establish the phenomenological laws regulating optical phenomena: he also wanted to provide a solid physical account of optical phenomena. In order to be explanatory, a mixed-science treatment requires the addition of a causal story, which by definition falls outside of the mathematical description.

In the Principia*, which stood in the tradition of physico-mathematics, such causal stories could be licensed by the systematic dependencies between cause and effect, which were derived from the laws of motion. In other words, the proximate causes to be adduced in Book III of the* Principia *are constrained by the laws of motion*. As a way of reducing the risk of wild speculation, Newton demanded that the causes of orbital motion ought to be derivable from the laws of motion, i.e. from principles that have already shown their usefulness in natural-philosophical inquiry. In other words, to avoid introducing arbitrary causes into natural philosophy, Newton required that causes should be derivable from non-arbitrary principles or laws. The motivation behind this was to get rid of the problem of causal under-determination which vexed the method of hypothesis, to which Newton referred to in a letter on 10 June 1672 to Henry Oldenburg for Ignace Pardies: "For if the possibility of hypotheses is to be to test the truth and reality of things, I see not how certainty can be obtained in any science; since numerous hypotheses may be devised, which shall seem to overcome new difficulties."[5]

Newton's derivation of causes in the *Principia* contrasts significantly with his explanation of the *experimentum crucis*, viz. that white light consists of rays differently refrangible. This claim was established by an external consideration, i.e. a consideration independent of the mathematical *exposé* of the reported refraction patterns: Newton's argument of causal parsimony which we have spelled out previously. Given the absence of systematic dependencies, Newton could only offer *sufficient causes* in *The Opticks*. In a letter to Newton on 13 October 1676, Anthony Lucas, one of Newton's most acute commentators, pointed out that the heterogeneity of white light is only a sufficient cause of the effects described in the *experimentum crucis*. According to Lucas, Newton did not prove "*that this unequall refraction necessarily implyes an unequall refrangibility in rays differently coloured*," therefore "not evinceing that this inequality ariseth from an unequall *refrangibility*, *intrinsecall* to *rays differently coloured*." More generally, given the empirical and methodological problems which Newton encountered while trying to methodize optics in a *Principia*-style manner, he found out that establishing non-hypothetical causal interpretations of optical phenomena was quite a difficult matter. As I have documented in the preceding sections, Newton's ideal of deducing causes by their effects turned out to be unattainable in optics: 1. *the fundamental principles in optics remained uncertain*, 2. *no methodological justification for the use of transduction within the realm of optics could be provided*, and 3. *the causal claims introduced in* The Opticks *could not be constrained by theory*.

In *The Opticks* Newton occasionally transcended the strictly observational features of optical phenomena and this did not exactly fit hand in glove with his methodological standards. Therefore Newton's "failure" in *The Opticks* was his failure to meet the very standards he had formulated himself. In *The Opticks*, therefore, Newton was genuinely facing the limits of deducing from phenomena.

THE STETHOSCOPE. HOW THE PRESENTATION OF A MEDICAL INNOVATION INFLUENCED ITS SUCCESS

Maria WINTER
Institute of the History, Philosophy and Ethics of Medicine, Universität Ulm, GERMANY
maria.winter@gmx.net

Abstract

Laennec's De l'Auscultation Médiate *(1819) has been criticized even by its translator, John Forbes, for being "written in a diffuse and verbose style by no means commendable in a work of science". The modern reader would wholeheartedly agree, especially since the book also seems to indiscriminately mingle case reports, pathogeneses, diagnostics, post-mortem analyses, physiology and numerous other elements including anecdotes from the author's life. Only a very small proportion is dedicated to the stethoscope and its use.*
It is interesting to observe that in fact Laennec's contemporaries perceived the work above all as a treatise on anatomical pathology and not so much as a handbook for a new means of diagnosis.
For his first English translation, Forbes consequently rearranged and considerably shortened the book, "restoring" it to "what I humbly conceive it ought always to have been".
The most common criticism was, however, the sheer length of the work; two volumes of 470 and 472 pages. Soon concise versions, even tiny "pocket versions" and overviews in tabular form, came out. Their great variety seems to suggest a considerable demand.
But not all objections were based on presentation. The new method of diagnosis was criticized "because its whole hue and character is foreign, and opposed to all our habits and associations." It was considered too complicated to learn, too mechanical and against the old art of Hippocratical medicine. But this all didn't stop the stethoscope from becoming inevitable within only a few decades.
On the basis of books, press and journal reports, the paper seeks to examine how far the way of presentation chosen by Laennec served as inhibitor or promoter to the international success of his invention, with special focus on France, Britain and Germany.

In 1819 a book was published which was meant to change the world of medical diagnostics forever. Its title was *De l'auscultation médiate ou traité du diagnostic des maladies des poumons et du coeur, fondé principalement sur ce nouveau moyen d'exploration*. (On mediate auscultation, or treatise on the diagnostics of illnesses of the lungs and heart, mainly based on this new means of exploration.) By "this new means of exploration", of course the stethoscope or 'cylinder' was meant, an invention made by the author, René Théophile Hyacinthe Laennec, in 1816.

The work contained two volumes of 456 and 472 pages –plus tables– and at first sight seems equally disappointing and confusing to the modern reader. Only a small proportion is dedicated to the stethoscope and its use, the rest indiscriminately mingles case reports, pathogeneses, diagnostics, post-mortem analyses, physiology and numerous other elements including anecdotes from the author's life.

In this paper, I will examine how this form of presentation influenced the success of the medical innovation presented in these two volumes, the stethoscope.

Even though the history of the stethoscope and the life of Laennec are among the better researched topics in Medical history, with several excellent monographs and countless articles under numerous different approaches and focuses,[1] this particular aspect seems to have received very little attention so far. This is quite surprising, since the form of presentation was a major concern of contemporary reviewers –and to them clearly presented an obstacle to the success of the stethoscope and the technique associated with it, mediate auscultation.

This paper is mainly based on reviews of Laennec's work in the corpus of contemporary books and journals from France, Germany and the UK that is available online and also on the reviews mentioned in Patrick James Bishop's extremely useful –though not always accurate– bibliography of Laennec, which he assembled during decades of research.[2]

The Status quo ante

Before the invention of the stethoscope, medical diagnosis was principally based upon the patient's own narrative, combined with some very few methods of physical examination like palpation or pulse-taking.

Percussion –diagnosis by tapping on the patient's body– an invention that the Viennese physician Leopold Auenbrugger published in his *Inventum novum* in 1761 had become out of use in Germany and was little known in England. In France, however, the situation was different since the translation of Auenbrugger's *Inventum novum* by Jean-Nicolas Corvisart, the primary physician of Napoléon Bonaparte, in 1808[3] and it seems that percussion was also used to some extent in Edinburgh.[4]

The Stethoscope and mediate auscultation

The stethoscope has experienced a considerable evolution from the first trial model made of cardboard over the first professional versions made entirely of wood to the modern, binaural stethoscope we all know. Even though other means of diagnostics have become far more important, it still is a symbol of the medical profession and it already was as early as the mid 19th century.

The diagnostic technique involved in the use of the stethoscope is called "mediate auscultation", from Latin *auscultare* –to hear with attention, listen to, give ear to. **Immediate** auscultation, with the ear directly applied to the patient's body, had already been used by Hippocrates. Laennec's innovation therefore consisted in adding a wooden cylinder as intermediary –as he claimed to improve the aural effect, but also for modesty reasons when examining female patients– and a classification system for the sounds obtained.

The main fields of criticism

The book has missed its topic

Verl., 1997); Jacalyn Duffin, *To see with a better eye: A life of R.T.H. Laennec* (Princeton, New Jersey: Princeton University Press, 1998). and several other works by these two authors.

2 Patrick James Bishop, *A bibliography of R.T.H. Laennec (1781-1826): An attempt to list all publications by or about him, together with a list of manuscripts, letters and other related material* (Sydney NSW: Royal Australian College of Physicians, 1981).

3 Wutzer, 'Ueber das vom Herrn Dr. Laennec in Paris neuerdings bekannte gemachte Verfahren zur Exploration des Zustandes der Brustorgane, nebst einer Analyse des von ihm über denselben Gegenstand herausgegebenen Werkes', *Journal der Chirurgie und Augenheilkunde*, 1820, 359–79, 359–60; Saul Jarcho, 'A Review of John Forbes' Translation of Laennec', *Am J Cardiol*, 10 (1962), 859–63, 863.

4 Malcolm Nicolson, 'The introduction of percussion and stethoscopy to early nineteenth-century Edinburgh', in William Frederick Bynum and Roy Porter (eds.), *Medicine and the five senses. Based on a Symposium on Medicine and the Five Senses, held at the Wellcome Institute for the History of Medicine on 11-12 June 1987* (1. paperback ed., Cambridge: Cambridge University Press, 2004), 134–53.

By quite a few of Laennec's contemporaries, the treatise was seen as a work of pathological anatomy or on chest diseases:

> Le livre que nous avons à faire connoître, étant formé presque en entier des descriptions de maladies et de faits anatomiques (…) [qui] peuvent intéresser les médecins, et sur-tout les élèves, parce qu'ils y trouveront les effets liés avec les symptômes qui devoient les présager, si l'on en excepte des anomalies impossibles à soupçonner. (…) l'auscultation médiate, que M. Laennec appelle l'objet principal de son livre, et que nous regardons comme l'accessoire, eu égard à la totalité de l'ouvrage, qui est un bon traité des maladies de la poitrine.[5]

I only found one isolated author, Italo-English physician August Bozzi Granville, who in his 1820 review thought that Laennec had used pathological anatomy as mere "accessories" to the description of mediate auscultation, since the book was aimed at introducing mediate auscultation into the praxis of medical diagnosis. However, Granville found the parts of the book dealing with pathological anatomy "very important".[6] [7]

The book is too long

The sheer length of Laennec's treatise was commonly criticised, even in France, and it was seen as a great obstacle to its practical use.

> L'ouvrage de M. Laennec est un livre éminemment pratique; mais nous avons craint que son étendre ne fut un grand obstacle à son utilité.[8]

One French reviewer was convinced that Laennec would have abridged the post mortem reports, if only he had had the time:

> Il eût peut-être possible à M. Laennec de donner moins de longueur à son ouvrage, en abrégeant un peu des descriptions d'ouvertures de corps, sans omettre les lésions importantes. Il l'aurait fait, sans doute, si d'autres occupations le lui eussent permis.[9]

Among those who criticised the length was Laennec's personal enemy, François Broussais (1772-1838), like Laennec also a former pupil of Corvisart, but follower of a different medical school. Laennec commented on this in the preface to his second edition: "I never thought that one should learn everything by heart."

> Je n'ai jamais pensé qu'on dût les apprendre par cœur.[10]

Even though Laennec himself did not find it necessary, the medical profession soon developed its coping strategies. Countless condensed versions appeared within the first decade of the first publication of Laennec's treatise, most of them in medical journals, sometimes as a whole series, for example in *The Lancet* in England and the *Medicinisch-chirurgische Zeitung* in Germany.

Some of them clearly stated that the purpose of their summary was to free the busy practitioner from the lengthy lecture of the original, allowing him to form an opinion or even serving as a practical manual.

> Nous avons (…) cru rendre un véritable service aux gens de l'art, aux praticiens surtout, qui n'ont pas le temps de s'adonner à des longues lectures, en leur donnant une analyse de cet ouvrage suffisamment détalillée pour qu'ell puisse leur tenir lieu de l'ouvrage lui-même, et assez succincte pour qu'elle puisse leur servir de manuel pratique. > L'ouvrage de M. Laennec est long, trop long peut-être; et les praticiens occupés n'ayant pas le temps de lire un livre de si longue haleine, voulant néanmoins profiter des signes nouveau au moyens desquels ils pourront mieux apprécier les diverses altérations thoraciques, trouveront sans doute avec plaisir dans quelques pages l'extrait de tous ces signes. Bien q'un peu aride, un pareils travail sera lu par l'attrait de la nouveauté du sujet, l'éspoir d'en retirer un grand avantage et de pouvoir le juger soi-même. Tel sera le but de cet article, qui ne sera mêlé d'aucunes réflexions critiques.[12]

Auscultation manuals appeared, like William Stokes' "Introduction to the use of the Stethoscope" in 1825 or Adam Raciborski's (1809–1871) "New and complete manual of auscultation and percussion" in 1835. Raciborski's work appeared almost simultaneously in French, English and German and was especially popular in France.[13]

The most extreme examples of abridged versions are probably Richard Townsend's "Tabular View of the Prinicipal Signs Furnished by Auscultation and Percussion" from 1832 and the "Laennec in der Westentasche" (Waistcoat-Pocket-Laennec) which enjoyed at least 3 editions in the 1860s and 1870s.

The structure of the text

The translator of the English version of Laennec's treatise –which came out as early as 1821– , John Forbes, both rearranged and considerably shortened the book, restoring it to "what I humbly conceive it ought always to have been". He was convinced that both the English reader and the original author should be thankful for this.

Forbes had in fact created two separate works and divided pathology from diagnosis.

Reviews of Forbes' translation generally welcomed this rearrangement and saw it as an important improvement compared to the original,[14] but not all agreed with the considerable abbreviation of the case reports[15] –usually condensing several pages into just a few lines.

> Dr. Forbes is entitled to much praise for the laborious task he has imposed on himself of re-modelling the arrangement of the original work, and concentrating the language, so as to occupy but one volume instead of two - a double improvement, that saves both time and expense. He has also enriched the work by the addition of a sensible preface, and many valuable notes.[16]

> We consider the translator's arrangement as a considerable improvement, and as tending in a most essential manner to facilitate the reference of the Practitioner.[17]

Forbes himself had second thoughts on this and included longer case reports in the second, 1827 edition of his translation and he also published a separate volume of "Original Cases with dissections and observations illustrating the use of the stethoscope and percussion in the diagnosis of diseases of the chest" in 1824.

Part of the somewhat confuse structure of the original French edition might be due to the fact that Laennec had agreed to 'deliver' his work to the publisher bit by bit, the last part no later than June 30th, 1819.[18]

Some French critics, on the other hand, praised the order observed by Laennec in his work as "corresponding to the true principles of analysis":

> L'ordre suivi par M. Laennec dans la rédaction de son ouvrage est conforme aux vrais principes de l'analyse, puisqu'il commence par donner l'état anatomique positif des maladies dont il veut recueillir les signes par l'auscultation immédiate (sic!), et qu'il appuie ensuite par des fait ce qu'il a dit précédemment.[19]

For his second edition, which appeared in 1826, Laennec considerably changed the structure and apparently also picked up some of Forbes' alterations, separating pathology more clearly from diagnosis. Even though Laennec did not speak any English –or, in fact, any other modern languages besides French and Breton–, we know that he was aware of Forbes' edition and that the two actually exchanged letters.

As you would expect, the alterations in the second French edition were warmly welcomed in England, it was said to be "so much more distinct and systematic, that its value is greatly increased".[20]

Language and Style

Laennec's writing style found very little sympathy in the English-speaking world. His translator John Forbes stated in his introduction to the second edition: "(…) my translation (…) will be more valuable than if it had been strictly literal; a good deal of the original being written in a diffuse and verbose style by no means commendable in a work of science."[21]

It seems his compatriots were pretty much in line with this judgment. On the literary character of Forbes' translation, one reviewer stated: "It appears, upon the whole, to be both perspicuous and succinct, and to possess but little of the French idiom. These are great requisites as the translation of a medical work, which is strictly descriptive, ought to aspire to." A certain lack of linguistic variation was diagnosed, but that was considered as beyond the translator's responsibility.[22]

The French strongly disagreed. Even in 1925, Laennec was still praised for his excellent style, which was "severe, condensed, clear, elegant –real medical writing" ("sévère, condensée, claire, élégante (…), véritable écriture médicale"[23]).

A French 1933 thesis stated that Laennec's elevatedness of thinking harmonizes with the grave, austere and meditative form. His language is compared to that of Pascal or Bossuet in its affluent power, its balanced rhythm and also what he calls *allure combative*:

> La hauteur de la pensée s'y harmonise à la forme grave, austère, méditative. (…) Cette langue de Laennec nous semble très proche de celle d'un Pascal et d'un Bossuet par la puissance aisée, l'équilibre des périodes, aussi par l'allure combative (…)[24]

Even Michel Foucault in his Birth of the Clinic (1963) praises "the extraordinary beauty" of Laennec's description of liver cirrhosis.[25]

So, just like nowadays there were considerable national differences in what was seen as an appropriate academic style.

Terminology

Laennec probably would have loved to have the multimedia possibilities of this mid-1990s educational software [the "Laennec CD-ROM"[26]] but this was of course not possible in the early 19th century. So he chose to describe auscultation sounds in metaphorical, sometimes rather poetic terms, in order to achieve a 'graphic' effect.

Of course these were not self-explanatory and it is –for instance– quite difficult to explain why something that sounds like "the cooing of a wood-pigeon" should be classified as "râle" (which means rattle or stertorous breathing)[27].

John Elliotson took his medical doctorate in 1821. He was very much drawn to auscultation but had to struggle to master it. As he told years later in a clinical lecture delivered at St. Thomas Hospital in London, he once heard what he took to be a "metallic tinkling" and a "click" and said he never could have imagined before what Laennec could possibly mean with those descriptions. So he undertook to learn right from the master himself in Paris, but Laennec was already too ill to teach.[28]

Gabriel Andral (1797-1876), who had incurred Laennec's anger for having experimented with auscultation without his authorisation, was the first to develop a new systematic of auscultation sounds in his 1821 Paris thesis on diseases of the chest.[29]

Peter Mere Latham (1789-1875) invented his own classification of auscultation sounds (mainly distinguishing dry from moist sounds for the lung) in his "Lectures on subjects connected with clinical medicine" in 1836.[30]

In 1839, Andral's pupil Jules Fournet (1812-1888) developed an extremely elaborated system of auscultation sounds, in a two-volume book based on his 1837 thesis. The classification was organised in different layers and resembled the taxonomy of the botanists of the Enlightenment period. Criteria were –amongst others– intensity and pitch of the different sounds.[31]

Also in 1839, Viennese physician Josef Skoda (1805-1881) developed yet another system of auscultation sounds. Just like Laennec, he also tried to match sound phenomena and anatomical alterations, but he did not suppose a simple 1 to 1 relation.[32] Skoda made a distinction between the 'chemical behaviour' of the organs, which lead to anatomical alterations and the 'mechanical behaviour' that produced auscultation sounds. Acoustic principles were the major guideline for the analysis of auscultation signs. If there was no physical explanation, the sign was to be considered as 'unreliable'.[33] Whereas Laennec had presented an abundance of clinical cases and postmortems, Skoda's book was based on theoretical reasoning and descriptions of acoustic experiments.[34] The quasi-visual depictions that Laennec used so frequently are quite absent in Skoda's work.[35]

So now the French school "which cultivated the senses" was facing a new, "rational" German one.[36]

As one could almost expect, Skoda's approach wasn't much of a success in France.[37]

In Germany, on the other hand, Laennec's signs were considered as too complicated around 1840 and Fournet's system as completely unusable.[38] Skoda had reduced the number of stethoscopic signs and was seen by many as the grand simplifier of the method. [39]

Skoda had a considerable success with his diagnostic, soon became head of department and in 1846 professor of medicine. Students of all ages and all nationalities began flocking to Vienna.[40]

With all the competing systems, it is no wonder that the correct classification and interpretation of auscultation sounds remained an issue of controversy well into the mid-nineteenth century.[41]

The written text cannot replace teaching

Learning to distinguish the different sound phenomena was generally considered a long and assiduous task,[42] taking more patience than most readers had.[43] Only part of the phenomena could be learnt through self-teaching,[44] an

apprenticeship in Parisian hospitals was generally considered more favourable –but this meant a disadvantage to non-French practitioners and students of medicine.[45]

But soon pupils of Laennec and other young physicians acquainted with the new technique offered both private and university courses in the use of the stethoscope, placing adverts in medical journals and the daily press.

Real life presentation: PR activities

Some reviewers noted with a certain enervation that Laennec left out no possibility for promoting himself and the stethoscope. He presented his invention wherever he could and wherever it seemed favourable to him,[47] be it the Academie Royale des Sciences de l'Institut de France[48] or the Societé de Medicine, where he even took a patient for demonstrations.[49]

François-Victor Mérat de Vaumartoise (1780-1851) was present at one of these events and even though the patient was clearly suffering from a very high degree of tuberculosis, he could not hear the *pectoriloquie* that was so evident according to Laennec –nor could other participants.

> Nous devons avouer que les essais que nous avons faits avec le pectoriloque ne sont point à l'avantage de cet instrument. Nous avons cherché à nous assurer de la pectoriloquie sur une malade que M. Laennec a présentée lui-même à la société de la faculté, comme pectoriloque, et qui était effectivement dans un degré très-avancé de phtisie : nous n'avons pu l'entendre; d'autres membres n'ont pas été plus heureux que nous[50]

Foreigners, who had visited Laennec in Paris and joined him during his hospital rounds, reported the same.[51]

Laennec was once again not amused and in his preface to the second edition of his treatise ranted about "deaf people" and that there was "nothing worse than those who do not want to hear".

> Il y a d'ailleurs des sourds, et, comme l'a remarqué un des auteurs du *Dictionnaire des Sciences médicales* (article *stéthoscope*), il n'y en a pas des pires que ceux qui ne veulent pas entendre.[52]

He also presented free copies to his treatise to institutions like the Académie des Sciences (27. November 1819)[53] or to Matthew Baillie (1761-1823), personal physician to George III and George IV, a specialist in morbid anatomy who also practised percussion.[54] Baillie's copy is preserved and was digitised by the Bibliothèque Nationale de France for their Gallica project.[55]

Conclusion

Even though the form of presentation in Laennec's "De l'Auscultation Médiate" was commonly seen as a big obstacle, it had relatively little influence on the success of the stethoscope and of mediate auscultation. The medical profession took enough interest in the new invention to come up with compensation strategies against its main weaknesses –be it length, structure, language and style, terminology or the need for practical teaching– and Laennec's promotional campaign and personal network –amongst others his several hundred foreign students– played a role that cannot be underestimated for the first years after the invention of the stethoscope. In the longer run, other factors played a more important role like the open-mindedness of the medical profession –in Scotland even medical professors attended auscultation classes– or the approach to medical teaching. Bedside teaching was common practice both in France and Scotland where the stethoscope found its way into everyday practice a lot earlier than in England and Germany, where medical teaching was almost exclusively academic and theoretical.

The success of a medical invention is a multi-factored process in which presentation is only one –and as it seems not always the most important– element.

Abstract

During the decade 1860-70, the French chemist Alphonse Poitevin (1819-1882) did research work on the photographic sensitizing properties of dichromated gelatin, which led to the development of several printing methods by photomechanical processes. This allowed significant advances in several scientific and technical fields such as cartography; production of printing maps was done with more precision and in an easier and economical way. The printing of maps by photomechanical processes led to remarkable changes in cartographic cameras, lenses and printing instruments produced by European makers.
The study of the chemical and physical principles of the most important photomechanical techniques used in the second half of the 19th century cartography will be presented, namely the three-colour photographic printing processes developed by Charles Eckstein in the Netherlands and José Julio Rodrigues (1843-1893) in Portugal. We also intend to relate their work with the photocollographic process (tricromy) developed in France by Louis Ducos du Hauron (1837-1920). In 1878, Ducos du Hauron presented at the Universal Exhibition of Paris his process of tricromy, but without obtaining any impression using photomechanical processes. At the same time Rodrigues researched and obtained coloured photomechanical prints. A parallel study of the optical, photographic and printing instruments specially designed for the 19th-century cartography will be done.

Introduction

In the first half of the 19th century the evolution on the technology of paper making, metallurgy and the invention of photography had a great impact on map production.

The first maps were printed in letterpress or relief printing. Engraving or intaglio printing on metal plates, usually on copper, was used for the period 16th-18th centuries. Both these printing processes were expensive and tedious to accomplish. After the invention of lithography around 1798, this was the main method used for map printing production[1]. Lithography was the most manageable and the reproduction of the maps was achieved by direct drawing or transfer on a heavy stone.

In a paper submitted to the Geographical Congress held in Paris in 1876, Captain James Waterhouse (1842-1922), Assistant Surveyor General of India stated:

> *"Among the many useful and important artistic and scientific applications of photography one of the most valuable is the reproduction by its means, in absolute facsimile, of maps and plans, speedily and cheaply and on any scale –either the same, larger or smaller (…) most of the civilized countries now possess special photographic studios for the reproduction of maps, plans, etc, (…) for fiscal, military and other purposes."*[2]

The experiment done by Joseph Nicéphore Nièpce (1765-1833) in 1826 on the light-sensitivity properties of bitumen of Judea with a heliographic engraving on a pewter plate provided a method of photomechanically reproducing line drawings on paper[3]. In 1852 Talbot invented what he called a "photoglyphic print"[4]. These two first experiments were later followed by several other methods of engraving using the photographic process[5]. The discovery of Mungo Ponton[6] (1801-1808) in 1839 of the light-sensitivity of silver chromates was the turning point in the development of the photomechanical processes. Alphonse Louis Poitevin (1819-1882) studied the behaviour of dichromated albumen exposed to light on a lithographic stone. With this method he won in 1867 the prize for photomechanical printing offered by the Duc de Luynes. He was also the inventor of the collotype, a practical photolithographic technique which used the controlled reticulation of exposed and heated gelatin on a glass plate.[7]

The photomechanical processes shared the following principle: a photosensitive substance applied to a hard surface (stone or metal), became insoluble after exposing it to light through a photographic negative. The parts protected from the light remained soluble and after washing it the support retained a positive impression of the image, ready to be inked and printed. As an alternative, a transparent positive image could be used on metal. In this case the areas under the dark part of the image disappeared and the metal was afterwards etched out with an acid solution and inked for printing. They were categorized in the same way as the taxonomy of print: relief, intaglio and planographic.

Photomechanical processes and the printing of maps

The attention of cartographers was directed to the new photomechanical methods. During the period 1850-1870 the photographic and photomechanical methods on map making were mainly used for the printing and reproduction of maps as well as reductions and enlargements of the map scaling. They had several advantages over the time-consuming tradicional processes: easier printing, the scale-variation achieved without having to employ the difficult and tedious process with the pantograph and the introduction of the half-tone printing[8]. This led to an increase in the use and diffusion of maps.

The first serious attempt using photography for the reduction of maps was done in 1855 by Colonel Henry James (1803-1877), Director of the Ordnance Survey of Great Britain and Ireland,[9] who proved in front of the English parliament that

[8] Half-tone was a photomechanical printing process that translated the tones and details of a photographic image into a printed pattern of tiny dots.

[9] According to Mumford in the early period of mapping by lithography and other processes, the principal output was for the military and not for sale. In Mumford, I. (1972), *Cartographic Journal*, vol. 9, pp. 30-35.

using these new processes, the reduction of a map could be obtained with better results than the traditional ones[10]. James together with J. W. Osborne (1828-1902) also invented photozincography, in 1859, a planographic printing from zinc plates "*by which impressions were produced in an analogous way to photolithography*"[11] (fig. 1).

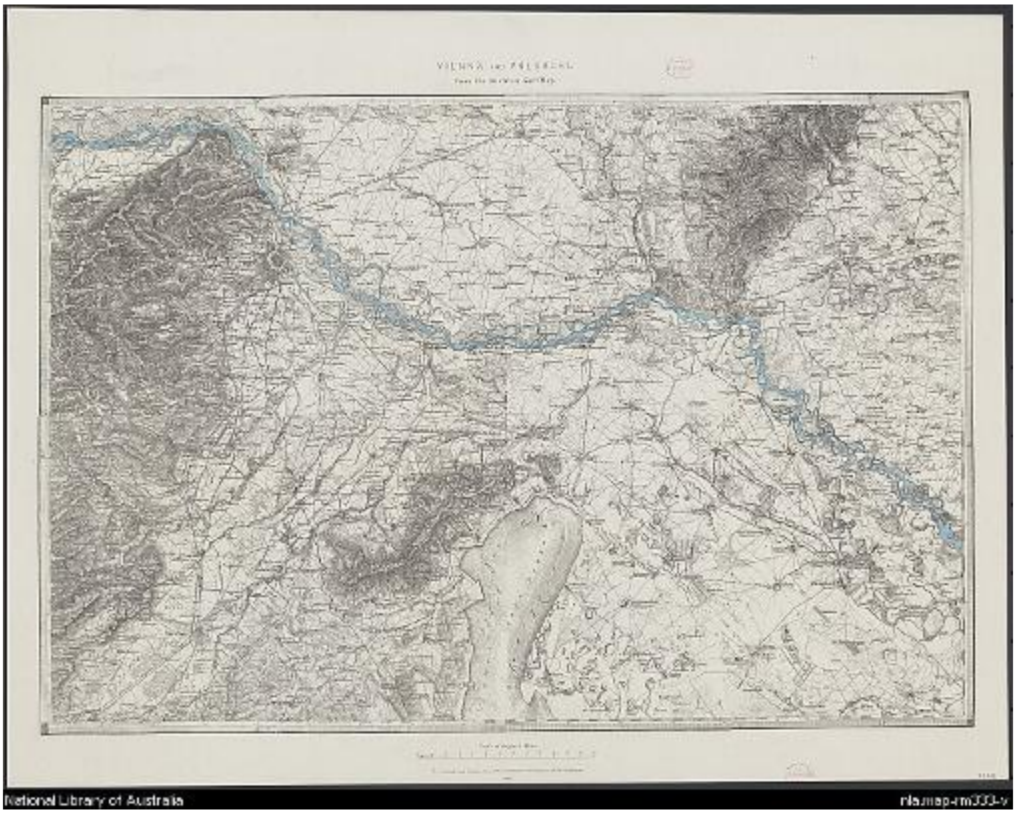

Fig. 1: Southampton: Photo-zincographed at the Ordnance Survey Office, Southampton, Col. Sir H. James, 1866.[12]

The Austrian-Hungarian Ordnance Survey was one of the first Geographical Institutes to adapt the new photomechanical methods for map reproduction. In the Universal Exhibition in Vienna (1873), "*an impressive collection of maps executed by heliogravure and photolithography was exhibited*"[13]. The Military Geographical Institute, founded in 1806 in Vienna, played an important role in the history of the graphic reproduction processes. This was mainly due to the work of Ottomar Volkmer (1839-1901), director of its photographic department and president of the Vienna Photographic Society and to his successor Baron Arthur Hübl[14] (1853-1932), a remarkable researcher on colour photographic processes.

The first cartographical cameras were installed in the Geographical Institutes throughout Europe around the 1860s. The main qualities demanded of these cameras were that they should be equipped with distortion-free lens and that parallel planes of copy and negative should be achieved[15]. However progress was slow due to the imperfection of the images obtained, derived mainly from the poor quality lenses available at the time. In 1859 John Henry Dallmeyer (1830-1883) formed his own company producing very high quality optical and photographic instruments[16]. By 1861 he had designed the

triple-achromatic lens, an arrangement of three achromatic doublets. The Rapid Rectilinear lens, or RR lens, was introduced by Dallmeyer in 1866 and as Dallmeyer wrote[17], "*For copying purposes the rapid rectilinear is without a rival. It has already been supplied to all the government topographical establishments in Europe, India and Australia"* (fig. 2).

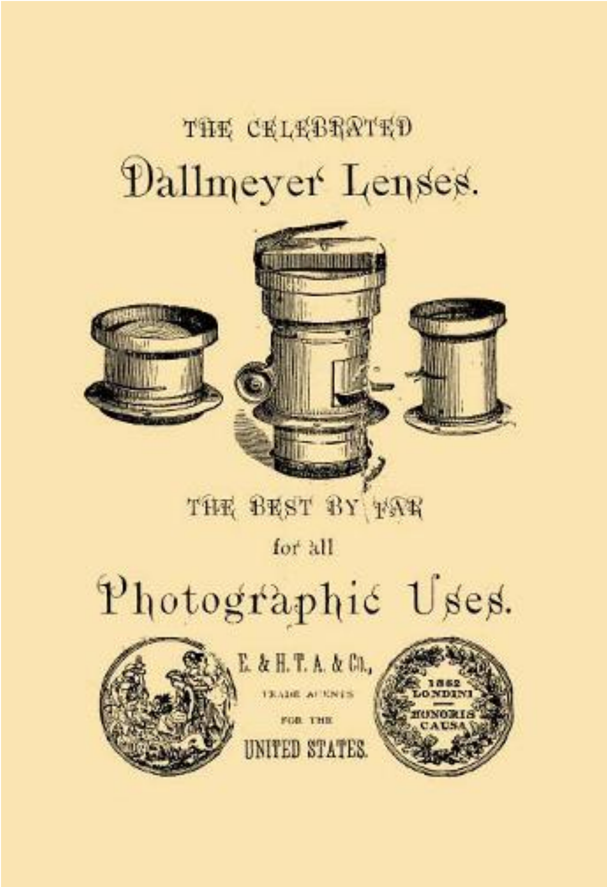

Fig. 2: Dallmeyer's cover book on photographic lenses.

Around the same time Hugo Adolphe Steinheil (1832-1893) invented a similar design to the RR lens, the aplanat, most probably due to his friendly relation with the Munich mathematician Phillips Von Seidel (1821-1896) who established at the time the theory of lens aberration (Seidel sums)[18]. Both lenses were constructed under the same principle, with a pair of achromatic lens element groups, arranged symmetrically before and behind the diaphragm. They were made of flint glass with an aperture of f/8. This lens construction reduced radial distortion[19] (figs. 3 and 4).

The camera was usually fixed on a stand, it could be moved along rails so that the distance of the camera from the plan-board where the map to be reproduced was, would be adjusted according to the scale required. With such a camera, a master copy of the map was duplicated, providing also the possibility of enlargements or reductions of certain parts of the map (fig. 5).

In the 1860s there were still some problems concerning the map printing processes to be solved[20]: adequate lighting (around 1860 when the camera was starting to be used for the cartographic work, electric lighting was an exception), substitution of heavy stones by a lightweight and cheap printing surface and better polychromatic printing. Some of the problems were, to some extent, partially solved the following years by several Surveys and geographical Institutes in Europe. The Portuguese Geographical Institute and the Dutch topographical Department at The Hague played an important role in this historical evolution in map printing during this period.

A case study: the Photographic Section of the Portuguese Geographical Institute and the colour printing of maps

In 1872 under the directorship of general Filipe Folque (1800-1874) the Photographic Department for cartographic reproduction is created in Portugal. Jose Julio Rodrigues (1843-1893), a professor of chemistry at the Lisbon Polytechnic School, is appointed its Director (1872-1879). The main photographic processes practiced there were the wet and dry collodion on glass (negative and positive) and the albumen silver print. Dichromated gelatin and bitumen of Judea were employed in several photomechanical processes such as photolithography, photogravure and typogravure using different supports (stone, copper and zinc). Rodrigues introduced a new material for his technique of photolithography: a thin piece of tinfoil was coated with an ammonia dichromated gelatin. This was put under the negative, and altering exposure to light it would give a photographic image. Greasy ink was then applied to the wet surface for a lithographic print. He considered this

[21] Hannot, A. (1881), *Communications de l'Institut Cartographique Militaire. N°17. Notice sur les travaux de la reproduction de la carte de Belgique au 20 000e et au 40 000e*., Bruxelles, A. Cnophs fils, p.34.

method the best for producing photolithographed maps as tin plates were inextensible and impermeable. In 1874, a communication about this process was sent to the *Société Française de Photographie* and was presented by Louis-Alphonse Davanne (1824-1912) at a meeting of the Society held on the 5th of June of that year; it was published in the society's bulletin[22]. Another important innovation done as early as 1878 by Rodrigues was the typo-autographic method for the lettering on maps: moveable types were printed on special paper which was cut out and pasted on to maps and reduced photographically[23] (fig. 6).

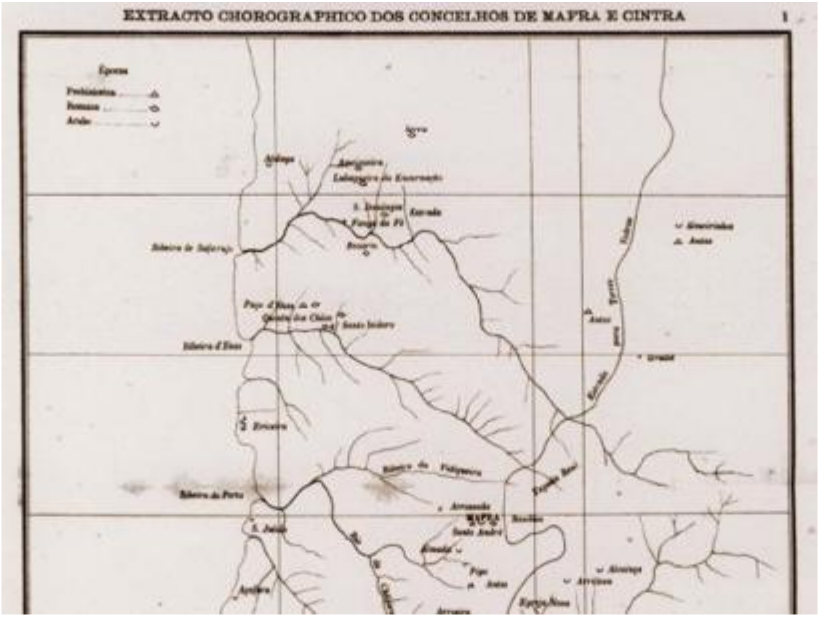

Fig. 6: Detail of *"Extracto Chorografico dos Concelhos de Mafra e Sintra"* done by the typoautographic process (IGP archive, c.a. 1878).

In the Portuguese Geographical Institute a big Dallmeyer camera with a focal distance of more than 3m was in use, allowing to obtain photographic reproductions of 75cm square, with either the triplet or the rapid rectilinear from Dallmeyer. With a second smaller Dallmeyer camera, photographs of 44cm square were obtained with a triplet objective. A Steinheil prism was also used for taking negatives for collotype printing. By placing a reverse prism in front of the lens, the image passed through the lens reversed and was impressed directly on the sensitive plate[24]. Usually these cameras were under a shelter receiving natural illumination. In very few cases, such as in the Portuguese Geographical Institute, artificial light was used. In this case electricity was produced by a magneto-electric Gramme machine[25]. This was probably the first establishment of its kind to use electricity for this purpose. Examples of printed maps from the Photographic Department are presented in fig. 7 and fig. 8.

Among other printing instruments the Photographic Department had a lithographic press constructed by H. Voirin (1827-1887)[26] (fig. 9 and 10). This press was a wide-angle model employed for the printing of black and white and chromo chorographic and topographic maps.

Entre les Soussignés:

1° Mr. H. Voirin Constructeur Mécanicien demeurant rue Mayet n° 17 à Paris, agissant au nom de Mr. Rodrigues Chef de la Section photographique de la Direction Générale des travaux géodésiques du Portugal, d'une part,

2° Mr. Charre Modeste, mécanicien demeurant Rue de l'Ecole de Médecine, N° à Paris, d'autre part;

Il a été convenu ce qui suit:

Mr. Charre s'engage à aller monter et faire fonctionner à Lisbonne, pour le compte de la Section photographique de la Direction générale des travaux géodésiques du Portugal: Une machine à vapeur, les arbres de transmission; les machines à imprimer typographiques et lithographiques; une machine à dresser les pierres lithographiques, et différents autres appareils.

Il s'engage à faire comme mécanicien tout le travail nécessaire pour faire fonctionner ces diverses machines. Il s'engage à employer pour cela, tous ses soins et son activité. Il fera le travail de ses mains, mais, l'Administration de la Section Photographique devra lui fournir les aides et le matériel nécessaires. Ce travail sera fait conformément au projet qui a été fait et aux instructions données par les Chefs de la Section Photographique qui adjoindront au mécanicien, un typographe et un lithographe.

Mr. Charre devra donner aux ouvriers [illegible] toutes les indications possibles. Il devra faire essayer les machines l'une après l'autre et en sa présence. Il fera préparer à l'avance les rouleaux de la Machine Typo-

Fig. 10: Voirin's letter to J. J. Rodrigues, 1876 (IGP archive).

The drawbacks and costs of printing polychromatic maps in the traditional way were quite high as it implied the use of many stones. A new process of map colour printing with the aid of photography was devised by Charles Eckstein, director of the Dutch Topographical Department at The Hague. The combined prints of 4 stones (one for each primary colour: red, blue and yellow and one for black), allowed the printing of up to forty colours and tints. A carbon copy of a negative in wet collodion of the map was transferred to the light-sensitive surface of each stone. The stone was covered with an acid resistant coating of wax and bitumen of Judea. The hardened coating was put under a ruling machine which would cut grooves crosswise with parallel lines (8 to 20 lines on a millimeter). After being etched by a solution of diluted nitric acid, through a selective timing process, different tints of each colour would be produced on each stone after being rubbed on with one of the primary colours (blue, yellow and red) or black. Afterwards the stone was ready for the lithographic impression (fig. 11). The etching process was also applied to contoured maps (fig. 12). This half-tone process was similar to the one patented in 1882 by the German printer George Meisenbach (1841-1922)[27].

Eckstein attended the International Exhibition at Philadelphia (1876) presenting there a booklet with samples of maps and the description of his technique[28]. In the Universal Exhibition at Paris (1878) he exhibited maps photomechanically printed in colour. The Photographic Department of the Portuguese Geographical Institute and Rodrigues were also present at these two international exhibitions. The two cartographic institutions exchanged correspondence and a very skilled Portuguese cartographer, Manuel Dias dos Santos, was sent to The Hague to learn the Eckstein process[29].

Rodrigues improved an analogous photochromolithographic process, named chromocuprography, which used a copper plate instead of a stone as the support surface; as an etching solution he used a solution of iron (II) chloride (commonly known as perchloride of iron) and improved the halftone process by adding iron (II) oxide. These chromocuprographic essays were exhibited at the Universal Exhibition in Paris[30] (fig. 13).

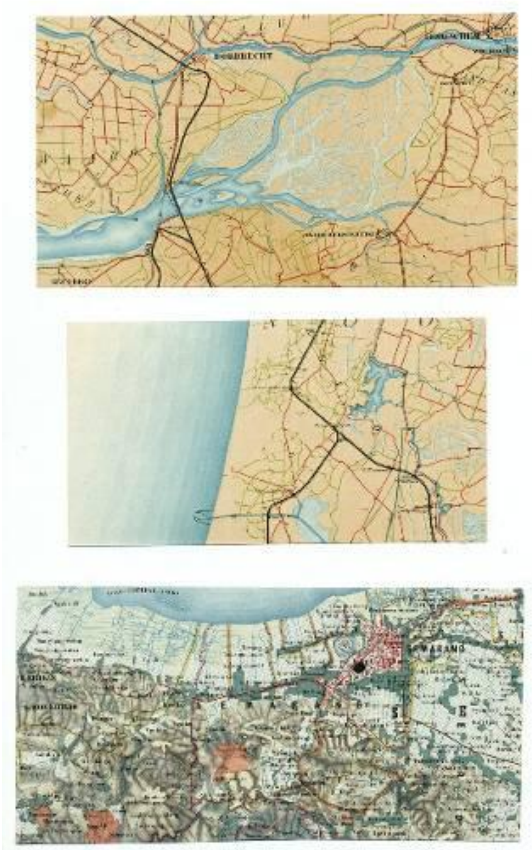

Fig. 11: Dutch photochromolithographic topographic maps (Eckstein,1876). (IGP archive).

Fig. 12: Topographic map (Eckstein; 1876).

The French researcher and photographer Louis Ducos du Hauron (1837-1920) attended the Universal Exhibition at Paris (1878), presenting several specimens[31] of his invented colour photographic system based on the trichromatic subtractive method[32]; he was awarded a silver medal. Hauron intended to produce low-cost three colour book illustrations using his indirect carbon colour separation process and in the 1870s developed with success the collotype technique with dichromated gelatin on glass and on copper. After several experiments he sent in 1891 a communication to the *Academie de Sciences de Paris, "Photography of colours: photomechanical reproduction of colours in unlimited number of copies"*[33] and filed a patent in 1892.[34] The principle of superimposing red, yellow and blue images was similar to the Eckstein process. The pigments were carefully chosen according to their compatibility with the wax used in the photographic technique and for their spectral qualities. They were organic (madder alizarin for red) and inorganic (lead chromate for yellow and ferric ferrocyanide for blue).

The research done on the development of cartography in the 19th century would allow us to conclude that the invention of photography and photomechanical processes were fundamental in the reproduction, scaling and colour printing of maps and charts. Furthermore:

- Photolithography and photozincography were mostly applicable to all maps in dot or line, except for very fine drawings; planographic prints from zinc displaced the use of lithographic stones as these were heavy and difficult to obtain in big sizes; the photoengraving methods were suitable for high quality printed maps.

---

[33] The full description of du Hauron's methods is in the book written by his brother Alcide, a scientist who collaborated with Louis Ducos du Hauron ; Du Hauron, A. Ducos (1897), *La triplice photographique des couleurs et l'imprimerie*, Paris, Gauthier-Villars et fils.

[34] French Patent of 15 years under No. 233,817, 20th August 1892.

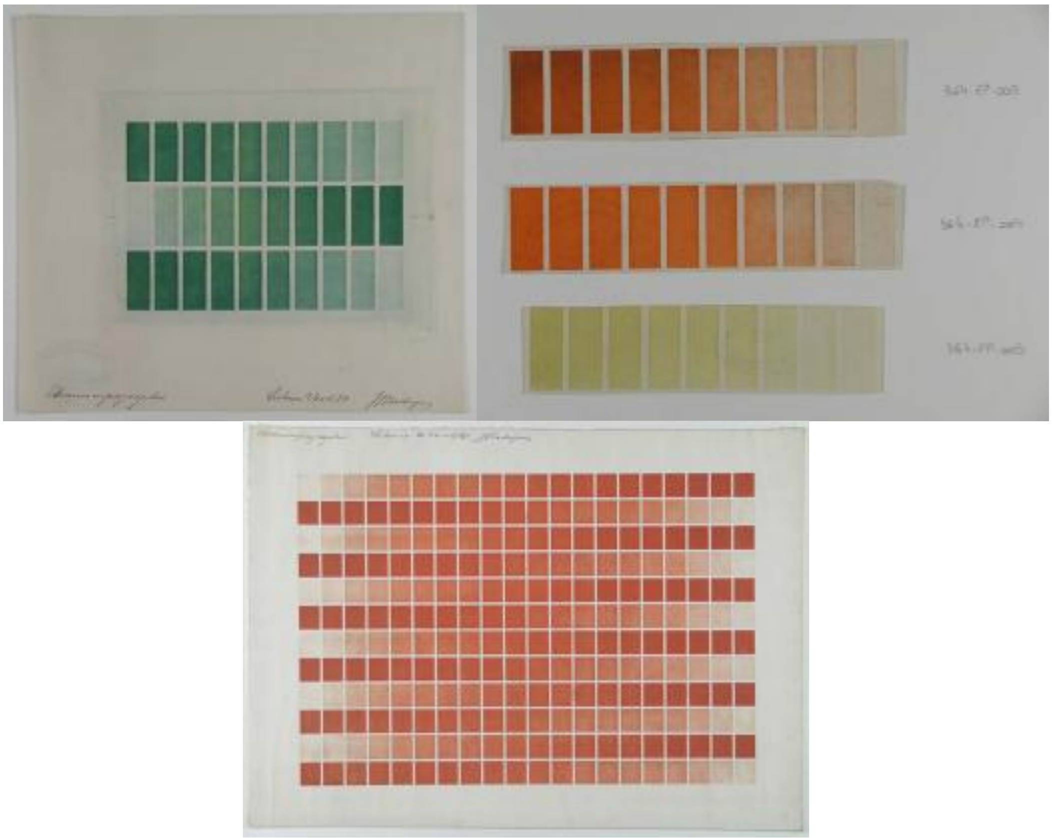

Fig. 13: Chromocuprographic essays (J. J. Rodrigues, 1877).

- Optical and photographic instruments were specially designed for the 19th-century cartography. However even before special cartographic cameras were installed, photography was also used to transfer line drawings into the sensitized stone or plate.
- Colour printing was essentially for geological maps. The Eckstein process, although time-consuming, was probably one of the best available at the time. This process was used in several European countries and received numerous awards in International Exhibitions at Philadelphia (1876) and at Paris (1878).
- The Photographic Department of the Portuguese Geographical Institute was considered one of the best in Europe. Important 19th-century photographic journals and books as well as geographical reports attested to its achievements. Several innovations on cartographic printing were introduced by José Julio Rodrigues: the use of tinfoil for photolithography, the typo-autographic process for the lettering on maps. He also did some improvement in the half-tone phototypographic process[35].

MOSCOW SOCIETY OF FRIENDS OF NATURAL SCIENCES AND DISSEMINATION OF SCIENTIFIC AND TECHNOLOGICAL KNOWLEDGE IN 19TH-CENTURY RUSSIA

Galina KRIVOSHEINA
Institute for the History of Science and Technology, Russian Academy of Sciences, Moscow, RUSSIA
krivosheina@gmail.com

Abstract

The Moscow Society of Friends of Natural Sciences, established by Moscow University in 1863, played a major role in popularization of science and technology in Russia. It was one of the first Russian learned societies to adopt large-scale scientific exhibitions as means of dissemination of scientific and technological knowledge. The exhibitions were aimed at popularization of certain branches of scientific knowledge that were developing or had been developed in the West but were unknown to Russian public. All of them were accompanied by scientific congresses to which eminent foreign scientists were invited. All provided Moscow with new science museums.

It is common knowledge that Western science was introduced into Russia by Peter the Great. Obviously, it was not an easy task, as in Peter's times in Russia, to cite A. Vucinich, "The scientists were few in number and their scholarly skills were rudimentary, to say the least".[1] Peter established in St-Petersburg an Academy of Science and Arts with gymnasium and university, which were to lay the basis for scientific inquiry in the country, to educate Russian scholars and to overcome generally negative attitude toward science and learning in the upper strata of Russian society and to interest lower classes in education and learning. He also invited to Russia a number of reputable European scientists, among them Nicolaus and Daniel Bernoulli, Christian Goldbach, George Bernhard Bilfinger, Joseph-Nicolas Delisle and many others. These efforts led to significant development of national science and education. During the next century a whole number of universities (among them Moscow University, 1755; Kazan and Kharkov Universities, 1803, *et al.*), schools (Konstantin Surveying School, 1779; Central Peoples School with Teachers' Seminary, 1783, *et al.*) and learned societies (Free Economic Society, 1765; Moscow Society of Naturalists, 1805; St. Petersburg Mineralogical Society, 1817; Russian Geographic Society, 1845, and many

[1] Vucinich A. *Science in Russian Culture. A History to 1860*. Stanford, Calif.: Stanford University Press, 1963, p. 69.

other) appeared in Russia and the practice of inviting foreign professors and academicians gradually came to an end. Nevertheless the problems inherited from the previous period still persisted.

The most serious hindrance to the further progress of science was the generally accepted attitude that science was a kind of foreign matter, strongly alien to Russian mind, all the more so as the languages, adopted in Russia for presentation of scientific ideas were Latin, French and German. In the beginning of the 19th century Academician Johann Philipp Krug (he was an expert in Russian history and numismatics) complained that in Russia there was no public for scientific writings, and that "generally everything that even savors of learning and exact research frightens readers here or is lamely omitted."[2] It is sticking enough, that even in the second half of the 19th century considerable part of Moscow liberal professors shared the idea that Russian people were not ripe for the understanding of intricate scientific ideas and deprecated organization of scientific exhibitions and international scientific congresses in Moscow.[3] So when in 1863 Professor of zoology and Director of Zoological Museum of Moscow University Anatoly Bogdanov established his Society of Friends of Natural Sciences (since 1867, Imperial Society of Friends of Natural Sciences, Anthropology and Ethnography –OLEAE) that, according to its Regulation,[4] was aimed at dissemination of scientific knowledge but not only at scientific research and advancement of natural sciences; adopted Russian as the only language of its publications; and proclaimed wide membership not limited by age, gender, social position or educational level (the only condition was that any member had to share the society's interests and aims and participate in its activities), it was no wonder, that OLEAE met strong opposition on the part of some Moscow professors and certain members of Moscow Society of Naturalists. They considered this to be destructive for Russian science and coined the new society not "friends" (*ljubiteli*) but "fiends" (*gubiteli*) of natural sciences.[5]

Nevertheless, Bogdanov managed to find support in many reputable Russian scientists, among them geologist, Professor of geognosy and paleontology of Moscow University Grigory Shurovsky who found among charter members of the society understanding and appreciation of his own ideas concerning development and dispersal of scientific knowledge in Russia. Shurovsky believed that "accessibility or popularization of natural sciences" was "a requirement of any educated country" and that "popularization of science is a method to influence the thinking of the whole modern society".[6] At the first meeting of OLEAE on May 14th, 1864 he was elected the first President of the new society and occupied this post for about two decades. In his Presidential address he emphasized: "…It is not deficiency in special works or scholarly issues that we feel. It's rather in people that could use these issues and further develop them…".[7] And the Society under leadership of Bogdanov and Shurovsky did its best to attract to scientific research as many people as possible. Scientific and especially popular activities of OLEAE also met with support from participants of the First Congress of Russian Naturalists (December 28, 1867–January 4, 1868) and especially its President, zoologist K.F. Kessler. The Congress even voted an appeal calling all Russian universities to establish learned societies on the model of OLEAE.

The first steps of the new society in popularization of scientific knowledge were not too impressive. At the first meeting of OLEAE Shurovsky offered that the society should organize excursions for people who were interested in natural sciences and presented "Rules for Geological Excursions", describing in detail the necessary equipment, sites of geological interest in the vicinity of Moscow, methods of geological research and presentation of geological data. In a year they were followed by "Brief Rules for Collecting Natural Objects", including zoological, botanical, paleontological and mineralogical collections,[8] prepared by a number of society members (A. Bogdanov, N. Senger, A. Fedtchenko, N. Kaufman and others), who also compiled educational collections of plants, insects, fossils, that could be bought from some Moscow booksellers. Nevertheless, Shurovsky's geological excursions, which started in the summer of 1864, were the most popular in Moscow. Shurovsky himself mentioned in his lecture at the First Congress of Russian Naturalists that sometimes these excursions announced in Moscow newspapers gathered up to 200 people of various age and rank and, in spite of the difference in their educational level; he always managed to keep up their interest. At the end of the excursions, to cite Shurovsky, "I invited the public to offer their questions to make clear the things that seemed to them not evident enough, and then started confabulation…"[9]

In 1864 OLEAE received as donation from Moscow archeologist and publicist A.Gatsuk two strangely looking skulls found during excavations of burial mounds in Podolsky uezd, not far from Moscow. This was the beginning of Bogdanov's interest to anthropology, which he considered to be an important part of zoology in general. Bogdanov was full of enthusiasm to compile a craniological collection of ancient inhabitants of Russia and Moscow region in particular. And though this idea was not completely new for Russian science (it was time and again expressed by Academician R. Baer, the first honorary member of OLEAE) Bogdanov with all his energy set this plan in motion. Together with some members of the society, he managed to do a really incredible thing –to make a whole number of Russian landowners explore their estates in search of burial mounds and grant permission for excavations on their lands. Some of them got so interested in anthropology, that they made excavations themselves (in spite of the fact that the Orthodox church would think this a highly questionable occupation) and sent to the society the skulls they found (this is testified by numerous letters published in OLEAE minutes). As a result, during the summer of 1865 OLEAE's anthropological collection was supplemented by 300 new items. Essentially this was the starting point of regular research in physical anthropology in Russia.

Also in 1864, when the Division of Anthropology was established in OLEAE, the society at Bogdanov's suggestion put forward an initiative to organize an Anthropological exhibition in Moscow and to establish a Department of Anthropology with Anthropological Museum by Moscow University.

Bogdanov already had some ideas concerning exhibitions. When in 1857 he made his first trip to Europe, he visited London and was greatly impressed by the Chrystal Palace and its exposition.[10] By that time this famous exposition hall of the 1851 Great Exhibition had been already moved from Hyde Park to Sydenham in the south outskirts of London. He derived from the story of the Palace some principal conclusions. First of all, he realized that an exhibition was a good means for popularization of scientific knowledge as it actually could attract a lot of people belonging to different social classes and having different educational levels, and that exhibitions brought money that could be used to develop certain fields of scientific education and research (Victorian England had already proved this by constructing the so called Museum land in South Kensington).

Besides that, he had some personal experience in exhibition-making.[11] As secretary of the Committee of Acclimatization of Animals and Plants of the Moscow Society of Agriculture, he organized two Acclimatization Exhibitions in 1858 and 1863. Both of them were a success, but if the first one was rather unpretentious, the Second Acclimatization Exhibition, held in the Moscow Manezh in 1863 was extraordinarily representative by Moscow standards. It was a real event (actually it was the first large exhibition in Moscow) and, what was more important, it helped the Committee to gather enough money to start the construction of the Moscow Zoological Garden.

It's obvious enough why Bogdanov suggested organizing an Anthropological Exhibition: it had to popularize anthropology as a science in Russia and it also had to bring money for the new Department of Anthropology. Unfortunately due to some financial and technical reasons, the society had to change its plans and the anthropological exhibition turned into an exhibition of ethnography and anthropology, and finally into an ethnographic exhibition with a small anthropological section (the Anthropological Exhibition was held in Moscow only in 1879).[12] So the first exhibition held by OLEAE was the All-Russia Ethnographical Exhibition. It was the first and very successful attempt of a large-scale scientific exhibition undertaken by OLEAE. During preparatory work for this exhibition the society worked out basic principles of its exhibition-making strategy which was used during organization of the two other great scientific exhibitions held by the society (Polytechnic Exhibition, 1872 and Anthropology Exhibition, 1879) and more unpretentious Zoological and Geographical Exhibitions of 1892.

In brief, these principles can be represented as follows:

1. Scientific exhibitions were aimed at popularization of certain branches of scientific or technological knowledge that were developing or had been developed in the West but were alien to the Russian public.
2. OLEAE attracted to preparatory work as many people as possible. Though the exhibitions were held in Moscow the society tried to encourage and instruct people even from far off regions of the country to collect necessary exhibits. This was especially helpful in the recruitment of new members and in establishing new affiliations in different parts of the country (in this OLEAE followed the example of the Russian Geographical Society which had its branches all over Russia). Sometimes these contacts were very useful for the society itself, as it was with the famous Turkestan expedition of A. Fedtchenko, which became possible only due to Turkestan governor K. von Kaufman, an active participant of the Ethnographical Exhibition.

[11] See: Raikov B.E. 'Anatoli Petrovich Bogdanov'…

[12] On the history of these two exhibitions see: Raikov B.E. 'Anatoli Petrovich Bogdanov'…; Krivosheina G.G. 'Rol' A.P. Bogdanova v razvitii zoologii v Rossii' [Role of A.P. Bogdanov in development of zoology in Russia]. In: *Istoria sociokul'turnykh problem nauki i tekhniki*, No 3. Moscow, 2004.

3. Before and during the exhibitions high-level lectures on the topic for educated public were combined with gratuitous scientific demonstrations and lectures for people with lower educational level.
4. Decoration of exhibitions was always impressive thus helping to memorize the main ideas of the exhibition: beautiful mannequin groups in traditional natural or household environment, giant plants, dinosaurs, mammoth, etc. Maybe it was not too scientific, but certainly memorable.
5. Each exhibition was accompanied by important scientific or cultural events. They also served as a good means to demonstrate achievements of Russian science as eminent foreign scientists were invited. In this respect political events, associated with exhibitions, appeared to be less effective, as it happened at the Ethnographical Exhibition, which turned into bacchanalia of Slavophilism.
6. Each exhibition provided Moscow with new science museums (Dashkov Ethnographical Museum, housed together with Rumyantsev Museum in the Pashkov House, the Polytechnical Museum, and the Museum of Anthropology of the Moscow University).

THE DIFFUSION OF NEW PAINTING MATERIALS IN 19TH-CENTURY PORTUGUESE TECHNICAL COURSES: THE CASE OF THE OPORTO INDUSTRIAL SCHOOL

Sónia Barros SANTOS
CITAR – Research Centre for Science and Technology in Art,
Escola das Artes, Universidade Católica Portuguesa, Porto, PORTUGAL
ssoniab@gmail.com

Abstract

Technical education in Portugal had its official beginning in 1852. Oporto Industrial School (in present time known as Instituto Superior de Engenharia do Porto – ISEP*) was then created. Its history is a testimony of the troubled early life of industrial education and training in the country. The survey of its historical archives and museum allowed pigments designation study and prices' comparison between traditional and modern synthetic products in the last years of the 19th century. These were analysed by colour range. The compilation of brands and provenance in fine arts materials acquisitions was also possible.*

Introduction

The outset of industrial and technical education in Portugal can be traced back to 1759 with the implementation of *Aula do Comércio* (Commerce lecture) in Lisbon, followed by nautical science (1765 in Oporto) and drawing (1779 in Oporto and 1781 in Lisbon). The *Academia Real das Ciências de Lisboa* (Lisbon Royal Academy of Sciences) is created in 1779. The outset of *Sociedade Promotora da Indústria Nacional* (National Industry Promotional Society) occurs in a politically and economically troubled period in 1822. In 1836 the polytechnic experiences are adopted in the country. The importance of secondary education is recognized and sciences applied to the arts and crafts are regarded as means to prosperity. In 1837 the *Conservatório Portuense de Artes e Ofícios* (Oporto Arts and Crafts Conservatory) and the *Academia Politécnica do Porto* (Oporto Polytechnic Academy) appear in Oporto, Portugal's industrial capital during the 19th century. The *Associação Industrial Portuense* (Oporto Industrial Association) is implemented in 1849. This association aimed at reaching prosperity through instruction of working class and the preparation of craftsmen. In order to achieve this, a school was also created. Finally in 1852, legislation determined officially the beginning of technical and industrial education and private initiatives were abandoned. Two schools appear in the following year: Lisbon Industrial Institute and Oporto Industrial School. Both schools suffered several reorganizations during the 19th and first half of the 20th centuries. Yet throughout this period, among other areas of study, courses and curricula of Oporto school included drawing, machines and models design, geometry, painting techniques or decorative painting as well chemical technology and chemistry applied to arts such as dyeing, stamping or ceramics. Pragmatism, labour market orientation and learning by imitation were some principles adopted. The School had a museum and laboratories for instructional purposes (fig. 1) [1-4].

Fig. 1: *Laboratorio Chimico* (chemistry laboratory) of Oporto Industrial School in the second half of the 19th century.

Integrated in a broader project concerning the introduction and circulation of new painting materials in 19th-century Portugal, the study of the historical archives of Oporto Industrial School/*Instituto Superior de Engenharia* (ISEP) and its museum allowed the compilation of information concerning materials, their prices and places of acquisition (figs. 2-7) in the last quarter of the century. Objects in the collection, cash books, bills and catalogues were elements analysed and discussed within the European context.

New pigments synthesis in the 19th century

The discovery of new elements such as cobalt (Brandt, 1739), zinc (Marggraf, 1748), strontium (Crawford, 1790), chromium (Vauquelin, 1797), Barium (Davy, 1808), cadmium (Strohmeyer, 1817) led to the discovery of new pigments mainly in the period between 1770 and 1900 [5]. The synthesis of modern colours answered some basic and urgent issues: the need of a broader palette (chromium, cadmium and cobalt-based colours allowed the enrichment or replacement of poor options in the ranges of yellow, green and blue colours) and the need of less costly materials (e.g. ultramarine blue, the only good blue pigment before synthetic pigments appeared was extremely expensive) (table 1). The textile industry demanded cheaper and larger quantities of new dyes and the growing awareness of some traditional colour materials' toxicity (pigments based in lead, mercury, arsenic, for instance) gave rise to the search of less or non-harmful colour agents [6-8].

Table 1: Main new synthetic pigments developed in 1700-1900.

Colour	Pigments	Year of discovery, author
WHITE	Zinc white Barium white	1781, Guyton de Morveau 1782, Guyton de Morveau
BLUE	Prussian blue Cobalt blue Artificial ultramarine Cerulean	1704-1707 Diesbach and Dippel 1803-1804, Thenard 1826-1828, Guimet 1789, Hoepfner
YELLOW	Mars yellow Turner or patent yellow Zinc yellow Chromium yellow Barium yellow Strontium yellow Cadmium yellow Cobalt yellow	1780, de Massoul? 1775, Scheele c.1800, Vauquelin 1804, Vauquelin 1809, Vauquelin 1809, Vauquelin 1817, Strohmeyer 1831, Fischer
GREEN	Scheele green Schweinfurt green Chromium oxide green Viridian Cobalt green	1775, Scheele 1814, Sattler 1797, Vauquelin 1838, Pannetier 1780, Rinmann
RED	Mars red Chromium red Silver red Iodine scarlet Cobalt violet Manganese violet	Early 19th century 1804-1809, Vauquelin 1807, Chaptal 1811, Courtois 1859, Salvétat 1868, Leykauf
BROWN and BLACK	Prussian brown Prussian black	Unknown unknown
All colours	Synthetic dyes	

Pigments in Oporto Industrial School: a 1889-1896 portrait

The survey and the data collected led to the study of prices and their relation among each colour range. Only pigments whose price per weight unit (kilogramme) was determinable could be considered. For the majority of the colours analysed, this meant the period from 1893 to 1896. The exception was yellow colours; the gap for these was 1889-1896. Pigments' historical names could also be compiled. The French names collected correspond to imported materials by *Araújo & Sobrinho*, a shop located in Oporto that began its activity in 1829 as a paper dealer and evolved selling a variety of goods. They represented *Winsor & Newton* in the second half of the century. Although the brand of these pigments was not mentioned in receipts, the fact that their names are written in French means that they also received different brands and from other countries of provenance, namely France, since the conversion is made from *francs* to *reis*, the Portuguese currency in late 19th century.

White pigments

Two classes of white pigments could have their price per kilogramme (Kg) determined. Among traditional whites, lead white appeared under the names *branco de chumbo* and *blanc d'argent* (*alvaiade* was also found but no data to establish unitary price was available). Zinc white was the only modern white present, under the names *branco de zinco* and *blanc de neige*.

At the end of the 19th century traditional and modern whites could be equally expensive, depending on their quality (average prices: $345/Kg –*blanc de neige*/zinc white; and $368/Kg –*blanc d'argent*/lead white). Yet modern zinc white ($190/Kg –*branco de zinco*) could be less costly than lead white ($240/Kg –*branco de chumbo*) (fig. 8). This is confirmed by importation in commerce statistics, price regulation of pharmacies' goods and other publications. Zinc white price dropped and lead white's was rather stable throughout the century [9-10].

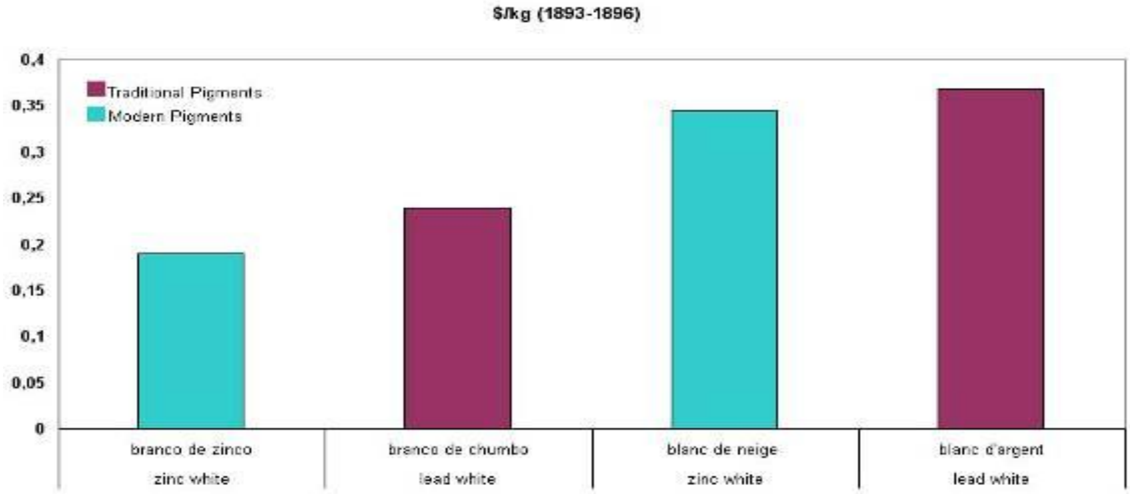

Fig. 8: White pigments: prices per weight unit (*reis / kilogramme*).

Blue pigments

Among traditional blues, only indigo could be priced per unit weight. It was named *azul indigo*. Blue ashes, mentioned as *cinza azul*, were also bought, but price/Kg was not possible to calculate. Four different classes of blue synthetic pigments were found: Prussian, artificial ultramarine, synthetic dye and cobalt blue. Prussian blue appears as *azul da Prússia*, *azul mineral* and *bleu de Chine*. Artificial ultramarine blue is named *azul ultramar* and *bleu outremer*. These could be classified as the artificial version of ultramarine because of their distinctive low price. A blue synthetic dye was also acquired, *bleu lumière*. Cobalt blue is referred as *azul cobalt*.

At the end of the century, there is a clear dominance of modern pigments in blue colour range. Artificial ultramarine was then one of the cheapest blue pigments (average price $700/Kg –*azul ultramar*/artificial ultramarine). Prussian blues prices showed larger variations depending in their purity and manufacture. *Bleu de Chine*/Chinese Blue, a high quality Prussian blue, was the dearest in this class (3$825/Kg) [11-13]. Cobalt blue, as other cobalt pigments, was confirmed as an expensive product still. Indeed, sold at average price 12$900/Kg, it is the most expensive blue pigment, 18.4 times more expensive than *azul ultramar*. Indigo, the only traditional blue pigment included was an expensive material too, sold at 9$600//Kg (fig. 9).

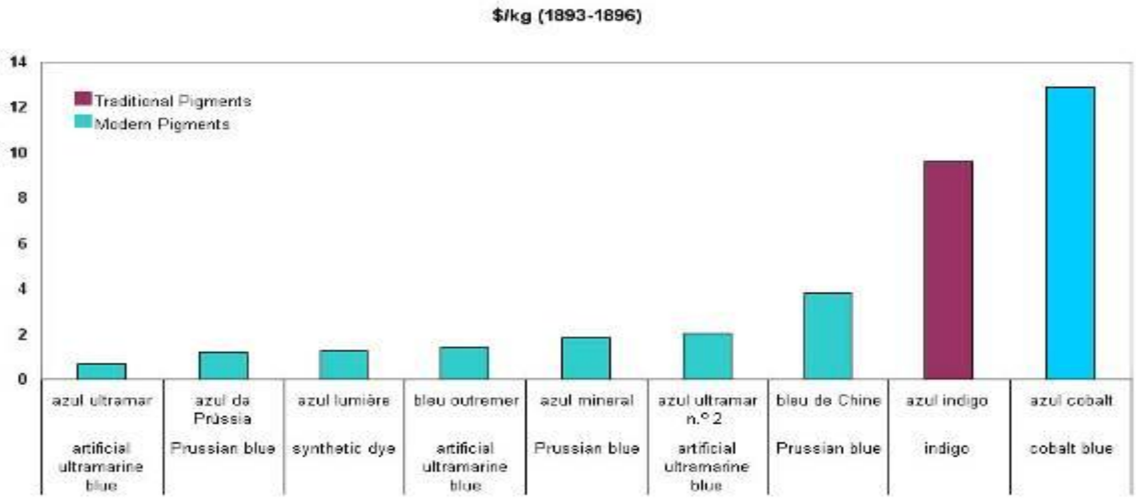

Fig. 9: Blue pigments: prices per weight unit (*reis / kilogramme*).

Yellow pigments

Four traditional classes of yellows were found: yellow ochres, Naples yellow, Indian yellow and gamboge. Yellow ochres are *ocre*, *ocre fino*, *ocre amarelo*, *amarelo de Itália* and *ocre d'ouro*. Naples yellow is referred as *amarelo de Nápoles*, indian yellow as *indien* and gamboge as *gomma indiana*. Two modern classes of yellow were present: chromium yellow, named *chrome foncé* and *chrome clair*, and cadmium yellow, listed as *cadmium*. Yellow synthetic dye *anilina amarela* was also present but was not considered since no price per weight unit was determinable. Yellow ochres and Naples yellow were clearly inexpensive traditional pigments (average prices eg $060/Kg –*ocre fino em pó*/yellow ochre; $920/Kg –*amarelo de Nápoles*/Naples yellow) as chromium yellow was among modern ($870/Kg –*chrome clair*/chromium yellow). Cadmium yellow was the most expensive modern yellow pigment in the group. Sold at average price 9$200/Kg, it was 153 times more expensive than the cheapest ochre. Two traditional classes of pigments have the dearest prices, namely Indian yellow and gamboge. More than twice the value of cadmium yellow, their average prices were, respectively, 20$700/Kg and 21$000/Kg. These two materials' high prices are confirmed in foreign technical literature [14-15] (fig. 10).

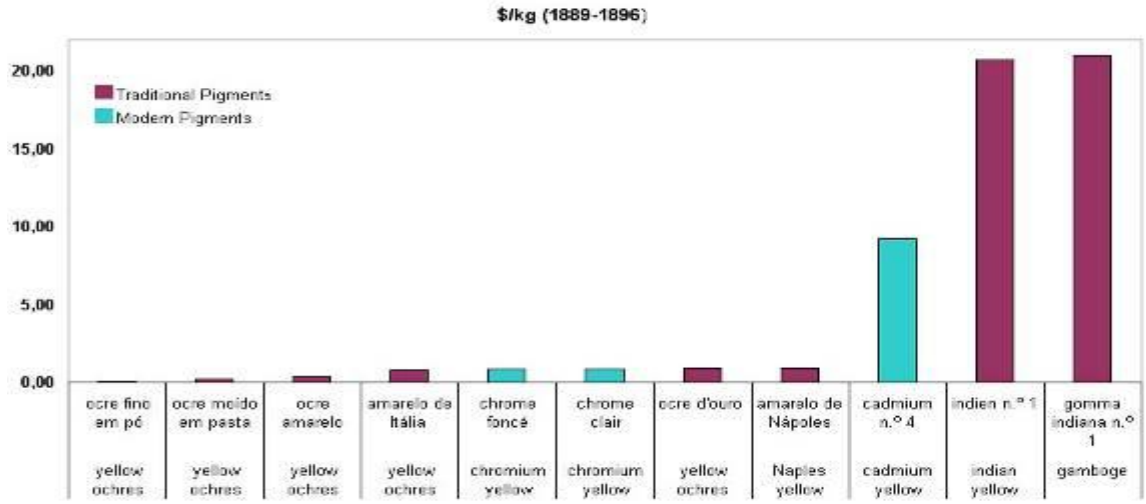

Fig. 10: Yellow pigments: prices per weight unit (*reis / kilogramme*).

Green pigments

Three different types of traditional greens were identified: buckthorn, mentioned as *vert Chine*; verditer was referred as *cendre verte* and *vert mineral*; and sap green appeared under the name *verde bexiga*. Also three modern greens were found: Schweinfurt green was present as *verde de Paris* and *vert Veroneze*; chrome green, a composition or mixed green, is listed under the names *vert de chrome* and *verde de chromo*. Finally viridian is *vert emeraude*. The vegetable green colour buckthorn is the most accessible ($046/Kg –*vert Chine*), followed by Schweinfurt greens and green verditer. Schweinfurt greens (*verde de Paris*, *vert Venoneze*) and verditer (*cendre verte* and *vert mineral*) prices were variable. Chromium-based greens like chrome green and viridian were expensive (3$220/Kg –*vert de chrome n.º 1*/chrome green; 5$750/Kg –*vert emeraude*/viridian). Surprisingly, traditional sap green presented a high price (5$300/Kg –*verde bexiga*). This raises the possibility it might be of different nature, unrelated to its designation [12,16] (fig. 11).

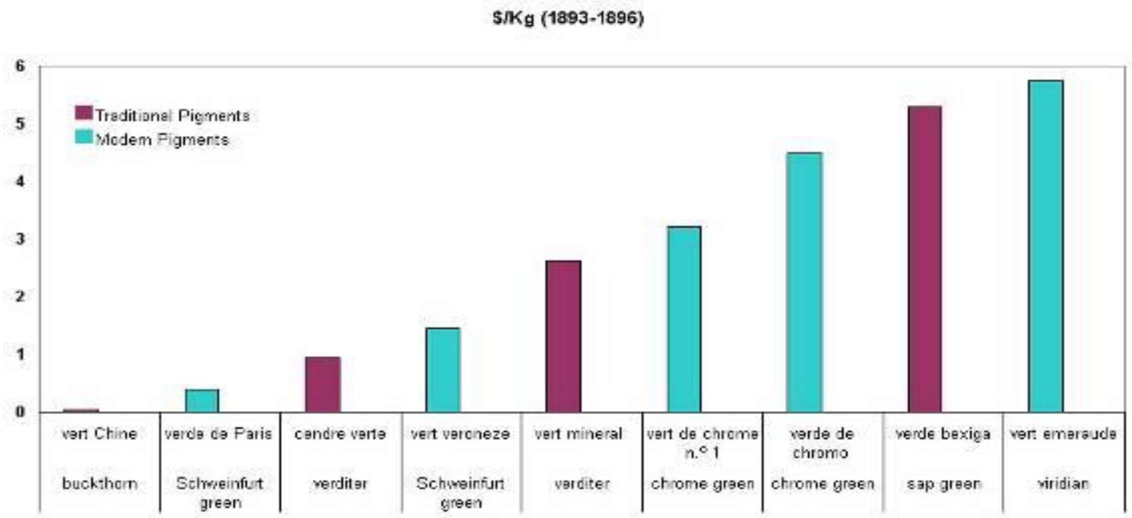

Fig. 11: Green pigments: prices per weight unit (*reis / kilogramme*).

Red pigments

A larger number of classes and dispersed prices were detected in red pigments: five traditional classes and four modern. Traditional reds include red ochres, red lead, dragon's blood, vermilion and cochineal lakes. Red ochres appear under the designations *roxo rei*, *sanguínea*, *vermelho indiano* and *vermelho de Veneza*. Red lead is *rouge Saturne* and *azarcão*. Dragon's blood is *sang dragon*. Vermilion is *vermilion* and cochineal lakes are named *laca carminada* and *carmim*. The four modern red classes found were: chromium red that appears as *vermelho de chromo*; synthetic dyes include different materials and names like *laque dahlia*, *magenta*, *rosa bengala* and *laque geranium*; Mars violet is listed *violeta de Marte* and *violet Mars* and finally cobalt violet is *violet cobalt*. Red ochres had different prices but can be considered inexpensive pigments. Referring exclusively to this class, *roxo rei* was cheaper than *sanguínea, vermelho indiano* and *vermelho de Veneza*. Their prices are similar to red lead's and to chromium red, the only new pigment belonging to the less costly. *Almagre*, another red ochre, has a price at a different level, together with vermilion and dragon's blood but cheaper than cochineal lake *lacca carminada* (fig. 12-a). A division in red pigments is noticeable relating prices and categories. The major distinction is that the group of more expensive pigments (3$500-20$000/Kg) is mostly constituted by modern synthetic red pigments. The exceptions to this rule are, on one hand, the accessible chromium red (*vermelho de chromo*), and on the other hand, safflower (*rouge cartham*) and cochineal lake (*carmim*), traditional yet expensive materials. Once again, as in blue pigments, a cobalt pigment, cobalt violet, is the most expensive material. It was sold at 18$400/Kg. This value is 307 times more expensive than *roxo rei*/red ochres ($060/Kg) and 6 times the price of *lacca carminada n.º 2*/cochineal lakes (2$950) (fig. 12-b).

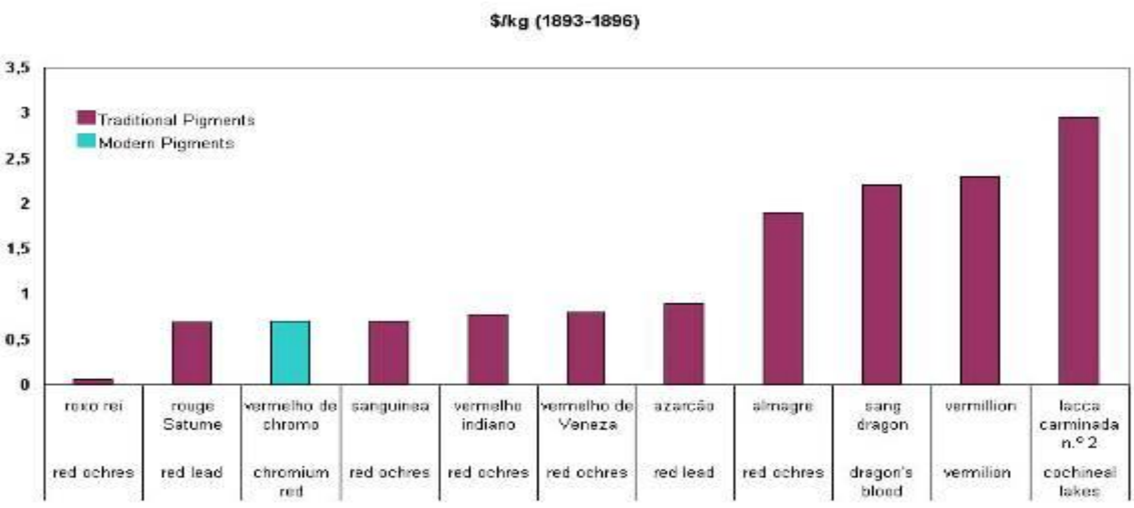

Fig. 12-a: Red pigments: prices per weight unit (*reis / kilogramme*). Values 0-3$500.

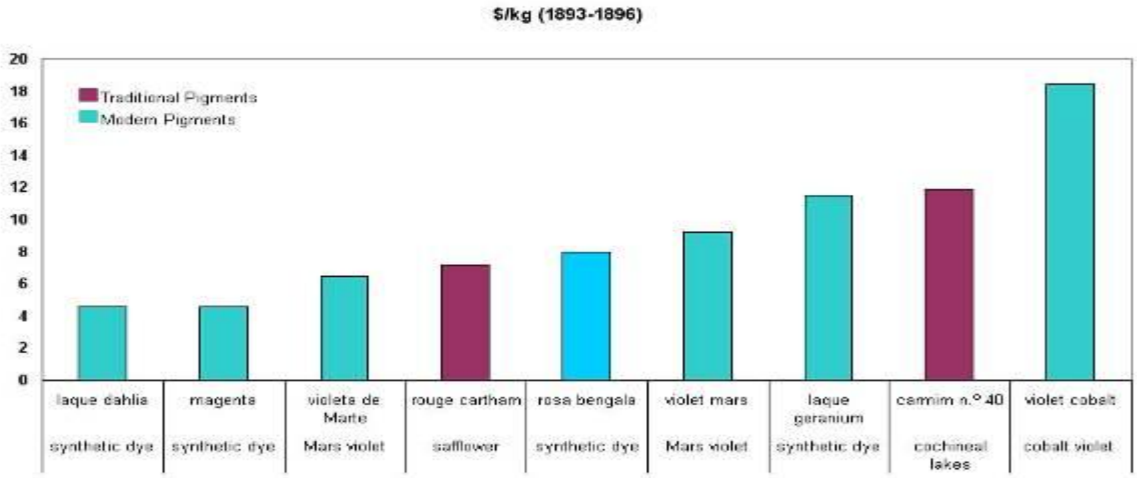

Fig. 12-b: Red pigments: prices per weight unit (*reis / kilogramme*). Values 3$500-20$000.

Brown and black pigments

The comparison of prices could only be made for traditional black and brown pigments. Umber was named *terra de sombra* (*natural*) and *terre ombre*, Sienna earth was *terre sienna*, *terra de Sienna* (*natural* and *queimada*) and *terra de Itália* (*natural*) and finally, ivory black was present as *negro de marfim*. Although not included because their price per weight unit could not be determined, other pigments, both traditional and modern, were found in bills. Considering traditional classes, black lead was named *plombagina*, black earth was *terra preta*, Indian ink was *pau de Nankin*, sepia was *sépia* and umber was *sombra*. Regarding modern pigments, synthetic dyes both brown and black were present respectively as *anilina castanha* and *anilina preta*. The prices variation is small as brown and black were usually inexpensive pigments. The cheapest, *negro de marfim*/ivory black was sold at the average price of $340/Kg and the most expensive, *terra de Itália natural*/Sienna earth at $780/Kg (fig. 13).

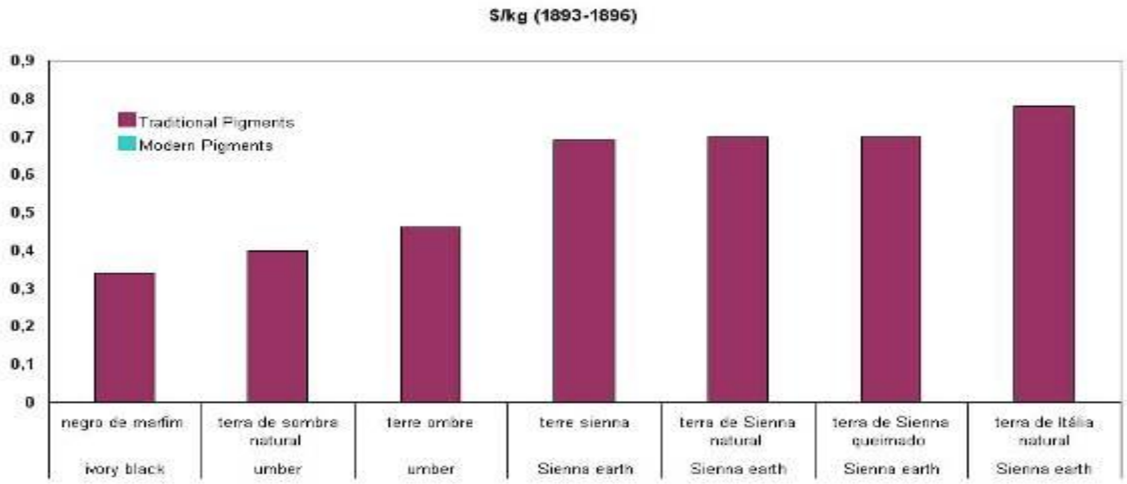

Fig. 13: Brown and black pigments: prices per weight unit (*reis / kilogramme*).

Oporto Industrial School acquisitions: Shops and Brands

In 1817, in a publication about drawing and painting, Ferreira da Silva describes the preparation of paints. The author has one clear goal: "*avoid dependence from English and French paints*" [17, p.116]. This short observation testifies the ongoing revolution in painters' craft as specialized tradesman and colourmen make ready-to-use painting materials available. International influence is found in Portuguese 1840's publications as French, English or German books and newspapers circulate in Portugal making knowledge accessible and diminishing the gap between periphery and European countries central to the development of these products. Progress and prosperity were expected results from political investments in education and arts by several governments in the second half of the century. Authors repeat that economical advantages to the country would arrive from production effort and innovation [18-19]. In this context, documentary sources include information about machines, factories, production of goods, diagrams, recipes and secrets for arts and crafts. Instructions to make painting materials were also included in this general trend. Industrial development incentives can also be seen in measures as the creation of industrial and technical schools, the opening of industrial museums and regular industry exhibitions.

Table 2 shows the acquisitions made by Oporto Industrial School of fine arts materials in the period 1876-1896. National, mainly local, and occasional French stores were found. Table 3 depicts brands, products and date of fine arts materials acquisition. French brands are preponderant. The probable importation of materials is not detected in most receipts.

Table 2: Painting materials acquisitions by Oporto Industrial School (1876-1896).

Shop	**Purchase year**	**Address**	**Product**
Benjamin Barral	1876-1882	Faubourg Saint-Denis, 80, Paris, France	Pigments and dyes
António Fonseca de Moura	1888	Largo de S. Domingos, 99, Oporto, Portugal	Stucco plaster
Joaquim António Cardoso de Almeida	1888-1892	Praça Carlos Alberto, 9-10; Oporto, Portugal	Pigments and dyes, varnishes, solvents, chemical products

Petit Buisson	Drawing charcoal	**1892**
Venitum pour le trait	Drawing charcoal	**1892**
Reeves	Drawing and watercolour set	**- (1889? 1891?)**
J.& A. Molteni	**Drawing set**	**- (1889? 1891?)**

Conclusions

Traditional pigments persist throughout the century. The main pigments referred in contemporary foreign technical literature were found in Oporto Industrial School receipts.

Regarding fine arts materials, French provenance was dominant in the School acquisitions in the studied period.

The access to synthetic materials at the end of the century is confirmed and some modern pigments were then less expensive materials than traditional ones. For instance, among blue colours, artificial ultramarine had become the cheapest blue pigment.

Considering modern pigments, chromium-based colours were sold at low prices, with the exception of viridian. Instead, cadmium- and cobalt-based pigments were expensive colour materials throughout the entire century as one can confirm in the late years.

Regarding traditional pigments by colour range, materials such as Indian yellow, indigo and cochineal were among the most expensive materials respectively in yellow, blue and red pigments.

Technical literature shows the availability of materials from the French supplier *Lefranc* [20-21] and in the second half of 19th century *Araújo & Sobrinho* sold Winsor & Newton. In early 20th century other brands such as *Morin & Janet* and *C. Bourgès* are documented [22-23].

THE CIRCULATION OF KNOWEDGE ABOUT SYNTHETIC COLORINGS IN THE COMPANY *LA ESPAÑA INDUSTRIAL*

Assumpta DANGLA, Mònica DÒRIA
Museu de l'Estampació de Premià de Mar, SPAIN
assumptadangla@gmail.com
mdoriat@gmail.com

Abstract

The present communication is a study about the circulation of textile chemistry knowledge in the moment of transition from the use of natural to synthetic colourings for textile printing. The company La España Industrial*, the most important textile factory in Spain (1847-1980), progressively incorporated new synthetic colourings, which during the second half of the 19th century coexisted with natural colourings.*
The discovery in England in 1856 of new synthetic colourings revolutionized the production in factories and changed the forms of communication of knowledge on the subject of chemistry applied to printing.
In the case of natural colourings, the transmission of knowledge was traditionally made under a great secrecy. With the discovery of new synthetic colourings, the forms of communication changed and new tools of communication on formulation and application of colourings were born.
The Museu de l'Estampació de Premià de Mar, a museum specialized in textile printing, preserves an extended collection of formularies and a documental archive of the company La España Industrial. In this collection there are several witnesses of the incorporation of the new chemical knowledge.
In our journey, various aspects of the period of natural and synthetic colourings are revealed on La España Industrial*. In the first place, we present a collection of unedited formularies of the museum, witnesses of the progressive incorporation of synthetic colourings and of the coexistence with natural colourings. We also present the catalogues of colourings edited by chemical industries that were used in the factory.*
Other unedited documents are also discovered, like the correspondence that the company sustained with chemical companies, Spanish and foreign scientists. In our route, we will reveal the main actors of the change in the factory that implanted the new discoveries, and the tools that they used for the transmission of this knowledge.

Introduction

The knowledge on natural and artificial dyes has been spread during the history in different ways. On one hand, the exchange and transmission of knowledge on traditional colours from plants, animals and minerals were established between the artisans grouped in guilds. The transmission of the technical process for dying and secret colour recipes in many cases were given orally; ateliers and manufactures preserved with extreme caution the formulation to obtain textile colours. We can find technical written documents and books of formulas of the 17th, 18th and 19th centuries in the Biblioteca Nacional de Catalunya, Arxiu de la Junta de Comerç and Arxiu de la Casa Ardiaca de Barcelona.

The present communication pretends to announce unpublished documents preserved in the archives of the Museu de l'Estampació de Premià de Mar, having as reference *La España Industrial* factory, which with a different purpose have been tools for knowledge about the use of natural and synthetic dyes within the company.

With this communication we also want to show the technical and scientific evolution in the factory, in Catalan and European context, analysing how *La España Industrial* (henceforth abbreviated: LEI) applied new chemical discoveries on textile colours to its laboratories and to the final product, the printed and dyed fabrics.

Introduction to natural colours

When we speak about textile colours, it's necessary to establish a clear distinction between the colours for dyeing or dyes used in liquid state submerging the clothes, and the colours for printing designs, previously engraved on moulds, over the fabrics. While the first ones were already known and applied in Europe since the Neolithic, the others began to be used by European printers in the 17th century, thanks to the import of calicos, a multicolour printed cotton from India and China.

Until 1856 printers and dyers used only natural colours, commercialized in dust, kneads or solid blocks, that little by little happened to be substituted by artificial ones. So much, the difficulty in the arrival of natural colours from the colonies and the overhead cost of some of these products are factors that drove the studies of chemists to elaborate synthesis colours in the laboratories.

Some natural and local colours were substituted during the second half of the 18th century for exotic products from American colonies. And one century later synthetic colours would take the place of natural local and also exotic ones.

In the case of Mediterranean blue, extracted of the leaves of the plant *Isatis tinctoria*, used since the Neolithic, the European import of indigo blue during the 16th century threw down whole regions devoted to the farming of *Isatis*. After their recovery during the 18th century, *Isatis* was again substituted, because of the interest by chemists in the 19th century to know the composition of indigo blue trying to imitate it to the laboratory. Nowadays *Isatis tinctoria* has been replanted in Tolouse, France.

Since ancient times Europe and Orient extracted red colour from an insect called *Quermes* and also from the root of the plant *Rubia tinctorium*. The cultivation of this plant in Spain –Catalonia– and France –Alsace and Vauclusse– was gravely affected in the 18th century because of the introduction of a red exotic pertinent insect from Central American colonies, called *Dactylopius coccus*, that became a sign of distinction between the richest classes.

In Catalonia, apart from the blue *Isatis* and the red *Rubia*, dyers had used many other autochthonous plants to elaborate natural textile colours.

Catalonia and the knowledge on science of colour

Catalonia stands for having been during the 19th century and until the last quarter of the 20th century, a textile producer centre of first order and, between the many specialities, takes a relevant role in the printing industry. Since the beginning of the Catalan textile printing industry, there was a worry to be up to date on the scientific novelties to equate to the European level.

The finding of synthetic colours in the 19th century supposed a revolution in a process that modified the internal and external relations of the manufacturing and factories of textile printing and dyeing. The findings changed the ways of transmission of these knowledges into new channels of communication (universities, trips to foreign countries).

In many documents we can see how knowledge crossed borders and how technicians established contact with companies from other countries. Knowledge travelled with manufacturers and scientists. In Catalonia, Carles Ardit and Josep Vallhonesta left an important bequeathed writing. Ardit worked in factories of France and Switzerland (1814-1817) and in 1919 published in Barcelona *Tratado teórico-práctico de la fabricación de pintados e indianas*, in two volumes, where he collected the formulas of all the local and exotic colours. However, he considered better to promote fields suitable to the Catalan climate. The historian Agustí Nieto defines Carles Ardit as a mediator of knowledge, between the South-European culture and the Northern industrial culture, and also as a mediator in the context of the Catalan industry.[1]

---

[1] NIETO I GALÁN, Agustí, "Secrets i receptes. Carles Ardit i el "Tratado teórico-práctico de la fabricación de pintados e indianes." Conference course *La indústria de les indianes a Barcelona, 1730-1850*, Barcelona, 2011.

Another protagonist of the innovations and changes in Catalonia, is the industrial engineer in chemistry Josep Vallhonesta (1835-1899), who introduced in Catalonia the system of determination of colours invented by the French chemist Michel Eugène Chevreul. In one of Vallhonesta's works, *El Arte del tintorero*, in 1880, the coexistence between natural and artificial colours is obvious.[2]

The factory *La España Industrial*

In this study we have taken as a reference LEI, the biggest factory in Spain, which initiated its activity in 1847 in Barcelona and was active for more than 100 years. It outstood for being the most prosperous textile company in the country, and one of the first one involved in all the textile processes, spinning, weaving and finishing, which include dyeing and printing. In the printing and dyeing department there were ten active cylinder machines printing continuously.

LEI is a perfect example of industrial and scientific development, as the factory endeavoured a constant process of research towards innovation and implementation on both technical and scientific fields.[3]

LEI had an outstanding position among calico manufacturers as a number of foreign experts were hired, coming mostly from Alsace. Local Catalan workers received the necessary training. Among the first ones stands Martin Ziegler.

The Museu de l'Estampació de Premià de Mar preserves an important collection of textile sample books and colour formulation books for dyeing and printing; also original drawings and administrative, scientific and technical documentation. A group of 120 formulation books, from 1860 to 1915, give us a lot of information about the products employed in the colour processes, the names of some technicians, and the origin and name of the providers.[4]

The use of dyes in LEI

For more than 50 years, natural and synthetic dyes were used at LEI indistinctly and simultaneously. New synthetic dyes did not set aside traditional natural colorants. We can establish three periods in regard to the use of different kinds of dyes. The first one would start at the very foundation of the factory at 1847 until 1866. The time span of 1867-1900 will see a progressive inclusion of new synthetic dyes. Finally, by 1900-1910 the old methods will be progressively abandoned and the use of natural dyes will be discontinued.

From the first period –when only natural dyes were used– the museum keeps a small sample collection featuring some similarities. Within these sample documents a letter dated from March 1860 mentions the purchase of several pigments, like garance, pomegranate flower, gall black, quercitron and sumac, all of vegetal origin.

In 1856, the English chemist Sir William Henry Perkin accidentally discovered the first synthetic colorant when he tried to synthesise quinine. From then on, Perkin developed the first synthetic dye: mauveine. Three years later, Verguin found the fuchsine, and Lauth methyl violet (1861). In 1862 August Wilhelm von Hofmann, the violet bearing his name; and Bismarck a new brown. By 1863, Lightfood invented the aniline black and in 1868 the German chemists Graebe and Liebermann synthesised alizarin.

During an extended period of time, spanning until the early 20th century, natural and synthetic colours will coexist on the factory, like other European factories will. LEI started adopting these new discoveries and substituted traditional methods gradually.

The first documented evidence about the application of synthetic dyes at LEI dates from 1867. The form "Colores vapor", displays a printed sample with fuchsine and another one with Bismarck brown. On the same form aniline green can as well be found. That same year, new dyes had already been introduced, although there is no written evidence of a possibly

ROQUÉ i J. ARBÓS, *Tratado práctico del blanqueo y tintura de la lana, redactado conforme a los principios, práctica y demostraciones de la química moderna y acompañado de un atlas conteniendo 100 colores fijados sobre dichas materias*, 2 vols., Barcelona, Imprenta de la viuda e hijos de Mayol, 1846.

[3] "LEI was one of the first manufacturers of printing fabrics. It was possible because of the figure of the chemist director and many foreign special technicians. (...) Alsatians (...) local workers, who learnt the processes from the foreign ones." (GUTIÉRREZ I MEDINA, M.LL., 1997, 233).

[4] Most of the products came from Germany and France, although in Catalonia we can also find providers. Ramon Monroig's factory, in Barcelona since 1844, was the first manufacture of colours for the Catalan textile printers. Leopold Sagnier found the first factory of synthetic colours in Catalonia in 1881, providing Spain and Portugal, but the factory depended too much on German providers. (CABANA, Francesc, 1992, 263-272). Joan Timoleó Cros, chemist manufacturer, provided chemical substances to *La España Industrial*. Timoleó was often a mediator of foreign colours. (GUTIÉRREZ I MEDINA, M.LL., 1997, 242-244).

earlier adoption, since there are no records prior to 1850. The use of Hofmann's purple was documented at LEI only 10 years after its discovery, but we cannot discard an earlier use.

However, from all the available documentation, no reference is made to the mauveine. Probably its steep price discouraged LEI to use it.

On the other hand, aniline black was adopted quite early. Aniline black is the residual result of industrial processes applied on coal tar. Coal tar was obtained from the reaction with hydrochloric acid yielding an intense black pigment. This new dye implied an important breakthrough for its resistance to light and washing. In 1868, this dye is referenced to as "Negro A" on form number 6064.

Much like aniline, products derived from distillation of tar are numerous. Many of them are suitable for the preparation of dyes and colorants, for instance: benzene, naphthalene, anthracene, from which many colours can be extracted.

1868 was a crucial year in this revolution. German chemists Graebe and Liebermann succeeded in preparing artificial alizarin. This was an important benchmark as it could substitute natural pigments, resulting on lower prices although this influenced negatively the production of madder.

Artificial alizarin found a great commercial success although it impacted deeply on the farming of madder, necessary to produce alizarin. Although the usage of artificial alizarin was ceased on many factories, LEI continued to employ it until 1880 along with its new artificial substitute.

The first attempt to use artificial alizarin was probably around two years after its discovery. The accounting books, with information about dye providers from 1870 to 1873 (MEP 7061), reference the Chancel alizarin, also called "penkoffin", an allegedly artificial pigment. However, we have actual proof that in 1874 LEI purchased some important amounts of artificial alizarin from the German company BASF.

LEI hired Spanish and foreign workers alike aiming to introduce new discoveries. An evidence of these innovations are the research work and notes taken down on the test record books.

It is interesting to observe that the aim of the tests was to find a substitute for natural pigments. On form MEP 7062 (from 1872) some test notes show an attempt to change a base colour to aniline grey using albumin. The results were not quite satisfactory. On the next page of the notebook, Heinrich Siegle (from Stuttgart) would try to "*remplacer le cachou de l'albumine pour une lacque*".

The museum preserves a similar document from the same year (MEP 7060), which brings together a series of tests with both synthetic and natural colours. It is remarkable a study dedicated to Prussian blue, discovered in 1774, and which is considered to be the first chemical pigment. The second part of this notebook is dedicated to studies about the properties of the water used, tests with natural pigments and aniline dyes, Hofmann's purple, etc. By the end, a study by M. Courton et Cie. from Mulhouse (France) can be found about the application of the naphtylamine maroon.

It is remarkable to observe how the tests tried to replace a natural pigment for synthetic substitutes. On two separate tests, carried out by Heinrich Siegle and by Courton, both strive to find new colorants in order to substitute old formulae. The main purpose was to reduce production costs and obtain more solid and resistant colours and improve fastness against water and light.

Two of these mentioned forms conclude with a study about the water used at LEI, since its quality is paramount to obtain optimal printing results on textiles. The factory took great care on analysing the water. Therefore, chemists played a central role in the factory. They were required to have a solid education and experience. It is not casual that some chemists achieved the direction of the company.

New discoveries are not adopted right away and the implementation of new colorants is gradual. This coexistence of traditional and newer methods is reflected on the documentation preserved by the museum, with special attention to document MEP 6078, the most revealing document about this coexistence.

The book summarises the time span between 1860 and 1880, providing evidence of the implementation of new colours. This manuscript contains the lists of colours and materials used to obtain the colouring paste, a moment where we can pinpoint exactly when synthetic dyes started to be employed.

Over the 1870s a few more discoveries will appear on stage. On 1872: methyl green. On 1873 cachou de Laval, 1874 Eosin, chrysoidine on 1875-6, alizarin blue and malachite green in 1877, briebrich scarlet in 1878. The same year Baeyer synthesised indigo, although it was not commercialised until 9 years later (1897).

Form number MEP 6068, spanning from 1878 to 1880 records for the first time the use of methyl green, a dye still being utilised nowadays.

By 1876, Mr Caro, an important chemist devoted to colour synthesis, finds the methyl blue which will be applied on LEI until the very end of the 19th century and which is repeatedly reported on samples and forms. At that moment, it was a good alternative to indigo. The most remarkable achievements at the time were the application of methyl blue and green.

From this period of time, it is important to highlight the document MEP 4957, a quite elaborated writing where we can find studies and solutions aimed to create the colouring paste, the preparation of dyes as well as colours applied by steam. This document allows us to understand the complex processes involved on tincturing and printing fabrics, especially on a very valued and bright colour: Adrianopolis red.

MEP 4957 reflects the abundant use of Prussian blue or Guignet green, which could be considered as a previous step towards a total adoption of chemical dyes. Eosine and chrisodine (which will be employed some years later) are mentioned as well.

Concerning the other dyes discovered during that decade, from Brieblich scarlet, malachite green and Cachou de Laval, we have found no trace of them. Cachou, in its origin is extracted from trees bark, and it is widely documented on the papers, but references to Laval are not made. Probably this is due to being a rather matte brown tone not allowing distinguishing whether it is synthetic or not. Any further information should be taken by a specialist in chemistry.

The museum preserves other documents providing evidence of tincture application and printing, including formulae and the development of a theory toward printing. Usually, the forms were meant to be exclusively for internal documentation aimed to serve as a knowledge database on the laboratory. However, this specific document seems to have been addressed to the director of the factory, Sr. Muntadas, who was always very attentive to innovation and new discoveries.

Over the 1880s some discoveries were made: vacanceine, benzopurpurine, Congo red (1885), Para red, alizarin yellow (1887), rhodamine and paranitriline (1889).

Congo red was discovered in 1884, but the only evidence of its use at LEI is recorded on MEP 5748 during the 1890s. On the other hand, benzopurpurine was copiously used over these years.

On the incoming record book “Entrada de materiales” (MEP 6067) we can find a comprehensive inventory of all purchased materials during 1885-86 until 1900. This document has allowed us to establish when new dyes started being used, like rhodamine, and alizarin yellow, discovered around 1887. LEI will swiftly adopt these new discoveries.

A significant piece of information –the form reference MEP 4959– shows us that paranitraniline was introduced the very same year of its finding, in 1889. That year, other forms and documents state the use of derivatives of benzene, such as chrisamine, benzoaurine, azo blue; as well as alpha-naphthylamines.

As a matter of fact, the relations with foreign dye producing factories were solid and stable. We can attest this on a book from the mid-1890s (MEP 6087) quoting the most outstanding dye producers like BASF and its branch Granier & Co., DV Rohne Leverkus and the subsidiary Pfaltz Hahn & Co. and Friedrich Bayer & Co, through its salesman Alfredo Riera.

The 1890s will bring new dyes and will consolidate former materials. It is relevant to mention alizarin bordeaux, diamine green, direct dye-sky blue, direct black, vidal black, etc.

Black and blue were important tones to understand the changes on those times. Until the late 19th century, aniline black was widely used, but it will be replaced by new discoveries, especially by direct black around 1908 (form ref. MEP 6115).

A similar situation applies to indigo. On 1878 Von Baeyer found the formula to synthesise indigo but it was not commercialised until 1897. The alternatives until then were mainly: natural indigo, methyl blue, alizarin blue and aniline, as well as other chemical derivatives.

Although chemical and natural dyes available options were quite wide, tincturing with natural indigo will prevail for some time. On form MEP 6139 from 1885 we find a detailed explanation of a traditional tincturing process with natural indigo based on oxidation. This document is of some importance as the main concern addressed is the endurance of dyes. An additional note corroborates the use of direct blue and the application of naphthaline blue on 1897. However, we will not find any mention to synthetic blue until 1912.

When chemists attempted to use synthetic dyes, they obtained the raw materials from the providers including even catalogues with exhaustive instructions. Even so, it was necessary for the workers at LEI to have an extensive knowledge of chemistry to take into consideration the weight, timing and density of mixtures, and thus, obtaining a perfect result of tone and saturation.

The factory kept as well some incoming letters in which the material providers deliver accurate instructions to develop dyes. For instance, a letter explains how solid blue B must be applied, with a printed sample appended.

Over the late 19th and early 20th centuries, LEI will usually use diamine, and synthetic dyes will gain ground to natural substances. Although we cannot quote the whole list of dyes used –most of them are listed on form 6110– the most commonly used were chloramine, toluylene orange, clorophenine, direct grey, metanilline, dianisidine, benzoazurine.

The discovery of new synthetic dyes contributed to change the world of fashion and home decoration. The 19th century would end with a wide spectrum of dyes of all tones; many of the natural variants will almost completely disappear. The 20th century will bring new breakthroughs on the history of dyes. In 1901 René Bohn patents idanthrene blue, the first synthetic anthraquinone dye, featuring some excellent washing and sunlight fastness. The copious discoveries to come will cast away the use of natural dyes, with some minor exceptions.

On document MEP 7063 from the early 20th century, we find a long list of new dyes, namely: naphthene, rhodamine, nitrazol, diamine, primuline, diphenyl, chloropherine, chrisamin, oxymin, rosophenine, chlorantine, benzoaurine, toluylene and thiophenol, among others.

The most important dye providers are Geigy, Leonart, Meister Lucius, Clayton, Casella, BASF, J. Bale, Thibaudier, Monegal, Riera, Bayer, V. Vidal, Kirchofer and Sandoz, some of the most outstanding and relevant chemical companies on the textile printing industry. Although most dyes are purchased outside Spain, Catalan experts as Josep Tay, Carles Casanoves and Manuel Solé are also mentioned and employed.

Since there is a direct relation between the fabric and the print to be applied, every kind of textile will require a different dye. This is why in the 20th century more dyes will be developed, mainly to colour new kinds of fabrics: polyester, rayon, polyamid and viscose.

This is the first study disclosing unpublished objects and documentation from the Museum, a series of scientific knowledge data and internal communications. With this documentation at hand we have been able to obtain a deep understanding of how dyes were used in the factory and trace them along a timeline, a sequence that has been compared with other printing manufacturers in Europe. The Museu de l'Estampació de Premià de Mar puts its collection to the disposition of researchers and experts wishing to investigate and study this historic period of industrial development. Additionally, the Museum preserves an extensive collection of dye catalogues dating from the 20th century from the main European factories, allowing establishing a bridge between both periods of time.

THE CONGRESSES OF RUSSIAN NATURALISTS AND PHYSICIANS AND THE MAKING OF ACADEMIC COMMUNITIES IN THE RUSSIAN EMPIRE, THE 1860S-1910S[1]

Marina LOSKUTOVA
Institute for the History of Science and Technology, Russian Academy of Sciences –St. Petersburg Branch, RUSSIA
mvlosk@yandex.ru

Abstract

In the 19th century academic congresses, both national and international, became critical institutional means facilitating the traffic of knowledge. Since the 'Great Reforms' era scholars in the Russian empire set up two major periodic conventions –the Russian archaeological congresses and the congresses of Russian naturalists and physicians– that served as important sites of academic socialisation and exchange of knowledge. In the early years of the 20th century they were supplemented by a few minor conferences on applied geology, meteorology and applied entomology. The paper examines changing institutional affiliation of congress members (both scholars presenting their papers and their audience) and their places of residence, as these transformations reflected the changing understanding of 'professional' and 'amateur' research, and the rise of professional middle-class strata in the provinces. It compares these processes across a number of disciplinary fields (life sciences, earth sciences, proto-social sciences), thus highlighting different roles played by university faculty, civil servants and professionals, major academic centres and provincial societies in structuring these fields of knowledge. Also the paper compares geographical configuration of emerging academic networks, exploring the impact of various regions and regional centres of research and education within the Russian empire. Finally, the paper examines the historical geography of congresses: it addresses the role of local field sites, leading local practitioners and provincial institutions in attracting the congresses to different urban locations, and considers the reception of congresses in local civic and intellectual context.

[1] The paper is based on research undertaken as a part of a project 'The making of fundamental biological research in Russia: institutional framework, funding, results, 1860s-1920s' funded by the Russian Foundation for Basic Research (ref. no.10-06-00093a).

In the 19th century academic congresses became important institutional means facilitating the traffic of knowledge and the making of academic communities and networks. National academic congresses, which emerged in Western Europe after the Napoleonic Wars, were a part of a broader trend towards institutionalisation of science at a national level. They were instrumental for the making of new disciplinary fields, expanding its audience, enhancing prestige of scholars, and linking the 'centre' and 'periphery' of science –provincial societies and major universities, amateur enthusiasts and established academics (On academic congresses in the 19th century Europe see: Fox, 1980; Casalena, 2006, Casalena, 2007; Withers, Higgit and Finnegan, 2008). The paper examines the congresses of Russian naturalists and physicians –a major academic forum for natural sciences that was established in the Russian empire in the late 1860s and convened periodically until the outbreak of World War I. It analyses a changing composition of the congress audience aiming to explore the relations between the university faculty and a broader public in a period when universities were unanimously considered as the major 'carrier' of science and scholarship in the Russian empire (Bastrakova, 2007).

Like many other academic institutions, national (or rather empire-wide) congresses were established in the Russian empire with some delay, when compared to Western Europe. In Russia they were a product of the 'Great Reforms era' of the 1860s –the decade of major political, social and economic reforms, epitomised by the abolition of serfdom in 1861. The idea to set up periodic conventions of naturalists was first conceived by Professor Karl Kessler (1815-1881) in the late 1850s. In the 1860s he emerged as one of the principle advocates and lobbyists of the congresses. The Ministry of Education eventually succumbed to his and his colleagues' entreaties and authorised the first congress of Russian naturalists to be convened in the late December 1867 - early January 1868 in St. Petersburg. The St. Petersburg University, where Kessler served as Professor of Zoology, hosted the event (Pogozhev, 1887; Tikhonovich, 1953).

Until the very end of the imperial period the congresses of Russian naturalists were run by the universities with financial support provided principally by the Ministry of Education. The Ministry encouraged the university and other higher school faculty members, as well as secondary school teachers to attend the congresses by authorising paid leaves for those employees who wished to attend the event. Yet the access was not restricted to these two categories: anyone who paid a small conference fee could sign up as a registered participant. Indeed, from the very first convention the congresses attracted substantial number of people with no recent connection to universities. Already the early congresses, which took place in St. Petersburg and Moscow in the late 1860s, drew several hundred participants. In the next decade, as the congresses moved to Kiev (1871), Kazan' (1873) and Warsaw (1876), the number of attendants perceptibly declined; however the return of the 6th congress to St. Petersburg in 1879 was marked by a dramatic increase of its audience. The growth continued in the 1880s-1910s, although each time a congress was held outside of the two capitals -in Odessa (1883), Kiev (1898) or Tiflis (Tbilisi, 1913)- the numbers dropped down again. By the early years of the 20th century the congress audience reached mammoth proportions, exceeding five thousand members.

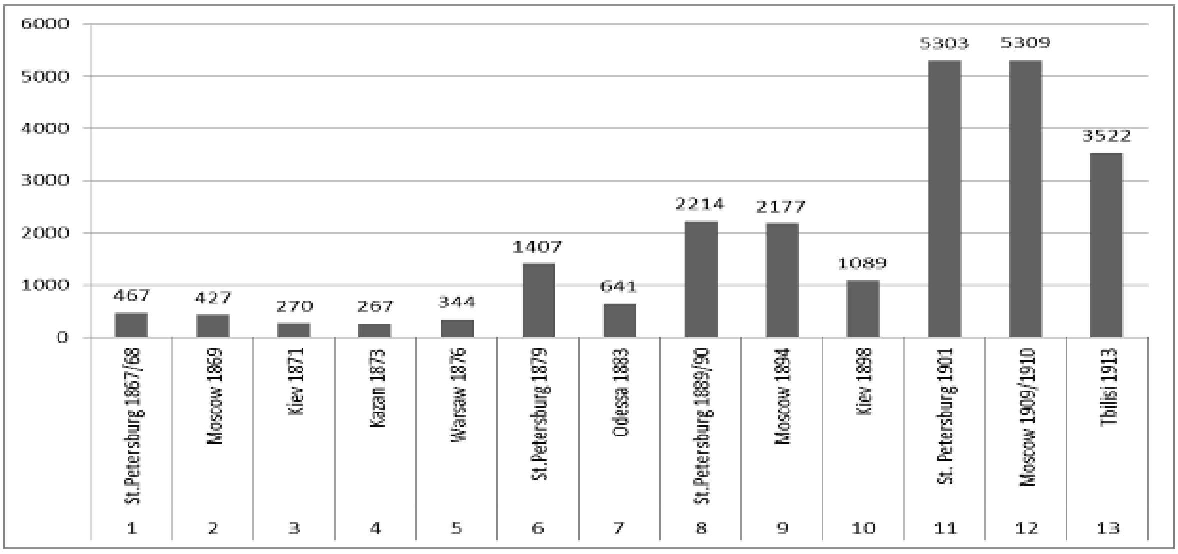

Fig. 1: Number of registered participants at the Congresses of Russian naturalists.[2]

[2] Sources: *Trudy pervogo s''ezda*, 1868, pp. xv-xxxiv; *Vtoroi s''ezd*, 1869, pp.1-21; *Trudy tret'ego s''ezda*, 1873, pp. 11-23; *Spisok chlenov IV s''ezda*, 1873; *Trudy V s''ezda*, 1877, pp. 4-16; *Rechi i protokoly VI s''ezda*, 1880, pp. 1-33; *VIII s''ezd*, 1890, pp. iv-xxx; *Dnevnik IX s''ezda*, 1894, no. 1, pp. 22-55, no. 3, pp. 15-24, no. 5, pp. 23-32, no. 10, pp. 52-62; *Vysochaishe utverzhdennyi X s''ezd*, 1898; Tikhonovich, 1953.

No doubt, the vast majority of the participants never visited more than just one congress. Of about 2,580 people who attended the first six conventions, only about 420 (or 16%) returned to take part in another congress. Later the ratio remained essentially unchanged: by 1898 no less than 7,400 people attended the congresses of Russian naturalists (the actual figure must have been even bigger, as no data exist on the participants of the 7th congress), yet it was only about 1,260 members (or 17%) who visited more than one convention.

Unfortunately, the data available on professional or institutional background of registered participants are not quite satisfactory, however there are some indicators suggesting that the university and higher school faculty composed about one quarter of the audience at the early congresses and their share remained relatively stable in the course of time, experiencing perhaps some decline at the 6th congress in 1879 but recovering by the last years of the 19th century. Another relatively stable group was formed by professional educators (mostly teachers at men's secondary schools run by the Ministry of Education) –they composed about 15-20% of all registered participants. Finally, already in the late 1860s-1870s a substantial part of the audience consisted of physicians, dentists, pharmacists and veterinary specialists. The medics became particularly visible at the 6th congress, when their share exceeded 30%. Indeed, we may assume that the first upsurge in the number of participants that took place at the same congress was at least partially accounted by a growing presence of specialists in various branches of medicine.

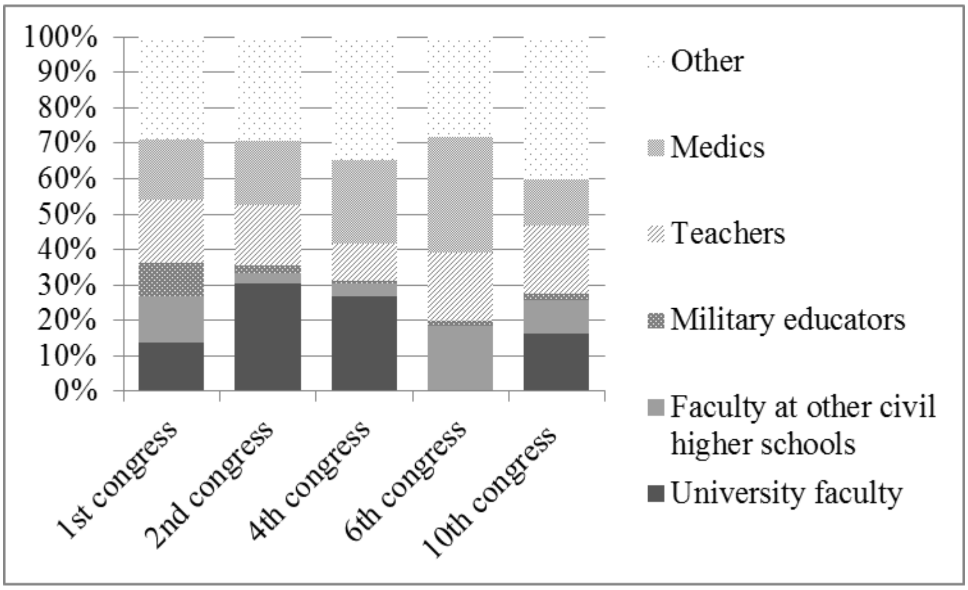

Fig. 2: Congress participants by occupation or institutional affiliation.

The audience of the first two congresses was exclusively male: it was only at the 3rd congress (Kiev, 1871) when the very first (and the only) woman showed up at the convention. Her name was Anna Volkova, she arrived from St. Petersburg and signed up for the chemistry section giving no details concerning her occupation or institutional affiliation. Volkova opened the way for other women: a few more attended the next congress in Kazan' in 1873. Yet at the Warsaw congress (1876) their number dropped down again to just two ladies. It was only at the 6th congress at St. Petersburg in 1879 when they began to form a sizable group (61 female participants on the list); even if proportionally their increase did not match the enlargement of the congress audience in general. A real growth occurred later, at the 8th congress (St. Petersburg 1889-90): the number of female participants increased more than three-fold, while their share among the audience grew up from 4.3 to 9.6%. The next congress in Moscow (1894) confirmed their increasing visibility, yet the move to Kiev, where the 10th congress took place in 1898, apparently discouraged women more than men from taking part in the event: not only the overall number of participants fell down twice, but also the proportion of women among them decreased to 5.1%. Quite predictably, the women who attended the congresses of Russian naturalists gravitated towards 'softer' subjects, such as geography and anthropology, while they were underrepresented at the sections on physics, mathematics and chemistry. Like in many other countries their role was initially rather passive: the very first woman who did not only attend a meeting but presented her paper and chaired a session at the 6th congress was Sofia Pereiaslavtseva (1851-1903), a graduate of Zurich University who would later earn an international reputation in marine zoology (On her see Mitrofanova, 1905). At the 9th congress in Moscow one more woman ventured to address the meeting as a speaker: this time she was Maria Pavlova (1854-1938), a graduate of Sorbonne, the wife of the leading Russian geologist Aleksei Pavlov, and a future prominent Russian palaeontologist on her own right (Borisiak, Menner, 1939). Yet even fifteen years later, at the 12th congress in Moscow (1909-10) there were just ten women among 478 speakers. (*Dnevniki XII s''ezda,* 1910).

The opening of the Russian naturalists' congresses for female speakers and audience could be seen as rather belated and slow, yet it was quite comparable with the advances in other areas of public scholarship in the Russian empire. Indeed, one way to assess the changing composition of the congress audience is to compare it to the public, who attended similar conventions for humanities –the Russian archaeological congresses. These meetings started in the same period (the 1st archaeological congress took place in Moscow in 1869) and met even more regularly than the naturalists' congresses until 1911. For the very first time women showed up at the 5th archaeological congress (Tiflis, 1881), i.e. even later than it was the case with naturalists, and with the course of time their visibility at the archaeological congresses (measured by their proportion to the congress audience as a whole) remained quite comparable with the situation at the naturalists' conventions (*Trudy V arkheologicheskogo s"ezda*, 1887, vol. 1, pp. xi-xii; *Trudy VI arkheologicheskogo s"ezda*, 1886, vol. 1, p. liii-lxii; *Trudy XIV arkheologicheskogo s"ezda*, 1911, vol. 3, pp. 32-42 pagination).

The fact that the naturalists' congresses were organised by the universities determined the choice of their venue: except the very last meeting (Tiflis 1913) all previous assemblies took place in the university centres of the empire. Predictably, St. Petersburg, as the imperial capital, hosted the largest number of conventions (1867-68, 1879, 1889-90, 1901), it was followed by Moscow (1869, 1894, 1909-10); twice the congresses met in Kiev (1871 and 1898), once in Kazan' (1873), Warsaw (1876) and Odessa (1883). In this respect the naturalists' conventions differed from the Russian archaeological congresses. The archaeological congresses also originated in the two capitals of the empire: the first one convened in Moscow (1869), the second one in St. Petersburg (1871), then followed the meetings in Kiev (1874), and Kazan' (1877). Later on the archaeological congresses occasionally returned to the university seats (Odessa in 1884, Moscow in 1890, Kiev in 1899, Khar'kov in 1902). However from the 1880s their geography rapidly expanded to encompass Tiflis (1881), Iaroslavl' (1887), Wilna (Vilnius, 1893), Riga (1898), Ekaterinoslav (Dnepropetrovsk, 1905), Chernigov (1908) and Novgorod (1911) (Lebedev, 1992, pp. 100-101).

Much wider geography of the archaeologists' conventions can be accounted by the fact that they were much smaller events (even in the 1910s the number of their participants did not exceed three hundred people) run by the Moscow Archaeological Society -an independent public association, very loosely tied to the university milieu. Another factor might have been at play as well: at least from the 1890s the choice of location for archaeological congresses was very much determined by the advancement of field research in a particular region. Potential interest, which a city could generate with its archaeological monuments and excavation sites, played an important role when the venue for a next convention was decided upon (Lebedev, 1992, pp. 100-101). As for the congresses of Russian naturalists, apparently, their organisers were most eager to show laboratories and museum collections. Characteristically, when congress participants had to vote for the location of the next naturalists' convention, the sections on chemistry or mathematics tended to favour St. Petersburg, while botanists and zoologists were more inclined to support the idea of changing the location (*Trudy V s"ezda*, 1877, pp. 66-68; *Rechi i protokoly VI s"ezda*, 1880, pp. 281 1st pagination, 26, 74, 123-124, 169, 238 2nd pagination).

The choice of the venue had serious implications for the composition of the congress audience. For obvious reasons the majority always came from the very city which hosted the convention. Since all the congresses of Russian naturalists and physicians, except the very last one (Tiflis, 1913), convened in the university centres, it reinforced the university domination not only in academic research and education but in the sphere of public science as well. Indeed, among non-local residents quite a number of people arrived to the congresses from the two capitals of the empire and a few other university cities. Nevertheless, there was always a sizable group among the audience, who resided outside of these major centres of scholarship, in the provinces. Naturally, the location of a particular congress was an important factor: these events always functioned as a powerful magnet for a much broader region outside the city where the meeting took place.

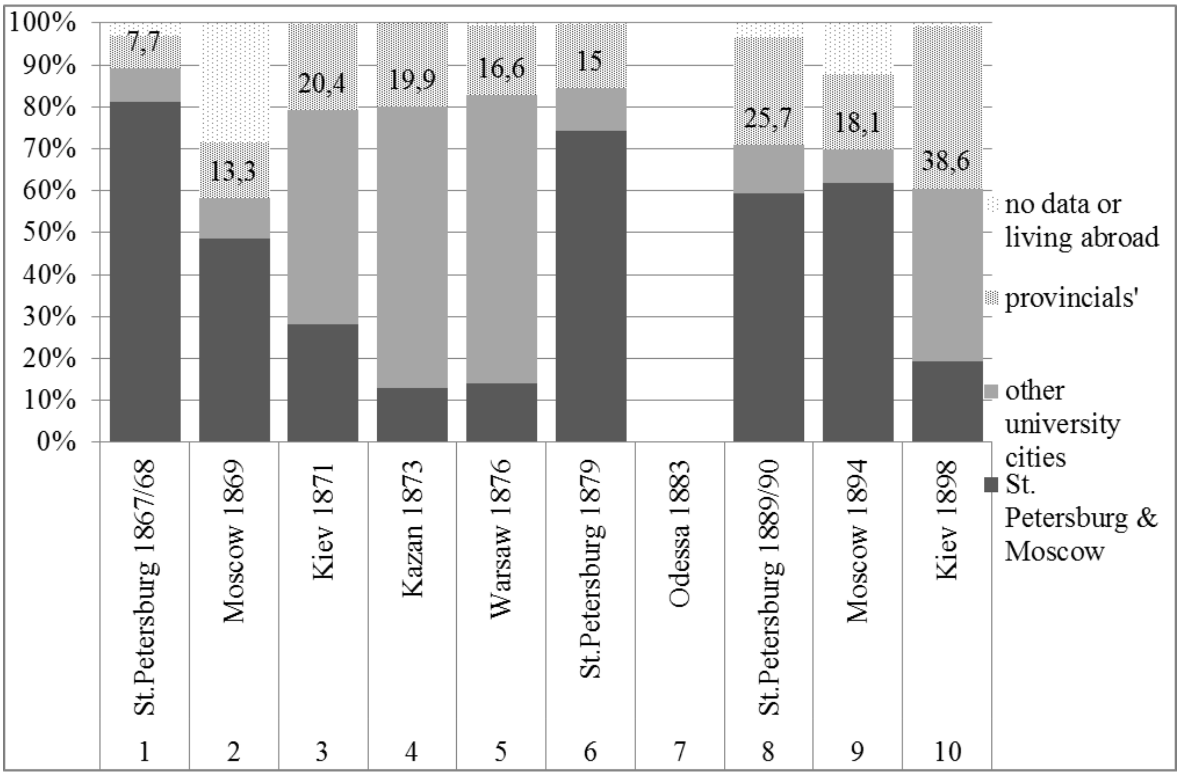

Fig. 3: Congress participants by place of residence.

Overall, there are some indicators that by the late 1890s the share of provincials among the public was on increase. Perhaps even of a greater importance was a steady albeit uneven expansion of interest in the congresses expressed by professionals and members of general public from a geographic perspective. Compare, for example, the two congresses, which took place in Kiev with the time gap of almost thirty years in between them. Among the participants of the 3rd congress less than thirty people lived outside of the capitals, university cities and provincial administrative centres, while the list of geographic names referring to their places of residence consisted of fifty entries. At the 10th congress there were no less than 415 provincials, while the same list contained 224 entries.

A substantial increase of the audience was paralleled by the expansion of the disciplinary field. Apart from plenary meetings, the program of the 1st congress encompassed subjects, which had already been institutionalized as independent chairs at the universities of the Russian empire, such as mathematics and astronomy; physics and chemistry (this section would be split into two different panels from the second congress onwards); botany; zoology; anatomy and physiology; geology and mineralogy. Sections for medicine and for technology were established at the 2nd congress. From the 3rd congress at Kiev (1871) the physics section encompassed physical geography, while the section on geology and mineralogy included palaeontology. A separate section on anthropology was established at the 4th congress (Kazan' 1873); later, at the 6th congress it was transformed into a section on geography, anthropology and ethnography. At the 8th congress (St. Petersburg 1889-90) new sections on 'scientific hygiene' and agronomy (plus veterinary) were added to the list. At the 9th congress (Moscow 1894) a subsection on statistics was established as a part of a broader unit for geography, anthropology and ethnography, while the 10th congress (Kiev 1898) provided space for separate subsections on meteorology and aeronautics.

Most of these disciplines had been to some extent reflected in the university curricula, or were in the process of their institutionalization as independent university chairs. However such sections as scientific hygiene, statistics, agronomy or anthropology had much broader appeal, as it can be demonstrated by a careful analysis of their audience. Indeed, the proportion of provincials who signed up for the sections on agronomy or statistics at the 10th congress was perceptibly larger than the proportion of provincials at the congress as a whole, while the share of provincials interested in botany, on the contrary, decreased and was smaller than the proportion of provincials at the congress as a whole.

Table 1: 'Provincials' at the congresses of Russian naturalists, by sections.

	3rd congress, Kiev 1871	10th congress, Kiev 1898
Life sciences (botany, zoology, anatomy and physiology)	31.3%	27.6%
Geology and mineralogy	35.3%	33.7%
Agronomy	-	64.2%
Statistics	-	57.4%
Medicine	9.1%	22.8%
Congress audience as a whole	20.4%	38.1%

A more detailed analysis of the botany and agronomy sections highlights a few more interesting trends concerning the institutionalization of these disciplines and the making of academic communities in the Russian empire.

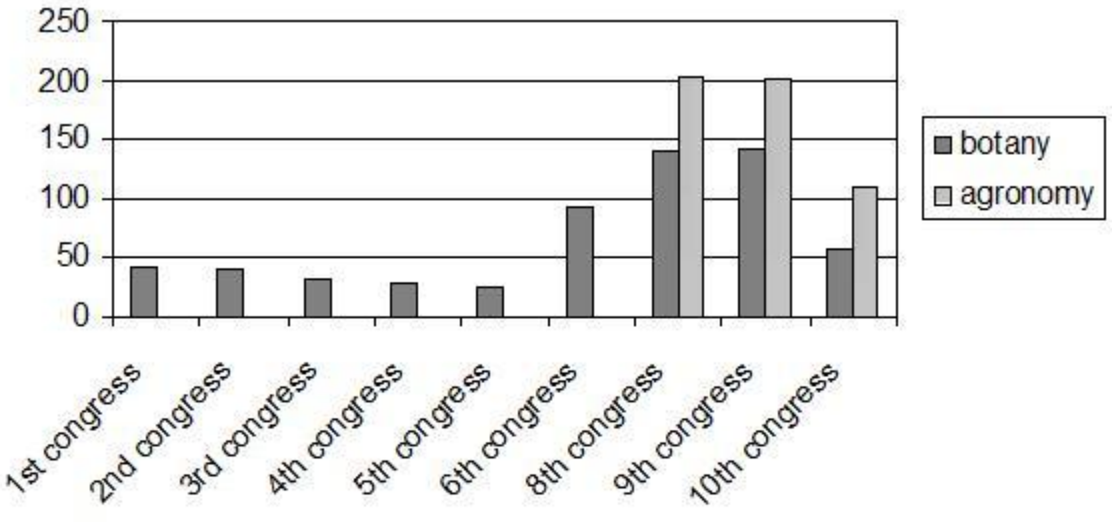

Fig. 4: Number of participants at the botany and agronomy sections.

The botany section was established already at the very first congress. The growth of its membership corresponded to the increase of the congresses' audience in general. Unlike the section on zoology, the botany section was heavily dominated by the faculty of St. Petersburg University, particularly at the early congresses, while it took quite a number of years for the faculty of Moscow University to get engaged in the events. The 'core' of the section was formed by a small group of people who missed very few conventions (2-3 out of 9), and who almost always presented a paper or chaired a session. All these men were the leading botanists from St. Petersburg -Andrei Famintsyn (1835-1918), Andrei Beketov (1825-1902), Ivan Borodin (1847-1930), Christopher Gobi (1847-1919) from the University, Aleksandr Batalin (1847-1896) from the Academy of Sciences, and Mikhail Voronin (1838-1903), who for the most part of his career was an independent scholar but who graduated from St. Petersburg University and maintained close ties with the University and the Academy of Sciences. By contrast, the only faculty member of Moscow University who attended more than three congresses was Kliment Timiriazev (1843-1920). Characteristically, after the first congress (where he was present) he failed to show up at these meetings until 1879, missing four conventions in a row.

The agronomy section, on the contrary, was established only at the 8th congress at St. Petersburg in 1889-90. From the start it attracted many more people than the botany section, and the proportion of provincials was much higher. Its audience proved to be not particularly stable, yet there was a small group of people who attended all three congresses (the 8th, 9th and 10th), for which we have data. Only one of them, Nikolai Adamov (1861-1912), was a member of the St. Petersburg University faculty; however in the 1890s he was still at the early stage of his career, serving as a custodian of the agronomy research room at the University. The two others, Aleksandr Kliucharev (1866-1932) and Aleksei Fortunatov (1856-1925) had established themselves at the Moscow Agricultural Academy. By the late 1890s, however, Fortunatov would move to New Alexandria (Pulawy) in Russian Poland. The Institute for Agriculture at New Alexandria that employed Fortunatov provided institutional affiliation for another member of the same group –Nikolai Sibirtsev (1860-1900). Sibirtsev began his academic career in 1882, when he took part in a famous soil survey of the Nizhnii Novgorod province, led by his mentor, Vasilii Dokuchaev (1846-1903). After the completion of the survey Sibirtsev remained in Nizhnii Novgorod for a few more years, taking up a position at a local museum of natural history. In 1892 he briefly returned to St. Petersburg, took part in another expedition headed by Dokuchaev, and then moved to New Alexandria, where Dokuchaev had already been serving as the director. The other three members of the 'core group' at the agronomy section were provincials –teachers or agronomists.

The same conclusion is applicable to a larger, much more volatile part of the audience: unlike botanists, very few members of the agronomy section had a university affiliation: those who taught at higher schools were employed either by the Moscow Agricultural Academy, or (less frequently) by the Institute for Agriculture at New Alexandria. While secondary school teachers were equally prominent at both panels, a substantial part of the audience on the agronomy section was composed by practicing agronomists, statisticians, and veterinary specialists.

This observation supports an argument recently advanced by some scholars who work on the history of various disciplines in the late imperial Russia. Apparently, by the turn of the 19th - early 20th century new fields of knowledge were emerging outside of the university framework. These new disciplines, like physical anthropology or plant breeding, challenged established academic hierarchies: they were much more committed to the idea of public science being more open to amateurs or practicing professionals, and pursing objectives, which were explicitly connected to immediate social problems. (Cf. Elina, 2008, vol.1, pp. 310-334; Mogilner, 2008, pp. 39-53, 162). The rise of these disciplines signalled the end of an epoch when the universities were the leading segment of research institutions in the Russian empire.

Certainly, further study is needed to understand behind-the-stage mechanisms, which determined the inclusion and exclusion of certain figures, institutions, social and professional groups in/from the congress network. We need to know more about formal and informal ways in which speakers and their audiences were recruited, and decisions were made to establish new sections. What is clear at the moment is that in the late 1860s-1880s the university faculty played the dominant role in the congresses providing the key speakers, while the most visible groups among the public were secondary school teachers and doctors. By the 1890s-1900s, as the audience expanded dramatically and new disciplines were introduced into the program, the conventions of Russian naturalists and physicians began to attract a very different social stratum of professional people, experts in applied disciplines, such as agronomy, veterinary, forestry, and statistics. These people, who often lived and worked outside of the university centres, were instrumental for the dissemination and popularisation of science in the Russian empire in the early decades of the 20th century.

THE INTERNATIONAL CONGRESS OF ELECTRICIANS OF PARIS AT 1881 AND ITS CONSEQUENCES IN COIMBRA

Susana BOLOTO, Décio R. MARTINS

Faculty of Sciences and Technology, Universidade de Coimbra, PORTUGAL
susanaboloto@hotmail.com

Abstract

We analyze the repercussions in Portugal of the International Congress of Electricians, held in Paris in 1881, which was attended by the Portuguese representative, Professor of Physics, António dos Santos Viegas. We focus on the analysis of the motivations underlying its realization and the impact of its resolutions on the development of Physics at the University of Coimbra, since the Portuguese representative in this Congress was professor of physics at this institution for more than 50 years.

Portugal in the International Congresses of unit systems

In 1852 Queen Maria II adopted the decimal metric system, already introduced in France in 1791, establishing a stated period of 10 years for its general application. Simultaneously it was created in the Ministry of Public Works, Commerce and Industry, the Central Commission of Weights and Measures. In 1855 it was created the General Inspection of the Weights and Measures of the Kingdom, having been its first General Inspector, *Joaquim Henrique Fradesso da Silveira* (1825-1875), professor of Physics and Chemistry of the Polytechnic School of Lisbon. In 1859 he published the Compendium of the Metric System, which helped to implement this system in the country.

The *Convention du Mètre* was signed on 20th of May 1875 by 17 countries. Portugal was represented by the plenipotentiary minister in Paris, Jose de Silva Mendes Leal (1820-1886). This Commission aimed to establish an international authority in the metrology field, responsible for the development and safeguard of the measurement standards. Mendes Leal, who was also the Portuguese Commissioner in the Universal Exposition of 1878, had an important role in the negotiation of the Telegraphic Convention between Portugal, Spain and France, signed in Paris in 1880.

The International Congress of Electricians held in Paris in 1881 was the first step for an important series of accomplishments of international level. Between 15th September and 5th October, this meeting gave official and international recognition to the proposals of the British Association for the electric units Volt and Ohm, and added the Ampere, Coulomb and Farad to the two previous units. [1]. Later on, in the Congress of Chicago (1893), the nine electromagnetic units were adopted in successive steps: the Ohm, Volt, Ampere, Farad, Coulomb, Joule, Watt, Henry and Weber. In 1933, Giovanni Giorgi (1871-1950) displayed the system that he already had presented in 1901, in Rome, which had as basic units the meter, the kilogram and the second –the MKS system– that should be applied in 1940 for deliberation of the *International*

Electrotechnical Commission (IEC), but that this only happened eight years later. This system was called *International System* in 1960.

The International Congress of Electricians of 1881

Scientists and telegraphers congregated in Paris in 1881 (Figure 1), under the sponsorship of the French *Ministère des Postes et des Télégraphes*, recognized the necessity to fix electric units, so that all the measures were comparable in all countries. The choice of a French city became obvious because France played a central role in the international metrology based in the creation of the metric system and in the presence, in the city of Paris, of the *Bureau International des Poids et Mesures*.

Fig. 1: *Comptes rendus des travaux* of the International Congress of Electricians of 1881.

This congress had a strong contribution of the Telegraphic Engineers. The Telegraph Engineers Society had been established on 17th May 1871, in a meeting in Westminster - Victoria Street, London, and Charles William Siemens (1823-1883) had been invited to be its first president. On 22nd of December 1880, this British institution started to be named *Society of Telegraph and of Electricians*. Alexander Trotter Pelham (1857-1947), who joined the institution in 1885, thinks that the term "electric engineering" started to be used in the exposition of Paris in 1881. On 10th November 1887, the previous Society of Telegraph Engineers received the name of *Institution of Electrical Engineers*. Nowadays it is known as *Institution of Engineering and Technology*, currently the second biggest institution of engineering of the world.

The Congress established the definitions of the following physics units: Ohm, Volt, Ampere, Coulomb and Farad, but they could not obtain the definition of the unit of force that, not being considered basic, had also to be defined in the scope of the electricity. A proposal was also made to a definition of a luminous unit and an adjusted standard was chosen to measure the intensity of light.

In the last day of the Congress, on 5th October, the Permanent Secretary of the Academy of Sciences, Jean Baptiste Dumas (1800-1884) a French chemist, dedicated his speech to the conquests of the *British Association*, standing out that the vast industry based on the electric power (…), could only effectively progress if the measures used by several countries were standardized [2]. So, we can affirm that the Congress of the Electricians in Paris emerges as one of the most excellent examples of the globalization of science.

Three goals were reached with this event: the normalization of the electric units, the presentation of important works in the scope of terrestrial magnetism, meteorology and telecommunications and the conscience by electricians of the necessity of interfaces that bound electric installations between them. In this Congress the presence of German, Belgian and even British members was very strong including also the French. From Portugal, the plenipotentiary minister in Paris was invited as a extraordinary guest, as well as the Honorary State Minister and Pair of the Kingdom of Portugal, João Andrade Corvo (1824-1890), the Council Guilhermino Augusto de Barros (1835-1900), general Director of the Post Offices, Telegraphs and Lighthouses of the Kingdom of Portugal, and also António dos Santos Viegas (1836-1914), professor of Physics at the University of Coimbra, UC, and its rector twice [3]. Barros would become an important figure because he had a preponderant role in the concession contract with *Edison Gower Bell* on 13thJanuary 1882, that gave this company the opportunity to install all the telephonic stations in Lisbon, Oporto and other suburban areas.

Fig. 2: António dos Santos Viegas, professor of Physics at the University of Coimbra.

The 2nd session of the Congress, on 17th September, congregated the discussion about globe's physics, terrestrial magnetism and atmospheric electricity, under the presidency of Dumas. The Director of the Magnetic Observatory of the UC, Santos Viegas (Figure 2), affirmed that this institution used the methods of Gauss with the modifications introduced by the German physicist Johann von Lamont (1805-1879) and the instruments recommended for the Kew Observatory. He considered, as a starting point for an international standardization, that two things should be determined: the nature of the observed phenomena and the possibility to choose standard instruments to be used in the observations. After some interventions, Éleuthère Mascart (1837-1908) read the final resolutions that seated on the measures that would have to be made by some telegraphic administrations in order to organize a systematic study of terrestrial electricity. It was considered that those measures should be collected under an International Committee, and in the impossibility to get this organization it would be desirable that, at least, the observations were made in specific days chosen by the International Commission of the Polar Year established in 1879.

This Commission was in charge of using the observation methods for the atmospheric electricity with the intention of generalizing the study of the terrestrial surface. These resolutions suggested that Santos Viegas' intervention was an important contribution in the systematization of the studies related to Earth Sciences. The Commission integrated different country representations: Denmark, Norway, Russia, Sweden, Finland, Germany, the Austro-Hungarian Empire, the Netherlands, France, the United States and Great-Britain, with the support of the new Domain of Canada. It also established that the first International Polar Year would be carried through in 1882-1883, to coincide with a transit of Venus foreseen for day 6th of December 1882.

Resolutions of the Electricians Congress of 1881 in the UC and its Repercussions

The Congress of Paris of 1881 had strong repercussions in the development of Physics in the UC. António dos Santos Viegas was, after the Congress, one of the founders of the *Société Internationale des Electriciens*, renamed later on *Société Française des Electriciens*. During the second half of the 19th century, the international contacts made by Santos Viegas, Professor of Physics for more than 50 years, had been fundamental for the development of the scientific instruments collections of the Physics Department and the Meteorological and Magnetic Observatory of the UC. In 1883 he was member of the Scientific Commission of the International Exposition of Electric Engineering, in Vienna, led by Jozef Stefan (1835-1893), director of the Institute of Physics of Vienna. In his visits to France, Belgium, England, Scotland, Germany, Austria, Italy, among other countries, Viegas knew and worked with many famous scientists such as Bourbouze, Bianchi, Jamin, Verdet, Cornu, Regnault, Secchi, Thomson, Koenig, Helmholtz or Kirchhoff.

At the *Conservatoire des Arts et Métiers*, Viegas also knew Alexandre Edmond Becquerel (1820-1891), Henri Becquerel's father (1852-1908) who discovered radioactivity. Under his influence, teaching experimental Physics at UC become very similar to French schools and being much close to the *École Polytechnique* of Paris. Santos Viegas' supervision allowed the instruments collection at the Physics Department to be continuously updated. In its vast collection there were several instruments made by Duboscq and Pellin, Hardy, Salleron, Deleuil, Ducretet, Carré, Breguet, Bianchi, Koenig, Ruhmkorff, Ernecke, Muller-Unkel, Geissler, Siemens & Halske, Casella, Kohl, among others.

Santos Viegas had much influence in the scientific panorama of the UC during the second half of the 19th century, mainly in the area of Physics. The subjects studied by his students were characterized by an excellent scientific actuality. Until the 60s, the theses defended in the Faculty of Philosophy, FPh, in Coimbra, a subject dealt with some relevance was meteorology, a fact that is related with the foundation of the Meteorological and Magnetic Observatory in 1864. From that point on, all subjects of academic papers had started giving importance to electromagnetism, such as the academic thesis of Adriano de Paiva Brandão (1847-1907), in 1868, as well as the ones of Henrique Teixeira Bastos (1861-1943) in 1884. Here we can notice an increasing interest for this subject, already evidencing the influence of the resolutions of the Congress of Paris. In 1897, in the António Vellado Pereira da Fonseca's theses (1873-1903), electromagnetism starts occupying a central place in the subjects studied. In this work Röntgen rays are also mentioned, which shows modern aspects in the physics syllabus in the FPh of the UC.

António Meirelles Garrido presented in 1878 a study on the Mathematic theory of propagation of light in a homogeneous environment [5], basing his study on the theory of mechanics' propagation of light. In 1879, Garrido presented another study: *the Radiometer*, in which he considered to make one brief summary of the facts established by the experience and to argue the value of different theories of radiometric movements [6].

Electric Units [7] was the theme of Henrique Teixeira Bastos' thesis in 1884. He was António Santos Viegas' disciple and this work could represent the first relevant influence of the Congress of Paris in 1881 on the Experimental Physics Department of the UC. In this study, the author displayed the system of electric units used by the time, dividing the book in three basic parts: Definition of the units, their comparison with the arbitrary units and their material representation. In the introduction, Teixeira Bastos made reference to the Congress of Paris of 1881, in which electric units would have been generalized. *Electromagnetic Theory of Light* (1885) was the subject of his dissertation for admission to university career [8].

In the sequence of the subsequent developments in electromagnetism, in 1897, Vellado Pereira da Fonseca studied electric oscillators [9]. This work was published in two parts: the first one refers to the optics of oscillations and the second one, which was a scientific study submitted to his admission to university career, he analyzed the effects of electric oscillations. The second half of this work had a more practical source. It talked about electric oscillations' potentialities used for illumination through the Tesla effect . Fonseca concluded his work with an entire chapter dedicated to wireless telegraphy, making reference to some wireless message transmission methods, based on electromagnetic radiations.

Anselmo Ferraz de Carvalho (1878-1955) presented academic theses, where we can see subjects related to electromagnetism, meteorology and X-rays. In 1901 he defended his scientific study on *Magneto-Optic Phenomena* in which he studied two different Physics' areas: electromagnetism and light [10]. He showed knowledge of recent works carried by other physicists in this area.

Beyond the academic theses, some scientific articles had been published in the scientific and literary magazine *O Instituto* (*IC*), published in Coimbra since 1852. Some different articles were related with electricity or electromagnetism, but some of them were distinguished by its relevance on electric telegraphy, as Jose Maria Abreu's articles [15].

At the end of the 70s new articles had started to appear in *IC* related with electromagnetism applications: Adriano de Paiva Brandão in 1878 and 1880 –*Telephony, telegraphy and telescopy* and *electric telescopy* [16]. In the 1878's article, Paiva argued about the advantages of Bell's telephone and its ability to transmit sound messages. He concluded that, in the future, we would obtain a technology based in photoconductive properties of selenium, discovered in 1876 by Werner Siemens (1816-1892), foreseeing the possibility to convert optical images into electric impulses that would be transmitted by telegraphic wires. Therefore, Paiva is considered a precursor of television [16]. Effectively, his successors only appeared some time later. English physicist Shelford Bidwell (1848-1909) published on 10th February 1881, the article entitled 'Tele-Photography' in *Nature*. About one month later, on 11th March, he presented to the London *Royal Institution* the communication on *Selenium and Its Applications to the Photophone and Telephotography*, coming back to the subject in the same magazine on 4th June 1908, with the article *Telegraphic Photography and Electric Vision*. A few days later, on 18th June, the Scottish Campbell Swinton (1863-1930) published an article in *Nature*, with the title *Distant Electric Vision*, in which he suggested the use of cathode rays to obtain images.

In 1903, Álvaro José da Silva Basto published six articles under the subject *Phenomenon and experimental disposals of wireless telegraphy* [17].

The first studies on radiation Physics in Coimbra

Henrique Teixeira Bastos also wrote some articles about the first experiences on X- Rays. In his article [18], he described the experiences made at the UC in January and February of 1896. The discovery of X rays originated an immediate scientific interest in Coimbra. Only about one month after the announcement of Röntgen's discovery, the first essays were made in the Cabinet of Physics of the UC, in contribution with the professors of the Faculty of Medicine, guided for its application in clinical diagnosis. It started a tradition of contributions between these two institutions that lasted until nowadays. A result of this was the creation of the Laboratory of Radiology of the Faculty of Medicine of the UC. In 1901, the decree nº 4 of 24th December, established the *Bases for the Reorganization of the University of Coimbra* and promulgated the creation of the Radioscopy and X-ray Department in the UC's Hospital.

In the experiments made by Bastos, a Ruhmkorff bobbin was excited by six electric batteries of Bunsen and an electrical discharge was produced in a Crookes tube, next to which was placed a photographic plate and on the top of it the experimental object, for about 20 minutes of exposition. He recognized that the obtained results were good; even so the experiences were delayed. At the time Teixeira Bastos could not foresee all the practical applications of this process. He just refers that it started to be used in UC Hospitals, more properly in the clinical diagnosis.

In the same year, in April, Teixeira Bastos published a new paper on the same subject [19] describing the recent works of Becquerel. He mentioned the *Scientific American* magazine of that same year, that explained the studies made in Edison's laboratory which showed that by using a new process, the human bones could be see using a fluoroscope, with bigger commodity for the observer. This technique was soon introduced in Coimbra.

Álvaro José da Silva Bastos (1873-1924) presented the academic thesis entitled *Cathodic Rays and X Rays of Röntgen* in May of 1897 [4]. In this work, the author mentioned the experiences which he carried out with electric discharges in gases, establishing the comparison between X rays and the rays of Becquerel, and analyzed several theories of the X rays' nature, describing several production and application techniques of these rays. In this work he presented references to some foreign publications, such as Perrigot's in April of 1897 in the Academy of Sciences of Paris published in the *Comptes Rendus*, Gustav Le Bon's publications in April of the same year, and Henri Becquerel's on 10th May. It equally showed a deep knowledge of the evolution technique and the experimental results concerning this subject.

In its appliance paperwork to teaching in the Polytechnic Academy of Oporto, entitled *Becquerel Rays and Polonium, Radium and Actinium* (1902), Alexander Alberto de Sousa Pinto (1880-1982), who had recently concluded his studies at the UC, recognized that the scientific development, subsequent to December 1895, promoted an impressive series of research on Becquerel Rays [11]. By that time this subject was considered extremely important by the international scientific community. There was a raised number of published works that Sousa Pinto had access to, little before printing his own dissertation. Some of the cited works are: Henri Becquerel's publications in the *Comptes Rendus* t. CXXXIII, 199 and 977 of 22nd July and 9th December 1901; Pierre Curie's publications in the same magazine in the t. CXXXVIV of 17th February 1902. In its final note, he gave special relevance to Madame Curie's work on the determination of radium's atomic weight published in the same magazine, t. CXXXV, p. 181, of July 1902; Hoffmann and Strauss' work about obtaining preparations of radioactive lead published in the magazine *Berichte Deutschen Chemical Gesell* of 18th January 1902 and in the *Chemical News* in February of the same year; denoting not only actuality, but also access to several works made by physicists all over the world.

The radioactivity subject continued to deserve some importance in the UC Physics Department. In 1906, João de Magalhães presented a thesis: *Radio and Radioactivity* [12]. In 1906 and 1907 he published eleven papers about this matter in *O Instituto* of Coimbra [13]. Francisco Martins de Souza Nazareth submitted, in 1915, the paperwork for his appliance to Second Assistant for UC's Faculty of Sciences which subject was: Ionization of gases in closed vases [14]; it was the first experimental work in Coimbra involving radioactivity detection.

Conclusion

In conclusion, the International Congress of the Electricians of Paris in 1881 changed everything and had an extreme impact on people's life, and brought some academic consequences in Portugal. Professors and investigators started to invest more in the study of electromagnetism, which allowed to the development of this science in teaching and/or research, or in its applications. The access to the information of what was happening in foreign countries, as well as the representation of the Faculty of Philosophy of UC in scientific congresses and other scientific events had influenced academic interests in knowledge areas such as electricity, magnetism and electromagnetism, specially in the 70s; that can be easily proved through published works.

Abstract

To understand the circulation of scientific knowledge and scientists in Europe in the 20th century it is essential to identify the institutions that attracted foreign scientists to all kinds of training. To construct such broad picture it would be compulsory to study the dissemination of scientific culture over Europe. To accomplish this, it would be necessary to assemble as many information as possible about specific institutions and scientists.
There are several analyses on the development of science, in particular European institutions and in specific disciplines, that referred the passage of foreign scientists to those places, as in Paris. However, this is not the main goal of the authors. Some work has been made on the history of Foundations where grants attributed can be studied, as for example the Rockefeller Institution. The institutions that manage and promote national science were also studied, and these played the principal role sending apprentices abroad. This is the case of the Spanish JAE, Junta de Ampliación de Estudios*.*
Currently, we study the Portuguese scientific apprentices in Europe and pretend to contribute to picture the scientific attractive institutions in the thirties and forties. We intend to show that, through time, there were geographical changes on those institutions at a particular discipline. We want to underline several factors influencing the selection of destinations and how these factors conditioned the circulation of scientists. The success, renown and visibility of an institution or scientist act together as a factor, but they are not by far the

1 This work is part of the Project "The Scientific Research in Portugal between two world wars and the organization of a National Board of Education" financed by: FEDER Funds as Operational Program of competitiveness factors (COMPETE) and by National Funds throught FCT project HC/0077/2009.

only one. In the Portuguese case we can identify other factors on different levels: the country's characteristics or constraints, the national institutions to where apprentices were connected, and the orientation of particular characters. However, besides all these factors we want to enhance the leading role of JEN (Portuguese Board of National Education) promoting scientific apprenticeships in Europe.

Introduction

The *Junta de Educação Nacional*, created in January 1929, was the first Portuguese organization intended to foment and manage the scientific investigation of the country. Despite the fact that JEN changed its name to "*Instituto para a Alta Cultura*" (IAC), in 1936, this institution kept all its former goals. JEN's main attributions were to organize Portuguese scientific work, to prepare technicians intending Portuguese economic improvement and to manage the dissemination of culture and intellectual interchanges. Its main action lines were to subsidize scientific institutions, to give grants to outstanding or promising investigators, and to promote the publicity of scientific products or results. JEN invested a big slice of its expenditure in grants, almost 50%.

The support to grant holders was intended to fulfil their professional education and attain their "framing" into the modern knowledge abroad as a way to improve their productivity. It was imperative to give them a broad picture about the scientific activities of other countries, for instance, stimulating their participation in Congresses. When a grant holder come back to Portugal after its formation, JEN was supposed to settle him in proper institutions or improve their former work conditions. Besides this grants to foreign countries, JEN also attributed grants to support works in Portugal. Usually the number of grants to foreign countries (roughly 32 per year) was greater than the grants to Portugal (near 23 per year). Grants to foreign countries constituted around 39% of JEN's total expenditure and national grants constituted nearly 10%.

At this paper we focus on JEN's science grant holders that undertook their apprenticeships at foreign countries, mainly in Europe, in the 1930s and 1940s. To study JEN grant holders that were spread on the international space we have turned to first-hand documents: JEN's reports, Proceedings of JEN's Executive Council, and grant holders' archive information. As international circulation of science was the central interest of the 4th ESHS Congress, we directed our analysis to the group of European places travelled by JEN Portuguese grant holders. We characterized these places considering their attractiveness to persons that intended to undertake an apprenticeship. Several factors could contribute to their attractiveness, but they were essentially related to the existence of outstanding professors or to well-based institutions.

Extending the study about science grant holders in Europe

Analysing the works of History of Science about grant holders we can see that they followed some different ways of analysis depending on the considered study objects. (1.) A great part of those works deals with academic itineraries of specific scientists or their professional groups. As an example we can point out some studies about the "*Junta de Ampliacion de Estudios*" (JAE) grant holders, from Spain: following JAE's 2007 centenary, Spanish historians of science published *Tiempos de investigación* about JAE activities, where they developed a particular chapter about Ramon y Cajal, Ignácio Bolivar and José Castillejo. They were men compromised at JAE's development and management. (2.) Other kind of grant holders' analysis focuses on the development of a specific scientific area at a country or region. For instance, this constitutes the major part of the book *Tiempos de investigación* (the one already referred above about Spanish JAE), as it presents different chapters about Pedagogy, Physics and Chemistry, Natural Sciences and the Botanical Garden, Philosophy, Archaeology, Biomedical science, Technology and Applied science, etc. These works are showing grant holders' preponderant role to the development of science, mainly in Spain. In another book, Yves Gingras' *Physics and the Rise of Scientific Research in Canada* (1991), its author studied the creation of Canada Physics Community and he emphasised grant holders' roles. (3.) There are some historical works studying a specific scientific institution, its actors and activities, mainly on local context. (4.) Others are studying the philanthropic foundations that supported scientific activities, both learning and investigation, as Rockefeller, Ford and Carnegie Foundations. The book by John Farley *To cast out disease: a history of the International Health Division of the Rockefeller Foundation (1913-1951)* (2004) is an example, but it didn't focus on grant holder's activities or enhance their importance to the international scientific movement. The book *Rockefeller and the internationalization of mathematics Between the Two World Wars* (2001) by Reinhard Siegmund-Schultze is focusing on Rockefellers' mathematics grant holders. Siegmund-Schultze refers to Rockefeller's scientific policy and its selection criteria regarding grant holders and institutions subsidized. Our present work has similar aspects to this Siegmund-Schultze book as analysing grant holders' selection process. However, there are differences between JEN and Rockefeller, for instance on their managing role and objectives, and of course, on the historical contexts beneath their grant's services. Siegmund-Schultze has focused on the thematic of internationalization of science, based on the scientific activity of Rockefeller's grant holders and subsidized institutions. At our present study we are taking for granted that grant holders have somehow participated at the international circulation of science. We have a different goal from Siegmund Schultze's book: we intend to exploit the information about grant holders' staging places to outline a geographic representation of the "Scientific Europe" and most importantly, a moving picture of the International Circulation of Science.

Changing science apprenticeship places

Analyzing the geographical destinations of JEN grant holders, its relation with the grant scientific area, and its variation over the time (1929-1938) we can identify some tendencies and thus endeavour some brief conclusions.

At first sight we can see that the number of JEN grant holders to foreign countries has geographically changed. It is important here to clarify that JEN never specified any annual number of grants destined for each country. The three most chosen countries to go abroad were France, Germany and England. Besides these, grant holders have gone to Switzerland, Italy, Belgium, Poland, Yugoslavia, Spain and the United States. Considering all the grants given to all the countries, France was the most chosen country, followed by Germany. If we consider only the average numbers, at France there were present 12 Portuguese grant holders per year and at Germany there were 11 of them. At England there were only 6 grant holders per year.

Some grants of a specific scientific discipline have been undertaken at the same staging places. So, selecting the staging places was certainly related with the scientific themes of the grants. At Physics, Chemistry, Mathematics and Astronomy, all together, Paris was the most chosen destination (49 grants out of a total 98, i.e. 50%). Generally, the stages on Engineering, Medicine and Biology were spent in Germany. Some places corresponded to just a scientific discipline, as Physics at Dahlem and Giessen (Germany), Medicine at Dublin (Ireland) and Stockholm (Sweden), Geology at Lille (France), Malariology at Skopje (Yugoslavia), etc. Three grant holders on Sciences of Animal and vegetable Production have made their training at the USA (California, Wisconsin, New York and Providence), and they were the only ones going there.

If we take a specific discipline, the staging places selected were not the same along time, as we can see in figure 1, considering Medicine (joining all medical practice, surgery and Biomedicine).

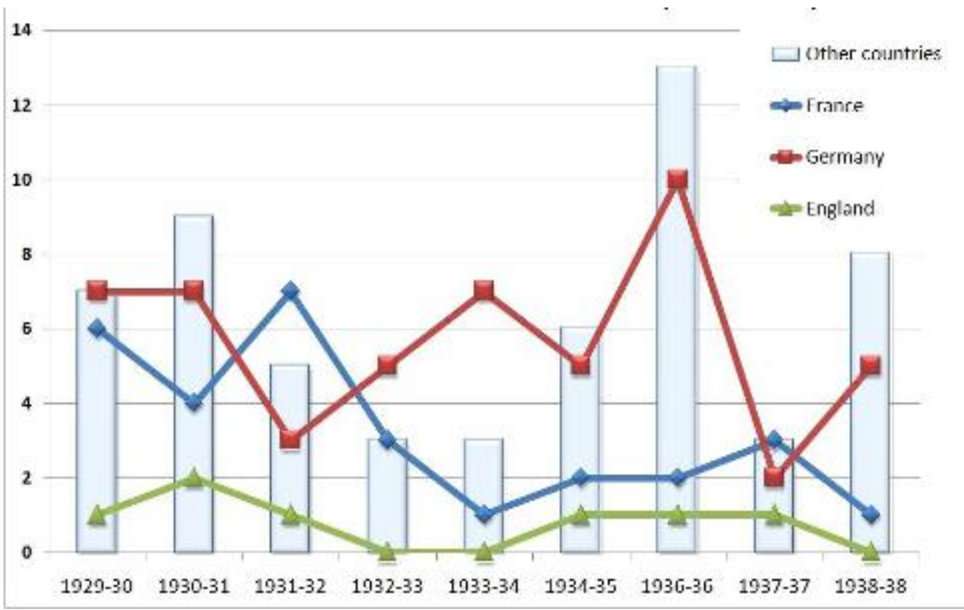

Fig. 1: Number of grants to Medicine (1929-1938).

From figure 1 we can see that in 1929-30 JEN' major number of grant holders was in Germany, and in 1931-32 they diminished there to rise in France. After 1933-34 most of grant holders were going to Germany again. At medicine there were always less grant holders at England than in other countries. We can display a similar analysis to other disciplines.

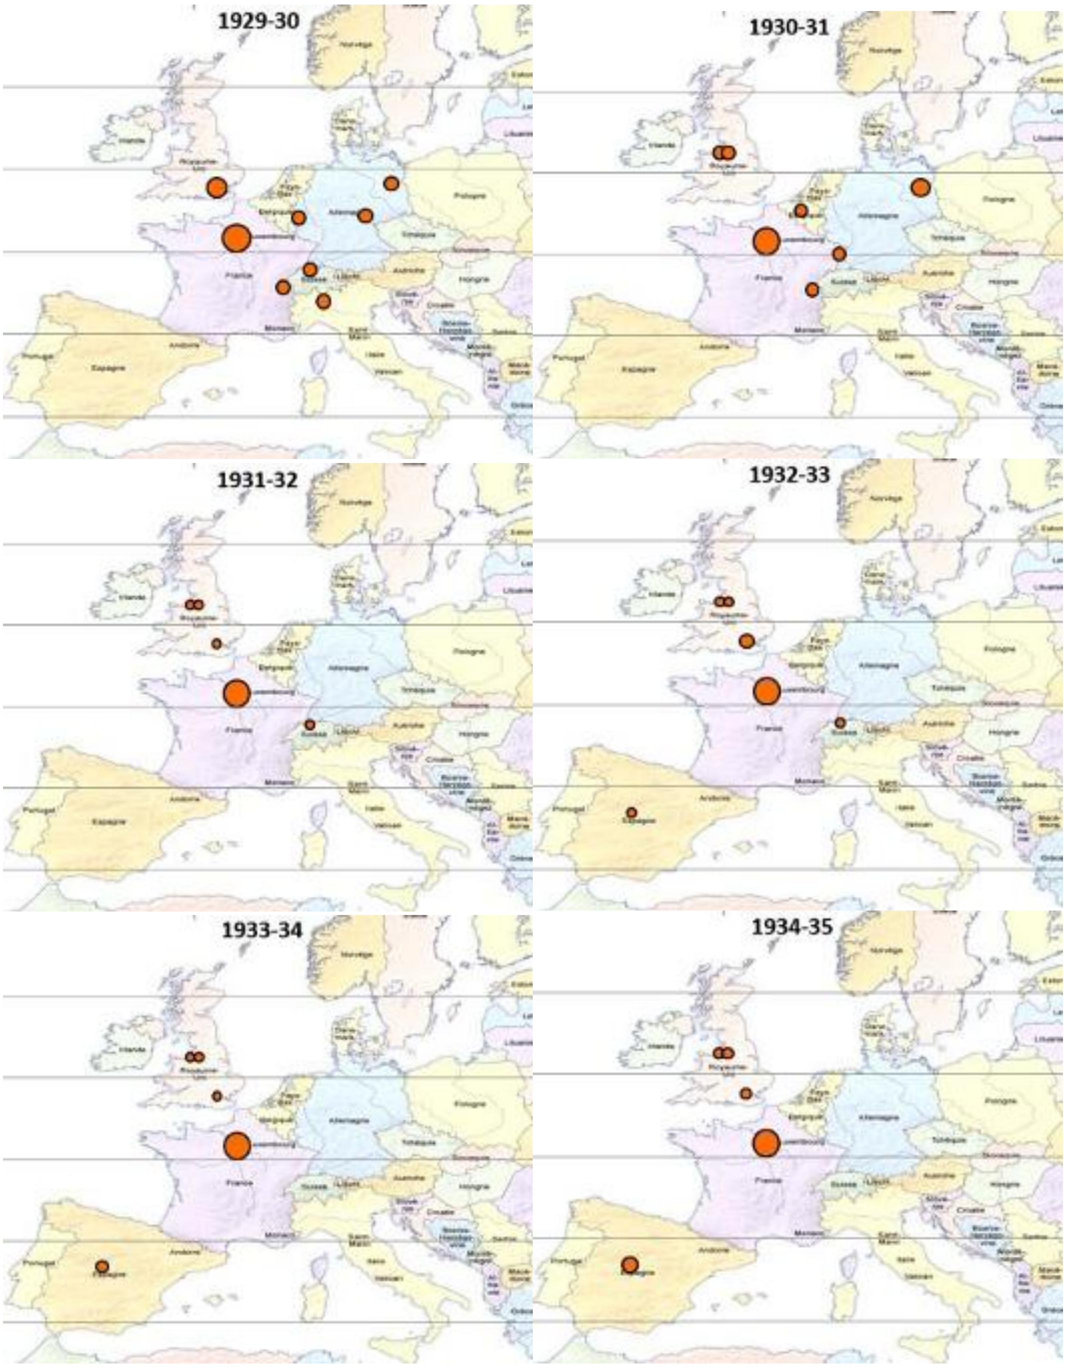

Fig. 2: Sequence showing the destinations for grant holders of Physics, Chemistry, Mathematics and Astronomy.

A dynamic picture of grant holders in Europe as a visible sign of science circulation

We can represent on a geographical map the places where JEN grant holders have been, considering a specific scientific discipline at a given year. Then we can use the stroboscopic representation method to illustrate the flow of time. This is similar to what happens when we are studying the movement of an object through a set of photos taken one after another in the same break of time.[2] If we watch the sequence of maps with the grant holders' places, we can get an idea of

---

[2] We have annual information about the number of JEN grant holders in foreign countries for the period 1929-1938, which is different from having continuous information through time. In Physics, the science that studies movement, when there isn't enough data to study the movement of an object, one usually recurs to a series of pictures taken at regular time periods, framing different positions of an object

the grant holders' movement. We are showing this process for a group of grant holders of Physics, Chemistry, Mathematics and Astronomy, using maps of Europe (see figure 2).

The above maps sequence can be shown in movement using a computer animated image (GIF). This sequence represents both the movements of grant holders towards their multiple destinies of apprenticeships in Europe and the circulation of grant holders in the European space.

Influencing grant holders' movements in Europe –To select an apprenticeship place

The variation of grant holders in space along time depended at least on two big factors: (A) the European and Portuguese historical context and (B) the motives underlying the selection of each apprenticeship place. Regarding this second theme, we have analyzed the primary Bibliography with the aim of **characterizing the factors** that could influence in the selection of apprenticeships places. This is obviously a subjective construction, but it allowed us to typify some reasons directly influencing that selection.

(1.) The most meaningful motivation to select a place was its scientific proficiency at an international level, due to its outstanding professors or to its great scientific establishments. A grant holder working on a particular theme surely identified the most suitable staging place to him, for instance, an institution where he could enlarge his technical skills. Engaging on a specific professor was meaningful to some grant holders. For instance, the grant holder Francisco de Paula Leite Pinto "Asked to attend the Sorbonne Courses on «Astronomie Approfindie» by professors Andoyer and Lambert and the death of professor Andoyer compelled the grant holder to reconsider its apprenticeship plan".[3] Different personalities could advise grant holders regarding to what they thought to be outstanding places to stage. Those could be, for instance, renowned national professors or another Portuguese grant holders being at foreign places.

(2.) Previous personal contacts among Portuguese personalities and foreign scientists or institutions could influence the staging selection. The Portuguese interlocutor could be some professor related to the grant holder or even himself, as some grant holders staged at foreign places before their JEN's grant. For instance, before 1929 the Botany professor Aurélio Quintanilha had an apprenticeship in Berlin, supported by his Faculty. Having a JEN's grant in 1929-30, Quintanilha was intended to continue his studies in Berlin. For example, in the *Pflanzenphysiologisches Instituti* he would continue his work directed by professor Kniep. He had also grants to Berlin from JEN for the following years 1930-31 and 1931-32.

(3.) Sometimes the grant holder selected an apprenticeship place because the scientific activities undertaken there were similar to his employment institution. At that place he could learn some new aspects to improve his performance. The grant holder Arnaldo Rocha was an example:

> "Before asking JEN's grant he was studying the problem of corrosion in Oporto water […]. The complete range of possible studies couldn't be studied in just one institution […]. JEN gave him a 3 months grant […] to the following institutions […] where a lot of water analysis was performed."[4] JEN's Report to 1930-1931.

Another grant holder, António Costa Cabral, engineer at the Laboratory of Forest Technology of the Superior Institute of Agronomy, made a stage at the Madrid Forest Institute to study a specific method to produce wood pulp because it's application in the national [Portuguese] laboratory would be financially advantageous (JEN's Report to 1930-1931). Two naturalists from the Zoology Museum of the University of Lisbon, Amelia Vaz Bacelar and Fernando Frade Viegas da Costa undertook their stages in Natural History museums from Paris, London and Berlin and visited other European ones (JEN's Report of 1930-1931).

Sometimes it was the grant holders' institution that sent them abroad to get a specific training because they needed to apply the acquired knowledge. The stage of Arnaldo de Almeida Dias was an example: he was Chief of the Neurological Laboratory of the Faculty of Medicine of Lisbon and the Scholar Council of this Faculty charged him, within an official mission, to study "pathological anatomy of the nervous system in Germany" (JEN's Report of 1930-1931).

---

in the same frame –this is a stroboscopic representation. In our case, we can watch a quick sequence in the European maps with the staging places represented using a computer; we compare this to a stroboscopic representation. At this paper we just present the sequence of maps elaborated as we cannot give movement to the sequence.

[3] "Havia pedido para frequentar na Sorbonne os Cursos «Astronomie Approfondie» que os profs. Andoyer e Lambert regiam naquele estabelecimento […]. O falecimento do prof. Andoyer obrigou o bolseiro a requerer à Junta modificação do seu plano inicialmente traçado." JEN's Report of 1930-31.

[4] "Antes de pedir a bolsa de estudo da Junta vinha já a ocupar-se do estudo do problema da acção corrosiva das águas do Porto […] O estudo completo dos métodos de investigação aplicáveis, não podia ser levado a cabo num único instituto […]. Foi-lhe concedida uma bolsa de 3 meses […] nas duas instituições seguintes: […] onde se executa um grande numero de analises de águas […]". JEN's Report of 1930-31.

(4.) Foreign institutions or organizations offered specific courses to Portuguese scientists and JEN grant holders took profit of them. Those institutions usually stipulated the place and even the scientific theme of the apprenticeship. For instance, the Society of Nations organized a Medical Course on Malaria destined to scientists from several countries and JEN grant holder Fausto Nunes Landeiro was engaged in it (1929-30). The General Direction of Health collaborated in this grant as he wanted to profit the grant holder's new knowledge to combat malaria in Portugal. The British Council was another institution that offered JEN its collaboration to grant holders in specific courses, as the two vacancies to Cambridge Colonial Course in 1938. The nominated grant holders were the colonial state workers Octávio Ferreira Gonçalves from Angola and Afonso Henriques Ivens Ferraz Freitas from Mozambique. The British Council supported them by, for example, giving them accommodation at a Cambridge college.[5]

JEN's process to select grant holders could have influenced the staging places selection. At first sight we notice that JEN didn't explicitly assume those influences as it didn't establish explicit rules to manage the grants selection of place or theme. Its regulations only required that the grant holder returned to Portugal after his staging abroad. JEN did not announce to have a bourse on any specific theme or country, but just waited for the candidate's suggestion.[6] This has limited the scientific areas covered, as was told by JEN's secretary Simões Raposo in 1932. However, we should consider that JEN possessed a Science Policy that could influence the selection of apprenticeship places.[7]

Conclusions

Our study allowed us to identify the international scientific places whose professors or institutions attracted JEN grant holders for apprenticeships, in the period 1929-1938. We have analyzed these places considering the grants' scientific areas and its occurrences through time. Focusing on a particular discipline, we can see that the staging places changed geographically through time. Some grant holders of the same scientific discipline chose the same staging places, so there exists a correspondence between a scientific discipline and its characteristic set of places.

If we serialize the maps of Europe with the staging places pinpointed we can construct a "stroboscopic representation" during a sequence of time. This kind of "picture in motion" represents the movement of Portuguese grant holders during the 1930s into the European space and the geographical variation of their staging places through time. This shows that JEN grant holders participated on the scientific knowledge circulation in the international sphere. We are working to discern concrete fluxes of grant holders through space during the referred time period. We also aim at distinguishing the institutions or places that fixed grant holders for most of the time. This is a very complex and lasting analysis that we has just been started.

Having identified a group of scientific places that attracted foreign scientists with learning objectives, we are contributing to understand the circulation of scientific knowledge around 20th-century Europe. However, this conclusion is limited by the fact that we are just considering the Portuguese grant holders. If we congregated the data of grant holders from several European countries, we would get a more comprehensive representation than ours. Then we could watch the geographical changing of apprenticeship places using a motion picture, and this would be a dynamical representation of the international circulation of scientific knowledge.

THE PRINCIPLE OF POPULARIZATION OF ENERGY

Abstract

We will examine the emergence of the principle of conservation of energy and its relation to the rise of science popularization.

On the one hand, the principle of conservation of energy is an uncommon example of widespread and simultaneous discovery. In fact, more than ten authors can be mentioned as discoverers or inventors of this fundamental principle, all during the middle of the 19th century. Although its genesis was closely related to research on the nature of heat, energy conservation did not arise to solve any specific age-old problem, nor did it belong to any specific theory. However, once firmly established, it has grown to become one of the most unquestioned principles of science.

On the other hand, popular science publishing underwent a notable, if not a radical transformation in the second half of the 19th century. Not only did this consist of a quantitative increase in scientific content; there was a significant qualitative change as well. In the 20th century, especially after World War II, popularization experienced again a radical change. Today, mention in the media of new scientific advances is far from scarce. In all of this proliferation the concept of 'energy' plays a crucial role. Moreover, its use has grown beyond scientific spheres, and we can now find it even in the most varied contexts. 'Energy' has become a ubiquitous word.

Is 'energy' an especially well-suited concept for popularizing purposes? It has been stated that the concept of energy had already existed in the minds of some of the authors involved prior to its 'discovery' as a metaphysical concept. Therefore, is this a case where society at large has come to influence technical and specialized research? Influences in both directions will be considered.

That the word *energy* is probably the most ubiquitous among those who live halfway between technical and common use is apparent at every turn. Perhaps the term *force* is one of its most serious competitors. However, with 'force', we usually can distinguish between its technical and common uses. On the contrary, the malleability of the meaning of energy is such that in many cases it is supposedly used with the same meaning. In a certain sense, energy is "malleability" itself, the pure "transformability," or "convertibility". One would never find "pure" energy, except in sport journalists' clichés. As Max Planck suggested in his book *On the Principle of Conservation of Energy* in 1887, little more can be said –or must be said– about energy besides that its amount is conserved.[1] Hendrik Kramers, who took active part in the construction of quantum mechanics, admitted that «the most fruitful concepts are those to which it is impossible to attach a well-defined meaning.» Energy is one of them.[2]

Digital age allows us to prove in few seconds that there's not a day in which the term «energy» does not appear in the newspapers. Ecology and energy industry have placed the word in the foreground of the news. There, it appears very often in relation to energy waste, global warming, or actions that a certain Minister of Energy or Energy Committee have decided to carry out.

Also the success of self-help manuals and recipes on how to live a full life has contributed to the omnipresence of the word.

Last but not least, the continued growth of scientific popularization industry allows the word to be over and over again a liaison between the jargon of the specialists and that of the common.

A History of Energy Popularization

As suggested by the title of our communication, the question we asked ourselves at the very beginning of our research was when and how this successful process of popularization took place. In other words, we wanted to do a history of the popularization of energy.

After our first steps in this direction, we realized that this approach needed to be nuanced in depth, if not radically changed. Firstly, because as Johnathan Topham and Bernadette Bensaude-Vincent, among others, have argued, the pattern *first-discovery –then-popularization*, can be naive or, in many cases simply false.[3] When scientists popularize for scientists –which happens quite often– they are forced to find new metaphors and reformulations which can really help themselves to rediscover what they were eager to popularize. Summarizing, we shouldn't understand popularization as a passive stage in the scientific development. This perfectly suits to the emergence of the conservation principle. Its consolidation as one of the firmest principles of physics took place for 20 or 30 years in which communications among scientists and communications to a wider audience –almost always educated people– played a crucial and active roll.

Even more. It's not appropriate to talk of «popularization» in the period in which the principle of conservation took shape. Certainly, at that time the expression "popular science" had been coined, but not «popularization.» Quoting once more Bensaude-Vincent, in those days «popular science» did not necessarily entail «science popularization». The gap between the professional and the amateur was not yet as wide as it became at the turn of the century, and much less than it is today, when at Geneva records on energetic collisions are broken in experiments in which more than 40 countries are involved and the same paper is signed by thousands of professional scientists.

This gap came a little earlier in the field of physics than in other disciplines. In the prologue of the first edition of the above-mentioned book by Planck, he expressed his displeasure with the fact that up to then, in 1887, the conservation principle had only been treated by specialists with a too much narrow focus, and in general books with a non-technical approach, with the exception of Hermann Helmholtz's memory.[4] Dan Wegener has seen in this work by Planck an attempt to demarcate the incipient field of theoretical physics.[5] We believe that Planck's intention can be further taken: He was attempting to distance physics from popular science through giving energy the rigor it lacked.

Following Buchwald and Hong, it can be said that «physics circa 1900 was the general science of matter and energy, exclusive of the properties by specific substances which may combine to form new substances».[6] Planck himself said, in 1905, that "besides the concepts of space and time, the concept of energy is the only one that is communal to all domains of physics."[7] Therefore, the emergence of energy doctrine is closely related to the birth of the discipline we nowadays call *Physics*.

The Principle of Conservation of Energy

Turning now to the History of the Principle of Conservation of Energy, we can say –again with Buchwald and Hong– that we lack a "comprehensive treatment" which includes the various studies devoted to different countries, disciplines, traditions and scientists. We can revive Planck's complaints, now referring them to the history of energy. Anyway, our communication is greatly indebted to the previous works by Kuhn, Elkana, Myers, Rabinbach, Smith, Harman, Brush, and Clarke, among others.[8] Also the papers by Pohl-Valero on the Spanish case are being quite helpful.[9]

Note the amount of different issues related to the question we raised. This wide scope affects not only traditional historiographical divisions such as internalism vs. externalism, but also to a tremendous complexity in the mutual influences of different factors in a crucial period of the History of Science. Thus, we are forced to escape specialization. What we present in this brief paper are not our definitive conclusions, but the current state of our research. Needless to say, any suggestion or objection from the improbable readers will be more than welcome.

As for the conservation, it is widely known that many authors made independent statements with very similar undertones in a relatively short time span, say between 1840 and 1850. Roughly speaking, the sources can be reduced to two: Germany, where the main character is Herman Helmholtz, and Great Britain, where it is more difficult to point a leader. In Germany, the interest in the preservation of what Helmholtz initally named "Kraft" came mainly from the fields of physiology and medicine. Many researchers were then interested in animal heat and vital dynamics. To this tradition belong the chemist Justus von Liebig, Dr. Robert Mayer –for many the true discoverer–, and also the polymath Helmholtz. The latter presented in 1847 the most technical and complete version of the principle, which included many of the previous results on the subject.[10] Helmholtz was fully aware that rather than an empirical discovery, his work was a kind of a general research program. He presented his report in the *Physikalische Gesellschaft* in Berlin, founded only two years earlier. The attempt to distance from the *Naturphilosophie* and its metaphysical speculations in the field of natural sciences had led to six enthusiast scientists (only three of them physicists) to found a new institution.[11] The old guard of Berlin did not support the proposal by Helmholtz. Johann Poggendorff refused to publish Helmholtz's memoir in the *Annalen*.

But the idea settled down in the next few years, especially after Clausius joined the Society in 1852. Three years later, for example, the academicians launched a competition to get an accurate measure of the mechanical equivalent of heat.

In Britain, also a young institution saw the emergence of the principle of conservation: the *British Association for the Advancement of Science*. It was founded in 1831 with the certain intention of regenerating British science and "to incorporate a love of knowledge with the very frame of the country."[12] There, James Joule presented his first measures of the mechanical equivalent of heat in 1843, in Cork. There, William Thomson knew about Joule's results in 1847, in Oxford. And there, the use of the word "energy" was definitively coined. Unlike the Germans, the British were deeply involved with the industrial world. For instance, William Rankine, one of the main architects of thermodynamics, was for many years Regius Professor of civil engineering and mechanics at the University of Glasgow, and had also worked for shipbuilding companies.

Very soon, interactions among the two traditions took place. Some of these interactions were in the form of priority disputes and restatements. It is interesting to note the fast conjugation of traditions that were based on seemingly such disparate interests: in the islands, increasing profitability of machines; in Germany, the desire to finish with the mystique of the vital forces.

Thermodynamics and the Second Principle

The consolidation of the conservation principle is closely related to the emergence of thermodynamics. In mechanics, since Helmholtz memory, the principle had been demonstrated (for conservative systems, of course). After that, what was needed was the quantitative relation of ancient *vis viva* to other forces of nature. There is little doubt that the mechanical equivalent of heat was one of the mostly quoted evidences in this sense. To be sure, the growing concern in heat-machines

[12] Quoted in CANNON (1978), 169. It is an excerpt of the speech given by the first president of the Association, Earl Fitzwilliam, at the third meeting, held in Cambridge in 1833.

research was probably the main reason for this interest, which can already be found in the foundational memory by Sadi Carnot in 1824.[13]

Thermodynamics –another term coined by the British– cannot be considered as completely formulated before the enunciation of its second principle. Although anticipated to some extent by Carnot, it was only clearly stated in the works by Thomson and Rankine in the fifties, and through the introduction of the concept of entropy by Clausius in 1864. Clausius justified the choice of this term for its resonance with "energy." Unlike the latter, 'entropy' was a neologism.

The successful spread of the principle of conservation and of the term energy itself was often accompanied by the idea of irreversibility and degradation which the second principle introduced. That law, smaller in scope than the first but much more attractive for transpositions or cosmological applications, contributed a great deal to shape the principle of conservation.

The allegory of the "Heat Death" of the universe was recognized in the fifties by Clausius, Helmholtz and Thomson. For instance, in the famous reversibility objection raised by Joseph Loschmidt against the probabilistic interpretation of the second law by Ludwig Boltzmann –objection, by the way, previously formulated by Thomson–, the Viennese physicist clearly showed the «terrifying» character that the second principle had already taken in 1876:[14]

> [My intention is to]…destroy the terroristic nimbus of the second law, which has made it appear to be an annihilating principle for all living beings of the universe; and at the same time open up the comforting prospect that mankind is not dependent on mineral coal or the sun for transforming heat into work, but rather may have available forever an inexhaustible supply of transformable heat.

In the context of spiritual affairs, the idea of degradation of energy was clearly expressed by reverend Thomas Hill, ex-president of Harvard College. In his article «On the Correlation of Forces» he wrote that:

> A ditcher or hod-carrier may use as much muscular power in the twenty-four hours as the most graceful and accomplished acrobat; and some dull student, stumbling for weeks in the vain attempt to cross the 'pons asinorum,' will use as much brain power, measured in the amount of phosphorous assimilated from his food and eliminated again from his body as William Rowan Hamilton used in creating the new science of kinematics, or the new calculus of Quaternions.

In this excerpt revered Hill points the place for the second law of thermodynamics: even though energy is conserved, one has to make good use of it.

We have found a review of this paper –whose exact reference we don't know– literally stuck inside the cover of a copy of the anthology on *The Correlation and Conservation of Forces*, by Edward Youmans.[15] We assume that who ever posted this review had the intention to add a forceful support to Youmans' purpose, openly anti-materialist. The anthology, edited in New York in 1868, contains expositions by different authors, and was intended for the spreading of the new ideas in the States.

His specific audience was American science teachers and, indirectly, textbooks editors. In this anthology we can find references not to entropy itself, but to dissipation and irreversibility. For instance, in the conference by Helmholtz, held in 1854 in Könisberg before a non-scientific audience, we already find the fiction of eternal death. William Grove did not dwell on this aspect, but did mention dissipation and irreversibility as a very probable fact (this volume contains the fourth edition of Grove's book, from 1862).

Popularization of Thermodynamics

The concept of energy joined the journalistic and artistic vocabulary during the seventies. According to the physicist Balfour Stewart, when intellectuals started writing books in which the two laws of thermodynamics were mentioned, energy was already a perfectly intelligible word in British society. He stated:

> By energy, we mean the power which a man possesses of overcoming obstacles; and the amount of his energy is measured by the amount of obstacles which he can overcome, by the amount of work which he can do.[16]

---

[13] CARNOT (1824).

[14] Quoted in BRUSH (1978), 66. It belongs to LOSCHMIDT (1876), 135.

[15] YOUMANS (1868).

[16] Quoted in MYERS (1989), 323. It belongs to a paper by Balfour Stewart and J. Norman Lockyer of 1868 entitled "The Place of Life in a Universe of Energy," *Macmillan's* 20, 319.

Cosmovisions inspired by thermodynamics conceived nature as a machine capable of producing mechanical work or –as Helmholtz would call it– workforce. The industrial machine was adopted as a model of the universe and nature became the source of endless power for society.

Popular scientific literature took profit of this image. According to Myers, Stewart and Tait thought that laws of physics and those of capitalism were entangled as soon as 1875.[17] Quoting Wegener:

> Psychiatrists such as Beard spoke in 1881 of mental exhaustion as the "bankruptucy" of nervous energy. Similarly, Krafft-Ebing used, in 1885, terms like "Nervenkapital," "Nervenarbeit" and "Arbeitskapital" interchangeably... But, by far, the most common analogy was comparing exchange of money in the society with an exchange of energy in the physical world.[18]

In fact, in the above-mentioned conference by Helmholtz in 1854, he already had used this analogy.

The term 'energy' was immediately endowed with metaphysical considerations. We think that the generalization of the concept of entropy precipitated its insertion in the social imaginary of the period. Balfour Stewart published one of the first popular books entitled *The Conservation of Energy*, in 1873, in which he already discussed the second principle. Two years later, along with Peter Guthrie Tait, he published *The Unseen Universe*, where the authors distinguished between the imperishable, invisible and eternal world, and the visible, perishable, and mortal.[19] In Germany, materialists also echoed the second principle. Nietzsche himself quoted William Thomson and the heat death in his writings of the eighties.[20] He had known about this result through the book *Die Kraft*, from the German physiologist Johannes Vogt.[21] In a newspaper article published in one May the first, the Spanish Nobel laureate José Echegaray advocated for a peculiar application of Carnot's principle: only social inequalities allow work performance.[22] It was not the only time someone in Spain put heat death at the same level of egalitarianism. A similar argument was defended at the *Ateneo de Madrid* by Laureano Calderón in 1891.[23] He was claiming to avoid the state interference in the affairs of citizens.

Science Fiction, at least as futuristic speculation, reached its peak, if not its birth, in this same period. In 1871, Edward Bulwer-Lytton published an odd novel entitled *The Coming Race*, which set the action in an underground world, inverting the Victorian Platonism. Allegoric visions of thermal death were also reflected by Flammarion's scientific positivism in *La fin du monde* in 1893: the figure of Death reigning over a planet without life or the spectral representation of a human race perishing of frozen cold are some of the allegories that came from Thomson and Clausius ideas.

However, paradoxically, popularization of energy did not entail popularization of physics; on the contrary, physics became less accessible at the end of the century, and its authority increased by lots. The claim by Planck with which we began our communication was a response to the great variety of meanings which were attributed to energy in popular science, and different scientific disciplines. Planck's attempt to separate Physics from amateur speculations is the best evidence of the presence of the conservation principle in the popular and artistic imagery of the third quarter of the nineteenth century.

Concluding Remarks

Many of the current responses to the periodic energy crisis are the distant echoes of the foundational nature of energy: the second law and the idea of degradation and profitability have accompanied energy almost since its first appearances. The catastrophic implications of energetic collapses are not new. 'Energy' is nowadays as ubiquitous as still indefinable. Although we cannot properly say what energy is, we do know how much it costs, and we think that we know what would happen if we don't manage it properly.

THE NEW NON-CLASSICAL

Peeter MÜÜRSEPP
Tallinn University of Technology, ESTONIA
peeter.muursepp@tseba.ttu.ee

Abstract

The paper addresses a possible shift in the classification of science into classical and non-classical. It has been widely accepted that Galilean-Newtonian mechanics is the basis and best example of classical science, while quantum mechanics and the theories of relativity play the same role at the non-classical side. Some methodologists (most notably Prigoginians) claim that in addition to the mentioned distinction one should speak about post-non-classical science. The latter case of Ilya Prigogine's conception (theory?) of self-organization has been taken as the model case. The third member in the classifying sequence, however, has failed to gain general recognition. It is obviously possible to drop the post-non-classical story as an overestimation of the influence of some relatively marginal approach to the scientific method. However, another solution is possible as well. As a matter of fact, one can view both the theories of relativity and quantum theory as classical and move the dividing line between two types of science closer to the present day in the history of science. Quantum mechanics is quite different from the classical one in several significant ways, i.e. indeterminism and the role of the observer, to name just some of the most influential ones. It may look as if self-organizationists did not really do anything else but put a stronger stress on some aspects already put forward by the big wigs of the non-classical approach. However, it is the issue of irreversibility that may well turn the tables here. The Schrödinger equation is reversible. For Einstein, time was just an illusion. It is Prigogine, who has been consistently claiming that irreversibility is an objective fact inherent in nature and not something that subjectively seems to us humans due to the limited character of our knowledge. It appears that we cannot get rid of irreversibility in principle just like the Eleatics were not able to arrest the Heraclitean change.

Introduction. Why Was Classical Science Classical?

It is normally held that Modern European Science started with Galileo. The reasons for this claim to hold are sometimes considered self-evident. Galileo was an experimenting scientist. Of course, the role of the experiment is very important for that matter. However, just experimentation could hardly bring anything new into the intellectual activities of the time. Alchemists had been furiously experimenting for quite a while. Still, the methodologists and philosophers of science of today do not tend to call them the initiators of the Modern scientific method. The experiment is part and parcel of the scientific activity of modernity. But not any kind of experiment can do the job. The experiment has to be systematic. It has to be based on a hypothesis which is scientific, i.e. which can be verified or falsified. The alchemists normally did not care for the latter task. This gives us evidence that the priority of Galileo is due to the ability to present hypothesis that were testable, that could be verified or falsified by experiment. This does not mean that he succeeded in his task of verification. But the pace was set.

We still didn't answer the main question here. Namely, what is classical about Galileo's approach to the experiment? Systematic approach to the issue based on the scientific hypothesis is an important part of the matter. The core question, however, is reversibility. Galileo stands for the requirement that each and every scientific result has to be achieved repeatedly. Reversibility becomes the core of the classical scientific method. Time is thrown overboard. It has been declared nothing more than an illusion, an example of human ignorance.

The position of the Eleatics prevailed over the Heraclitean world view for centuries. Common sense and sense perception lost the battle to pure reason just like Achilles was never able to catch up with the slowly moving tortoise in the famous paradox of Zeno, the follower of Parmenides for whom nothing existed except the one and only unchangeable whole. Still, this was the beginning of theoretical thinking. By all means a great achievement of the human intellect that enabled us to progress towards a high-tech civilization. Still, the approach has to be changed in order to avoid a dead end as we'll see below.

Why is Quantum Mechanics Still Classical?

Classical mechanics, started by Galileo and elaborated by Newton, was classical by definition. It still serves as the model case for the ideal of being scientific. Quantum theory seems to be quite different and really is such. It is normally taken to be the model case of non-classical science.

We need to answer two symmetrical questions here. Namely, what is new and what is old in quantum theory? We are back to the experiment. Now we need to pay special attention to the observer. In the very classical case the observer is there but she is not part of the experimental situation. She is rather in a God-like position arranging the situation from above and observing it repeatedly. As a matter of fact, repetition of an experiment in the strict sense of the word is an Achilles-tortoise type illusion. But this does not prevent classical scientists to apply the concept and make it a centre-piece of the method from the application point of view.

In quantum mechanics, as we know, the observer necessarily intervenes into the system disturbing it, actually breaking it, making measurement impossible. In a way, this makes the process under study irreversible. Strangely enough, the disastrous intervention of the observer into the quantum world still means a step further in the development of science itself and even its methodology.

Another novel moment is bringing in probabilities into decision making concerning experimental results. This move enables fluctuations to come in. But the need to reverse, to repeat is still there. Statistics won't turn it around. After all, the Schrödinger equation is reversible. The breakthrough was never achieved.

Ludwig Boltzmann and the Arrow of Time

The conception of the arrow of time comes into the methodology of science through the developments concerning entropy associated with the second law of thermodynamics. The role of Rudolf Clausius cannot be overestimated in this respect.

After Clausius came Ludwig Boltzmann, the Charles Darwin of physics. It was Boltzmann who identified the time paradox in the second half of the nineteenth century. For Boltzmann, the whole nineteenth century was the century of Charles Darwin. Thus, he tried to formulate an evolutionary approach to physics as well. In doing so, he came face to face with the problem of the objectivity of knowledge. The laws of Newtonian physics had represented the ideal of objective knowledge for a long time. Any attempt to confer a fundamental meaning on the arrow of time was resisted as a serious threat to this ideal. In Boltzmann's time, Newton's laws were still considered final in their domain of application.

Boltzmann was well aware that nothing analogous to irreversibility exists in classical dynamics. He thought that he had successfully proved the determination of the arrow of time by the evolution of the dynamical systems from less probable conditions to more probable ones. He concluded that irreversibility can be derived only from assumptions about the initial conditions in the early stages of our universe. Boltzmann was convinced that in order to understand nature we have to include evolutionary features and that irreversibility, as defined by the second law of thermodynamics, was a decisive step in this direction. But he was also heir to the grand tradition of dynamics and realized that it stood in the way of his attempt to give a microscopic meaning to the arrow of time. Boltzmann's probability-based interpretation makes the macroscopic character of our observations responsible for the irreversibility we observe. If we could follow the individual motion of the molecules, we would see a time-reversible system in which each individual molecule follows the laws of Newtonian physics. According to this interpretation, irreversibility is not a basic law of nature but merely a consequence of the approximate, macroscopic character of our observations.

The objections of Ernst Zermelo and Henri Poincaré made Boltzmann change his position. As the result, Boltzmann gave up the idea of the objectivity of the arrow of time, reducing it to the level of our subjective conceptions, which we as human beings impose on reality. As a result, the notion of the arrow of time was relegated to the realm of phenomenology.

"We, as imperfect human observers, are responsible for the difference between past and future through the approximations we introduce in our description of nature" (Prigogine 1997: 2). Thus, irreversibility would correspond only to an appearance that is devoid of any fundamental significance.

According to Ilya Prigogine, the failure of Boltzmann was caused not only by his inadequate response to criticism but also by his incorrect interpretation of the second law of thermodynamics. Boltzmann considered the second law a practical principle expressing only practical improbability of one process or another. Prigogine himself, however, postulates the second law of thermodynamics as a fundamental theoretical fact, as a principle of selection leading to the breaking of time symmetry (Näpinen and Müürsepp 2002: 467).

It is Boltzmann's big tragedy that he is often credited with having shown that irreversibility is only an illusion. True, he really made the logical error relying on trajectories. Trajectories are time-reversible, however numerous.

Ilya Prigogine on the Arrow of Time and Irreversibility

Ilya Prigogine has called the denial of the *arrow of time* the main problem addressed in his book *The End of Certainty* (Prigogine 1997). According to Prigogine, it is the so-called *physics of nonequilibrium processes* that describes the effects of unidirectional time and gives fresh meaning to the term 'irreversibility'. Prigogine holds that irreversibility leads to a host of novel phenomena, such as vortex formation, chemical oscillations, and laser light, all illustrating the essential constructive role of the arrow of time. From this, it is clear already that irreversibility serves as the physical basis of the arrow of time for Prigogine. He illustrates his position with a metaphor: matter at equilibrium, with no arrow of time, is "blind", but with the arrow of time, it begins to "see". Prigogine adds that we are actually the children of the arrow of time, of evolution, not its progenitors (Prigogine 1997: 3).

The other crucial development in revising the concept of time was the formulation of the physics of unstable systems. Classical science emphasized order and stability. Now we see fluctuations, instability, multiple choices and limited predictability at all levels of observations. When appropriate initial conditions are given, we can predict with certainty the future or "retrodict" the past. Once instability is included, this is no longer the case and the meaning of the laws of nature changes radically, for they now express possibilities or probabilities, not certainties.

It is interesting to note that Prigogine traces the modern history of the arrow of time back to the eighteenth century, when Jakob Bernoulli presented his pioneering work in games of chance. Sensitivity to initial condition is really observable in Bernoulli's work. Two numbers differing only very slightly initially will differ by 0.5 after 40 steps. Thus, the so-called Bernoulli map introduces an arrow of time that can only point in one direction. Here, the time symmetry is broken at the level of the equation of motion, which is thus not invertible. This is in contrast to the dynamical systems described by Newton, whose equations of motion are invariant with respect to time inversion. There is no indication, however, that Jakob Bernoulli himself paid any attention to irreversibility as a concept in the context of his studies. In this sense, it is still Boltzmann, who has the priority. In any case, the arrow of time already exists at the level of equations of motion. However, the baker map provides a more general description of the emergence of irreversibility in invertible dynamical systems.

In a celebrated statement, Max Born asserted that "irreversibility is the effect of the introduction of ignorance into the basic laws of physics" (Born 1960). Prigogine's firm position is, however, that the laws of physics, as formulated in the traditional way, describe an idealized, stable world that is quite different from the unstable, evolving world in which we live. The main reason to discard the banalization of irreversibility is that we can no longer associate the arrow of time only with an increase in disorder. Recent developments in non-equilibrium physics and chemistry unambiguously show that the arrow of time is a source of order.

The constructive role of irreversibility is clearly seen in far-from-equilibrium situations where non-equilibrium leads to new forms of coherence. Prigogine believes that it is precisely through irreversible processes associated with the arrow of time that nature achieves her most delicate and complex structures (Prigogine 1997: 26). Therefore, we can see that Prigogine associates irreversibility with the arrow of time. There is no indication, however, that we can obtain the arrow of time only in the irreversible world of non-equilibrium physics. Moreover, Prigogine's formulations raise the question, whether he imagines that there can be irreversibility not associated with the arrow of time and if so, in what sense?

This problem concerns an important aspect of the time paradox, "interface between mind and matter". If the arrow of time existed only because our human consciousness interfered with a world otherwise ruled by time-symmetrical laws, the very acquisition of knowledge would become paradoxical, since any measurement already implies an irreversible process. If we wish to learn anything at all about a time-reversible object, we cannot avoid the irreversible process involved in measurement, whether at the level of an apparatus or of our own sensory mechanisms. Thus, in classical physics, when we ask how we can understand "observation" in terms of fundamental time-reversible laws, we get "nonsense". In classical physics we can neglect this "nonsense" due to the great success of classical dynamics. In quantum theory, however, the situation is quite different. Here we need to include measurement in our fundamental description of nature. It seems that we have an irreducible duality: the time-reversible Schrödinger equation and the collapse of the wave function. By going beyond a reductionist description we can give a realistic interpretation of quantum theory. This is possible by incorporating Poincaré resonances into a statistical description and deriving diffusive terms that lie outside the range of quantum mechanics in terms of wave functions. The measurement device has to present the broken time symmetry. In this sense, there is a privileged direction of time, as there is a privileged direction of time in our perception of nature. This *arrow of time* is the necessary condition of our communication with the physical world. It is the basis of our communication with our fellow human beings.

Stephen Hawking takes an analogous position, answering the question, why do we observe that the thermodynamic and cosmological arrows point in the same direction. "Conditions in the contracting phase would not be suitable for the existence of intelligent beings who could ask the question: Why is disorder increasing in the same direction of time as that in which the universe is expanding?" (Hawking 1989: 159-160). Still, in the end, for Hawking time remained just an accident of space, supported by the *anthropic principle*. However, there is an important position that Hawking holds. He emphasizes that in addition to the thermodynamic and cosmological arrows of time there is the psychological arrow. Stephen Hawking argues that the psychological arrow of time is determined by the thermodynamic arrow (Hawking 1989: 153). His position is that psychological arrow is actually essentially the same as the thermodynamic arrow. They always point in the same direction (Hawking 1989: 160). This idea is an important step forward in the understanding of how human beings can make a better sense of the universe. "The progress of the human race in understanding the universe has established a small corner of order in an increasingly disordered universe (Hawking 1989: 161).

Ilya Prigogine takes an even broader look. According to him, the arrow of time plays an essential role in the formation of structures in both the physical sciences and biology. However, there is still a gap between the most complex structures we can produce in non-equilibrium situations in chemistry and the complexity we find in biology.

Irreversible processes describe fundamental features of nature leading to non-equilibrium dissipative structures. Such processes would not be possible in a world ruled by the time-reversible laws of classical and quantum mechanics. Dissipative structures require an arrow of time. The existence of the arrow of time is not a matter of convenience. It is a fact imposed by observation.

As already mentioned above, Prigogine postulated the second law of thermodynamics as a fundamental *theoretical* fact, as a principle of selection leading to the breaking of time symmetry. Just for this reason he creates the new physical and mathematical concepts. He treats the breaking of time symmetry as an *inner* quality. "Only the treatment of time as an *operator* by Prigogine can make it possible to explain the inner breaking of time symmetry simultaneously in mechanics, quantum physics and relativity theories" (Näpinen and Müürsepp 2002: 467). The word "inner" means that the breaking of time symmetry is not forced by new interactions with the outside world. The *time operator* is closely connected to the *microscopic entropy operator*. Through non-canonical (non-unitary –in quantum mechanics) transformations, the *evolution operator* with the inner time symmetry breaking is reached. This chain of novelties leads to the physical-mathematical description with unidirectional –from past through present into future– time. Many scientists still believe that some events are evolving in one direction only because the evolution in the opposite direction would have a very small probability but is still possible. The conviction of Prigogine is different. Only because some states are strictly forbidden and they cannot be discovered in nature and artificially prepared, the probabilistic character can be ascribed only to the states that are allowed. According to Prigogine's idea, the inner breaking of time symmetry leads to physical evolution that is describable by a representative non-unitary *semigroup*. The latter expresses the second law of thermodynamics.

It is important to emphasize that Prigogine does not connect this law with the experimental situation and thermal machines. The scope of this law is much broader. In Prigogine's interpretation, this law claims, in its most essential sense, that there is a quantity in nature which, during all the changes occurring in nature, changes only in one and the same direction. If there are quantities in the world, which change only in one direction, there are also states, which change only in one direction.

It is important to understand that trajectories and even wave functions are not enough to account for irreversibility. We need to apply the so-called *Poincaré resonances* (coupling of degrees of freedom that lead to divergent expression due to small denominators if there is resonance between them). Accepting the considering of *irreversibility* as the basic element of description of the physical world, referring to the position of the mathematical description of large physical systems that lies in the infinity of a number of degrees of freedom (Näpinen and Müürsepp 2002: 477).

Obviously, Prigogine is interested only in the description of reality in the most comprehensible way, invoking the best of the scientific method. Thus, he treats irreversibility and the arrow of time in close contact or even as synonyms. Prigogine may not have been aware of the logical possibility of separating the arrow of time from irreversibility. It is more probable, however, that this possibility did not have any significance for him. The arrow of time is just a metaphoric expression for irreversibility, which he understands in a broad physical sense.

Conclusion

The analysis provided above yields evidence that the positioning of the demarcation line between classical and non-classical science can be and probably has to be disputed. Obviously, quantum theory cannot be taken as just an extension to the classical Galilean-Newtonian approach. However, the breakthrough into principally new understanding of nature, new dialogue with it for humans has not been achieved by the quantum theorists. They lacked the necessary dose of innovative thinking. The genius of Stephen Hawking, however, has been focused on mathematical models of the universe and only occasionally made excursions to the philosophical plane with no intention of making his presence really felt in this field. Still, the breakthrough was achieved in the second half of the twentieth century by Ilya Prigogine and his followers.

There is another idea present to set the terminology of the methodological changes by calling the latter post-non-classical approach to science. However, such solution would distort the picture by displaying the great breakthrough of Prigogine in a negligibly insignificant way. The approach deserved to be called the new non-classical one.

CIRCULATION OF IDEAS AND FORMATION OF SLOVAK PHYSICS

Juraj ŠEBESTA
Department of Theoretical Physics and Physics Education,
Comenius University in Bratislava, SLOVAKIA
sebesta@fmph.uniba.sk

Abstract

The formation of Slovak physics is a pregnant example of the importance of idea circulation. Before 1918, no university existed in the territory of modern Slovakia. After the birth of Czechoslovakia, Comenius University was established in Bratislava, but without a faculty of science. So whoever was interested in the study of science was forced to move to Prague, Brno or foreign cities. Three young men were studying at Charles University in Prague in 1925-29 – Dionýz Ilkovič and Ján Fischer from Slovakia, and Vilém Kunzl from Czech city of Plzeň. The first one was appointed (1940) professor of technical physics in Bratislava's Technical University, and after a faculty of science was established in Bratislava he was also appointed professor of physics there. He founded the undergraduate study for future physics teachers and future physicists, and started physical research. First, his followers moved to Košice at the beginning of the 1950s to found a second Slovak centre of physics.
Owing to Ilkovič's effort, V. Kunzl was appointed professor of physics at Comenius University in 1947. In 1948-52 Kunzl founded four physics branches which are cultivated there up to now. So he is considered the founder of experimental physics at CU. Besides that, owing to his effort Ján Fischer came to CU. In 1928-31 Fischer finished his PhD study at ETH Zürich under supervisor prof. G. Wentzel. J. Fischer completed two papers here which became foundation stones of quantum theory of interaction between radiation and matter. He is deservedly considered to be the founder of Slovak theoretical physics.
No doubt, D. Ilkovič, J. Fischer, and V. Kunzl became founders of Slovak physics owing to their high-quality training at Charles University in Prague. Moreover, creating a new branch of science and forming undergraduate training they used fairly all experience, methods, and ideas which they met in Prague. In the 1950s Czech theoreticians promoted to build up a Slovak school in theory of elementary particles.

The formation of Slovak physics is a pregnant example of the importance of idea circulation. Before 1918 neither acollege nor a university existed in the territory of modern Slovakia. Hungarian Elizabeth's university, established in the year 1914, did not start lectures before the end of World War I. In 1919 Comenius University was established in Bratislava, originally as a traditional university with four faculties, but for three decades there were only three faculties: during the first school year 1919/20, the Faculty of Medicine functioned. The second and the third ones –the Faculty of Philosophy and the Faculty of Law– started to prepare university-educated specialists two years later. However, the Faculty of Natural Sciences was not established at all during the pre-war Czechoslovac republic.

So anybody who was interested in studying science, including mathematics and physics, was forced to move out to Prague, Brno or any foreign cities. However, in November 1939 all Czech universities were closed because of students' disorders connected with German occupation. After that, all Slovak students had to go back to Slovakia as Bohemia had turned into a part of Germany as the Bohemia and Moravia Protectorate, and Slovakia became an autonomous country under the auspices of the Third Reich. In the school year of 1939/40, as there was no Faculty of Sciences at Comenius University, future mathematicians and physicists or future teachers of these subjects had to enter the Faculty of Philosophy. As usual, they enrolled to some subjects closer to their interests. Fortunately, at that time there was lecturing on physics at the Institute of technical physics of the Slovak Technical University in Bratislava.

However, in the winter semester of 1939/40 there was a theoretical opportunity only because prof. Josef Sahánek, the first head of the Institute of Technical Physics of the Slovak Technical University, had left Bratislava as he was appointed professor of technical physics at the Technical University in Brno. Things became more favorable when the new head of the Institute of Technical Physics was appointed. It was Dionýz Ilkovič. He took the lead of the Institute at the beginning of February 1940. It is the starting point for the forming of Slovak physics. Why? And how had circulation of ideas taken place in this case? To answer these two questions we have to say a few words about his study.

Dionýz Ilkovič had studied at the Faculty of Sciences of Charles University in Prague in 1926-30. From the point of view of our subject, several factors had been very important:

Young Dionýz completed his education in Prague on chemistry, teaching of chemistry, physics and mathematics, at an actuary. Moreover, he was well educated in philosophy of science too. They were very strong fundamentals not only for scientific research, but also to become later the founder of Slovak physics. For Ilkovič's future mission, it was important that he very early met prof. Jaroslav Heyrovský, discoverer of polarography and Nobel Prize winner in chemistry in 1959. Dionýz had joint Heyrovský's group as a young student. He had listened to Heyrovský's lectures. He had worked in practical classes and individual research headed by Heyrovský. Additionally, Ilkovič was deeply influenced by prominent Czech physicist prof. Václav Dolejšek. One can say: in what way was he influenced?

Firstly, chemist Heyrovský and physicist Dolejšek had started in the mid-1920s to organize common seminars, the so-called Chemical-physical dialogues. Current problems of chemistry and physics were discussed there. Dionýz began to attend these dialogues as a third-year student. It was a very important and useful school for him. He became acquainted with the current situation in both physics and chemistry. He also had the opportunity to discuss many problems solved by Heyrovský, Dolejšek and other chemists and physicists at Charles University. Secondly, working at practical classes with Dolejšek Dionýz, he was intensively trained in methods and skills of physical experiments.

Thirdly, Dionyz met two young men at Charles University in Prague in 1925-29: Ján Fischer from Slovakia and Vilém Kunzl from the Czech city of Plzeň. They attended common lectures, seminars and practical classes, and step by step they became friends. During the 1930s Dionýz and Vilém were working at Charles University –Dionýz as an outside assistant of prof. Heyrovský, Vilém as an assistant of prof. Dolejšek. So they knew each other very well.

The 1930s period was very fruitful for Dionýz Ilkovič. He had published about 10 papers in first-rate foreign journals. The most important result was the so-called Ilkovič equation –a basic formula in polarography. Due to this mathematical expression and several other papers, Ilkovič in collaboration with prof. Heyrovský built the theoretical foundations of polarography. In the school year 1937/38 Dionýz Ilkovič made use of Denis' scholarship offered by the French government to gifted Czechoslovak young researchers. Ilkovič was working at the Institute for physical chemistry of Paris University, headed by prof. Audubert. The study of ultraviolet radiation by photoelectric counters was the main theme of Ilkovič's research in Paris. His experiences and findings obtained in the laboratory of prof. Audubert were later used by Dionýz Ilkovič in Bratislava. In the late 1940s he had guided PhD student Štefan Luscoň, who successfully defended his PhD theses on photoelectric cells.

Back again in Prague, Dionýz Ilkovič applied for the veniae docendi. Unfortunately, the process of habilitation was interrupted as a consequence of the closing of Czech universities. This process ended only in 1946.

As mentioned, in the winter semester of 1939/40 prof. Josef Sahánek, head of the Institute of Technical Physics, had left Bratislava, so university authorities called Dionýz Ilkovič for professorship. He accepted such an attractive offer and in February 1940 the president of the Slovak republic appointed him to the post of professor of technical physics and head of the Institute of Technical Physics of the Slovak Technical University. Working there he founded undergraduate study for future physics teachers and future physicists in Slovakia, and started physical research. Dionýz Ilkovič lectured on both theoretical and experimental physics.

From 1939 Slovak young people had no opportunity to study natural sciences or to teach these subjects. So the Faculty of Natural Sciences was established at the Slovak University at October 1940. Dionýz Ilkovič was appointed professor of physics at FNS. Apart from physics, he lectured on chemistry and physical chemistry too. During the 1940/41 school year Ilkovič's sole assistant left Slovak Technical University. Hence, prof. Ilkovič decided to involve several young students as his assistants and mates, first of all Imrich Staríček. That way, he was training, preparing and educating a new generation of Slovak academicians. I would like to say that several of Ilkovič's assistants became later professors as well. At the beginning of the 1950s two of them moved to Košice in eastern Slovakia to constitute the second physical centre in Slovakia.

The very tool for physics and chemistry education at the Faculty of Natural Sciences was Chemical-physical dialogues. In Bratislava they were organized by physicist prof. Ilkovič and chemist prof. Valentín. It was an analogy of the Dialogues organized by prof. Heyrovský and prof. Dolejšek in Prague before World War I. Although the Dialogues were special seminars for researchers, they were included into the students' curriculum, so students had the opportunity to take part in them. As a curiosity we can say that in March 1943 Werner Heisenberg had presented a lecture on atomic physics in the frame of these Dialogues.

In August 1944 the Institute of Physics was established at the Faculty of Natural Sciences. Dionýz Ilkovič had been appointed as its head, so he was heading two institutes simultaneously: the Institute of Technical Physics at Slovak Technical University and the Institute of Physics at Slovak University; Imrich Staríček, his first student auxiliary, was appointed assistant of prof. Ilkovič. In March 1945 Staríček defended his PhD thesis on theoretical physics, and he started to lecture modern subjects of theoretical physics, especially quantum mechanics. From December 1945 he spent one year as visiting researcher at the Radium institute of prof. Iréne Joliot-Curie in Paris.

At that time Ilkovič was very tired of teaching physics and heading two institutes at both Slovak Technical University and Slovak University. He decided to focus his attention only to activities at STU, so he asked Slovak University authorities to invite a new professor of physics for SU. Ilkovič was very familiar with the scientific competence, organizational skills and nice personal qualities of Vilém Kunzl, as he knew him in Prague. Moreover, Ilkovič intended to develop modern branches of experimental physics in Bratislava. Hence, he recommended inviting namely Dr. Kunzl for professorship, member of spectroscopic scientific school of prof. Dolejšek.

Vilém Kunzl completed his education in Prague on experimental physics, teaching of physics and mathematics. Apart from these subjects, he was educated in history and philosophy of science. He was also listening to lectures on physical chemistry presented by prof. Heyrovský. However, he was greatly influenced by prof. Dolejšek, and young Vilém jointed Dolejšek's group interested in spectroscopy.

In 1937 V. Kunzl was habilitated. Between 1930 and 1937 he published 12 papers in various foreign physics journals. It is very interesting and important that his competence for research and lecturing was evaluated by top European spectroscopists –prof. Laue, prof. Paschen and prof. Fajans from Germany and prof. Trillat and prof. Dauvillier from France. All reviewers were satisfied with Kunzl's results in scientific investigation. For example, prof. Laue wrote in his appraisal: "Dr. Kunzl could apply for habilitation at any university in Germany with full success." The habilitation committee noted in its evaluation "the exceptional ability of Dr. Kunzl to improvise in searching for new solutions, to assemble any devices and to set new experiments". It has to be said that all the mentioned qualities will be used by Vilém Kunzl in Bratislava.

The six months which Kunzl spent in Paris in 1939 were important for his future scientific career. He was working in the spectroscopic laboratory of prof. Cotton. Unfortunately, he was forced to return to Prague untimely due to the political situation in Czechoslovakia. He completed his scientific results only in 1947, during his second stay in Paris. He published two papers there.

Coming back to Prague, Kunzl worked at Charles University very shortly, because in November all Czech universities were closed. After that he worked in an aircraft conditioning house up to the end of World War II.

Now we have to go back to Bratislava. As we said, Vilém Kunzl was invited to become professor of physics at the Slovak University at 1946. He accepted this very attractive offer, so owing to Ilkovič's effort V. Kunzl was appointed professor of physics at Comenius University in 1947. In February 1948 he became head of the Institute of Physics of the Slovak University. Scientific activities at the institute were determined by Kunzl's research interests. So vacuum physics, acoustics and ultra-acoustics, X-ray spectroscopy a high-frequency electro-technology was started and developed in the years 1948-52 at the Faculty of Natural Sciences. I would like to pay attention on the fact that these four physics branches are cultivated in our faculty up to now. Vilém Kunz is rightly considered the founder of experimental physics at Comenius University. However, he also contributed to the development of physics at Comenius University in another way: owing to his effort Ján Fischer came to the Faculty of Natural Sciences.

Ján was the third member of a student group which was formed at second half of the 1920s at Charles University in Prague. As his friends Dionýz Ilkovič and Vilém Kunzl, he was educated at the Faculty of Natural Sciences of Charles University. He studied physics and teaching of physics and mathematics, and his attention was focused on theoretical physics. In 1927 he attended a lecture on quantum mechanics, and another one on the Compton effect in 1928. Both lectures were presented by Viktor Trkal. As Ján was a very gifted theorist, he was recommended by prof. Záviška for PhD study at the University of Zürich. In 1928-31 he completed his PhD study under supervisor prof. Gregor Wentzel. In Zürich J. Fischer completed two papers in which he picked up the threads of Wentzel's work on quantum-mechanics description of Compton effect and photo effect. Fischer had developed a new method to describe these effects in more detail. One can say that his mathematical description concerning the process of absorption in language of quantum mechanics was complete. Thanks to it Fischer's papers became foundation stones of quantum theory of interaction between radiation and matter, so we can consider Ján Fischer as the first Slovak theorist.

Coming back to Prague, Fischer intended to work at Charles University. Unfortunately, at that time he had no opportunity to become an assistant at the Institute of Theoretical Physics. Moreover, he was taken ill with tuberculosis, so he moved back to Slovakia. After pulling through and recovering, Ján started to teach physics and mathematics at various Slovak secondary schools. Only after World War II did he go to Bratislava. In 1950, owing to efforts by Vilém Kunzl, Ján Fischer was appointed assistant professor at the Faculty of Natural Sciences of the Slovak University. When prof. Kunzl came back to Prague in 1953, Ján Fischer took over administration of the Department of Physics. It was divided in 1961 and prof. Fischer became head of the Department of Theoretical Physics. He administrated it between 1961 and 1975, and created very suitable conditions for forming Bratislava's school in theory of elementary particle.

To sum up, Dionýz Ilkovič founded undergraduate study for future physics teachers and future physicists at both Slovak University and Slovak Technical University of Bratislava. He started physical research in Slovakia. First his followers moved to Košice at the beginning of the 1950s and founded a second centre of physics. Vilém Kunzl started and developed four physics branches at the Faculty of Natural Sciences, which are cultivated there up to now. Vilém Kunz is considered a founder of experimental physics at Comenius University. Ján Fischer became the first Slovak theorist and founder of theoretical physics in Bratislava.

No doubt, D. Ilkovič, J. Fischer, and V. Kunzl could become founders of Slovak physics, mainly owing to their high-quality training at Charles University in Prague. Moreover, creating the new branch of science, seeking its orientation, forming undergraduate training of future physics teachers and physicists, they used fairly all their experience, methods, opinions, and ideas which they met in Prague. Many of their scholars moved from Bratislava to other Slovak cities to find new physical centres.

The development of physics in Slovakia was affected by Vienna University too. As prof. Ilkovič was not interested in quantum mechanics, he recommended Imrich Staríček for study of quantum mechanics and other modern branches of physics in the University of Vienna. Returning to Bratislava, Staríček started lecturing a course of quantum mechanics at Comenius University. I. Staríček begun in 1951 to collaborate with Dr. Václav Votruba, professor of theoretical physics at Charles University in Prague. Votruba had studied (1945-47) at ETH Zürich under supervisor prof. Wolfgang Pauli. After coming back home, he started cultivating elementary particle theory in Czechoslovakia. Unfortunately, collaboration between Staríček and prof. Votruba was ended very soon, as I. Staríček was arrested by the communist police for fictitious espionage and committed to prison for ten years.

For this reason, prof. Votruba continued to lecture quantum mechanics in Bratislava. During his lectures, he paid attention to the gifted student Milan Petráš. In such way collaboration between prof. Votruba and Milan Petráš started. Václav Votruba gave young Milan directions for his diploma thesis and recommended him to specialize in elementary particles theory. Between 1952 and 1955 Milan Petráš, a student of Comenius University, completed his PhD study in Charles University under supervisor V. Votruba. Returning to Bratislava, M. Petráš continued his investigation, and step by step he created Bratislava's school in elementary particles theory. It is not an exaggeration to say that an overwhelming majority of Slovak theoreticians who were or are interested in elementary particle theory are Petráš's scholars –either directly or indirectly. Clearly prof. Votruba vicariously contributed to such success.

Conclusion

As we said at the beginning, the formation of Slovak physics is a pregnant example of the importance of idea circulation. All founders of Slovak physics –Ilkovič, Kunzl, Fischer, Staríček and Petráš– were educated in Prague or in Vienna. Moreover, Ilkovič, Kunzl and Staríček were developing their physical competence in Paris, Fischer in Zürich, Petráš in the Joint Institute of Nuclear Research at Dubna. Returning to Bratislava they all used experiences gained outside Comenius University in educating many generations of Slovak physicists and physics teachers. We have to thank them for their efforts.

THE INVENTIONS OF JOSÉ RUIZ-CASTIZO: THE PLANIMETER

Claudia VELA URREGO, Mª Ángeles MARTÍNEZ GARCÍA
Universidad de La Rioja, Logroño, SPAIN
claudia-teresa.vela@alumn.unirioja.es
angeles.martinez@unirioja.es

Abstract

The aim of this work is to describe the invention of a planimeter by the Spanish physicist-mathematician José Ruiz-Castizo Ariza (1857-1929). He was a professor of Mecánica Racional *in the Universities of Zaragoza (1896-1905) and Madrid (1905-1929). Before getting his chair, being assistant professor of* Física Superior *in the Faculty of Sciences in Madrid (1892-1896), he invented a planimeter the analytical basis of which was different from others known then. During his first years in Zaragoza, he published an extensive article explaining the theoretical foundations and the phases followed in its design, from the first prototype to the final result. Ruiz-Castizo's planimeter, which ameliorated the performance qualities of the ones by foreign authors that were being used in Spain, was built in Switzerland in 1897, tested in the Public Works Office (*Oficina de Obras Públicas*) in Zaragoza and used in other technical Offices, including the local delegations of the National Geographic Institute (*Instituto Geográfico Nacional*).*

José Ruiz-Castizo y Ariza (1857-1929)

Ruiz-Castizo was born in Fuentes de Andalucía (Sevilla), and attended High School in the *Instituto provincial de Sevilla*, where he graduated in 1876 with excellent qualifications. He started a degree in Mathematics in this town and finished it in the Central University in Madrid in 1881, taking the doctor's degree in 1887.

Afterwards he started, in the capital too, an academic life with the following jobs: Assistant in the General Preparatory School for Engineers and Architects (1888-1892), Assistant of *Física Superior* in the Faculty of Sciences (1892-1896) and Auxiliary professor in the Physic-Mathematical Section in the same institution (1889-1896). Since March 1896, he was Professor of *Mecánica Racional* in the University of Zaragoza and at the same time he taught *Elementos de Física* in the Arts and Crafts School (*Escuela de Artes y Oficios*). Up to 1905 he completed his academic life as Professor of *Mecánica Racional* in Madrid, where he died. Ruiz-Castizo was member of the *Ateneo of Madrid* since 1891, and elected member of Royal Academy of Sciences in December 9, 1914, without ever taking possession.

Fig. 1: A photograph of Ruiz Castizo[1]

During this teaching time, he published in physics, mathematics and disclosure issues in several journals, and also, some monographs and books such as[2]:

Articles in journals:

- *La Naturaleza:* La electróptica y las ideas de Maxwell, El centro de gravedad, 1895.
- *Revista de la Real Academia de las Ciencias:* Los principios fundamentales de la Mecánica racional. Un primer capitulo de la dinámica, 1909.
- *Revista Trimestral de Matemáticas:* Algunas fórmulas para el empleo de ejes coordenados oblicuos en la Mecánica analítica, 1903; Sobre las hipótesis que sirven de fundamento a la Mecánica Racional, 1903; Nota sobre una propiedad de las formas cuadráticas, 1904; Resolución algebraica de la ecuación de cuarto grado, 1905.
- *Revista Matemática Hispano-Americana:* Prontuario de las cúbicas planas, 1925.

Books

- *Estudio analítico de un lugar geométrico de cuarto orden*, Madrid 1889.
- *El Eclipse total de sol de 1905* (with Gabriel Galán), Zaragoza 1905.
- *Tratado de Mecánica Racional*, Madrid 1907-08.

It's interesting his facet as inventor. His most important invention is the planimeter, the object of this article, but at least we want to mention a regulating mechanism for vapour machines (1919)[3] and a transmission through gears (1920)[4].

Planimeters

During the first half of the 19th century, it was necessary for an instrument to measure with precision an area represented in a plane. This need inspired several ingenious devices. Planimeters are apparatus that allow to measure areas enclosed by plane curves having the integral calculus as its theoretical basis. Various scientists invested time and effort to the design, construction and improvement of these instruments.

---

2 We don't include publications referred to the planimeter because they will be cited along the text and also, in the references at end of the article.

3 *Boletín Oficial de la Propiedad Industrial*, November 16, 1919.

4 Proyectos de aparatos: año de 1928. Carp. 15. Instituto del Material Científico, CSIC.

Johann M. Hermann invented the first planimeter in 1814, which was improved by Lämmle in 1816 and built in 1817. The Swiss engineer Johannes Oppikofer invented another planimeter in 1826, which was built in 1834 by M. Ernst in Paris. As the Hermann planimeter, the design is based on a cone that rotates on an axis, which supports a wheel that rotates with it. In 1849, Kaspar Wetli invented another one that was built by Georg Christoph Starke.

But the planimeter that involved an essential change, in relation to the design and concept of these machines, was the one invented by the Swiss mathematician Jakob Amsler-Laffon (1823-1912). It is considered to be the first modern planimeter. It was built in 1854 and has two variants: polar and lineal. The polar planimeter is composed of two articulated arms. One of them has the unarticulated end fixed, so the articulation point moves along a circle. In the lineal planimeter, this last point moves along a straight slot.

An atypical planimeter was the one designed in 1875 by Holder Prytz (1848-1930), mathematician and Danish cavalry officer. It was made in Denmark in 1887. It had a simple design, but the precision of its measures was limited[5].

Interest in Spain by planimeters is evidenced by the publication in the journal *Revista de Obras Públicas*[6] of the description and use of several of them (Amsler, Wetli and Starke, Duprez) between 1861 and 1872. Ruiz-Castizo took these planimeters as reference and proposed to improve its performance in several aspects, which he finally achieved after a process of successive improvements from a novel theoretical basis.

Ruiz-Castizo's planimeter

When Ruiz-Castizo started publishing articles about his planimeter in 1896, he was already testing a prototype that he had patented with the name "Planímetro é integrador cartesiano de evaluación tangencial" in August 21, 1895. This patent expired in December 11, 1897 in order not to pay the second annual payment. The reason was that he had filed a new patent application for his final model of "planímetro e integrador tangencial", which was granted on December 18, 1897. Moreover, in order to push forward its innovative project of planimeter, Ruiz-Castizo sought the support of the Royal Academy of Sciences , which issued favourable reports in 1896 and 1898 for each of the successive models.[7]

The author published the "principio analítico" or the mathematical basis of his planimeter in the journal *La Naturaleza*, in which number of June 18, 1896 appeared a short article [2]. Ruiz-Castizo considers a curve $y=f(x)$, a point on it varying M, P the projection of M on the horizontal axis (Fig. 2)[8] and MQ a line whose distance to P is constant and equal to a; then he shows that the envelope of the family of straight lines MQ is "una verdadera cuadratriz del area comprendida entre la curva $y=f(x)$ y el eje de las x", ie, that the ordinates that are limiting the area enclosed by $y=f(x)$ and the axis x , intercept an arc in the envelope curve, whose length multiplied by a is equal to this area.

Indeed, if (x,y) are the coordinates of M, the family of straight lines MQ (with slope μ) has as equation $Y–f(x)=m(X–x)$, being $m=\mathrm{tg}\mu$, $\cos\mu=a/y$, so the differential arc length of the envelope curve is $ds=(1+m^2)^{½}dx=(y/a)dx$ and then $A=aL$, where A is the area under the initial curve and L is the length of the envelope between the same abscissas.

Fig. 2 shows that the envelope proposed by Ruiz-Castizo is for a family *NN'* parallel to *MQ*, *N'N''* parallel to *M'Q'*, etc., all them with the same vertical displacement, which is an envelope moved vertically of the previous one therefore with the same length between points with the same abscissas. When he raised the problem with this vertical displacement, he was thinking in the practical use of this analytical principle, because he knew, and so he writes, that the envelope curve can be drawn and measured with great accuracy through a kinematic combination, not difficult to get. Also, the previous analytic relationship gave rise to a new mechanical integrator, a subject that he began to develop at the end of that same year in a journal with wider spread[9], when he had already got a favourable report from the Royal Academy of Sciences.

At the end of 1896, the first appeared of the six parts in which Ruiz-Castizo divided the article titled "Un Nuevo planímetro", published over more than a year in the *ROP* [5]. The second one took nearly a year to appear, which happened immediately after the author sent, in September 26, 1897, the second request for the report to the Royal Academy of Sciences. Thereafter the parts were approximately monthly until the end of the article. In this work, besides repeating the theoretical foundations developed in *La Naturaleza*, he explains the design and construction of the planimeter in various phases, the first of which was already in trial operation. The chronological scheme of successive deliveries can be seen in Table 1.

---

[5] You can see a historical outline about these planimeters in [6] and [7, ch. 9].

[6] From now on, we'll refer to this journal as *ROP*.

[7] See *Anuario* of the Royal Academy of Sciences, 1896. The second report is included in the memoir [5].

[8] See [3, p. 271].

[9] He published in *La Naturaleza* a second article on the planimeter [3], but its information is contained in the one published in *ROP* we are going to discuss.

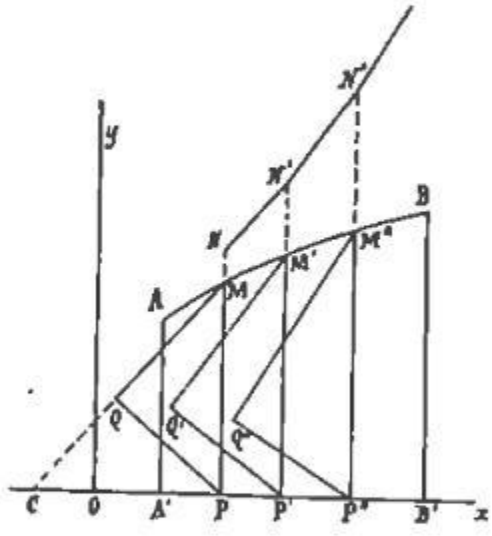

Fig. 2: Generation of the "cuadratriz" (envelope curve).

Table 1: Chronology of the successive deliveries of the article "Un Nuevo planímetro".

	Original date	Published	Content
1	11/1896	5/11/1896	Proof of the "Principio analítico". Schematic-theoretical description
2	07/1897	30/09/1897	Discussion of the model. Kinematic questions. Inclination of appraising wheel
3	08/1897	28/10/1897	Guiding reciprocating mechanism: articulated parallelogram and gear system
4	12/1897	23/12/1897	Two prototypes: parallelogram and wheel
5	01/1898	27/01/1898	The final model
6	01/1898	24/02/1898	The "integrómetro general"

We describe now the contents of each part:

1. The author begins by highlighting the practical importance of planimeters, but he argues that their results are somewhat insecure, so that to choose a trustworthy planimeter is a trouble. Then, he justifies his proposal for a new instrument which provides no little interest because it has an analytical principle totally different from those that have so far been used, reducing the problem of squaring an area to the rectification of a well-defined curve. Then he exposes the analytical principle repeating what he has already published in *La Naturaleza* a few months earlier. The new thing he shows now, with a graph (Fig. 3) as above (Fig. 2), is a first sketch of the instrument, referred to as "descripción *teórico-esquemática*", that embodies the theoretical explanation, so *YDD'* corresponds to *PQM*.

The instrument consists of two rules, *XX'*, *YY'* plus a square *YDD'* with right angle at *D*. The rule *YY'* moves perpendicularly to *XX'*, which is fixed. The end Y of the square moves on *XX'* at the same time as *YY',* and the square has also a movement inside the slide *M,* when this moves along *YY'*. The slide *M* carries a pointer to be moved along the given curve. Another slide *R* is moved on *YY'* connected to *M* by a mechanism that forces *R* to move in the direction *DD'*, describing the envelope by a wheel whose rotation is recorded to measure its length, equal to the area of the curve given. Ruiz-Castizo finishes explaining that an appropriate mechanism will transmit the movement of the square *YDD'*, when the pointer located in *M* moves along the curve given, to the slide *R* in which the wheel will move without slipping on the role, because of its suitable inclination. After this general idea, Ruiz-Castizo postpones until the following parts other details of the instrument and the results obtained with the already made models. The photograph of one of them, which regulates the movement of the square with an articulated parallelogram, appears in the first page of the article, although its description will be undertaken in the fourth part.

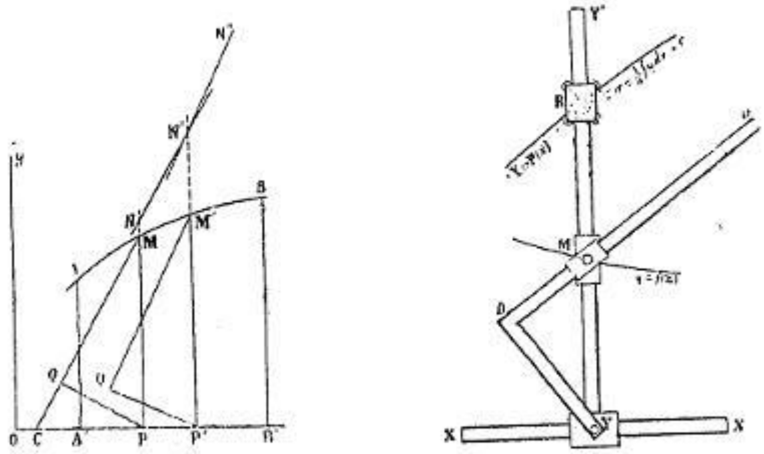

Fig. 3: Graph and sketch of the planimeter.

2. The author explains that in his first request to the Royal Academy of Sciences, he named the instrument as "*planímetro cartesiano de valuación tangencial*", a name inspired by the wheel on *R* which moves tangentially to the envelope curve. Afterwards he emphasizes the great simplicity of his theory, which considers very important. He believes that the easier the theoretical principle is, the easier it will be also to permanently check its regular working.

In the three examples in Fig. 4, the shape of the "cuadratrices" are shown depending on the complexity of the curve limiting the area. To the left, you get the area under the curve through two discontinuous arcs, requiring a shift of planimeter to allow the pointer to go through the whole curve. In the centre, the envelopes for a closed curve with a very regular form. When the planimeter moves along the arc *ACB*, the envelope *αβ* is generated, and along *BDA*, the appraising wheel rotates in the opposite direction giving the envelope *βα'*. So the counter will provide, by the difference between the lengths of the sections, the area enclosed by the curve *ACBD*. To the right, an irregular closed curve's area can be obtained by the algebraic sum of several arcs of envelope.

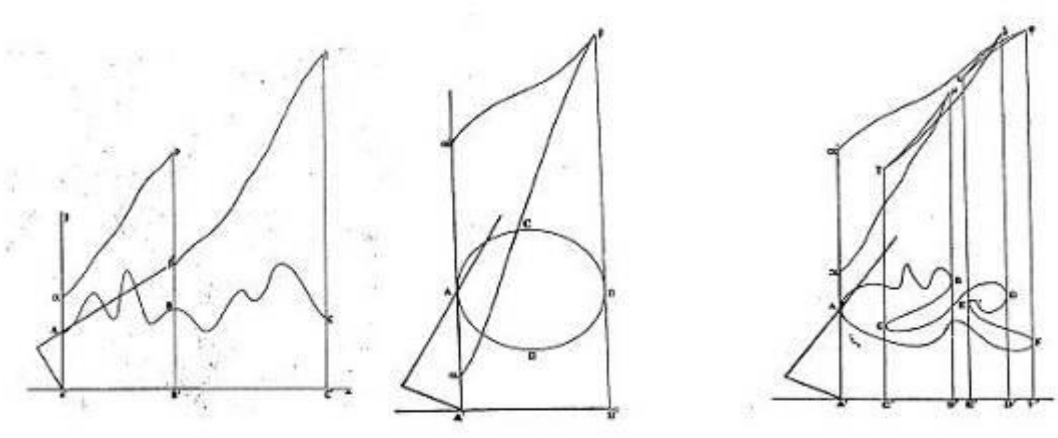

Fig. 4: Examples of curves with their envelopes.

The author notes that in making these operations it may be necessary to move the planimeter to complete the figure, which represents a reduction of time, work and possible errors in relation to other ones used. Another interesting quality is that the accuracy of his instrument can be checked *a posteriori* because it also draws the envelope curve, i.e., it's an "intégrafo" and no other has this quality. He considers this opportunity of rectification important, because its movements were not completely sure and could cause "errores accidentales de importancia". This observation gives him the opportunity to explain that the device is easy to make in the workshops and its perfect operation depends on two aspects: the friction and the appropriate mechanisms to convey the proper orientation to the appraising wheel located in *R*. Ruiz-Castizo proceeds to a technical study, kinematic and dynamic, of these aspects, noting in conclusion that the maximum tilt of the wheel admissible in practice will mainly depend on the base material on which this one is supported and the degree of sharpening of its edge.

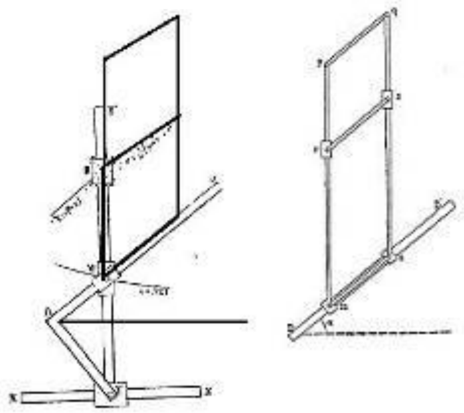

Fig. 5: The articulated parallelogram.[10]

3. Ruiz-Castizo focuses the third part to explain the mechanism to ensure that the inclination of the axis *DD'* coincides with the appraising wheel's, located in *R,* regardless of the distance between both elements. After calculating the errors that can be made by mismatches at this angle, he proposes and studies two modes of transmission, "un paralelogramo articulado, ó un juego de engranajes", to choose depending on the angle of rotation. He explains the parallelogram method around the Fig. 5 and concludes its good efficiency for amplitudes of rotation smaller than $\pi/2$, assuming a careful construction of the apparatus. He says he already has two prototypes with this system, but postpones their description for the next part. He devotes the end of this part to describe the gear set, although this time he has ruled out this system.

4. The planimeters appear at the end of the fourth part. Their photographs are exhibited and Ruiz-Castizo makes a detailed description of each element and of its functioning, starting with the one shown in Fig. 6.

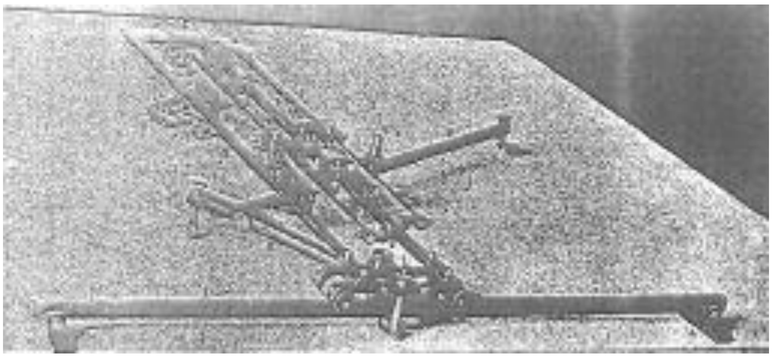

Fig. 6: First prototype.[11]

Ruiz-Castizo recognizes that the planimeter was made in Madrid by two technicians with limited technical recourses. Then, although he supervised it piece by piece, it had manufacturing defects that produced significant errors. But even properly made, he also indicated that it would work accurately, but was still uncomfortable in its practical use. There were some problems, for example, with the type of paper to use so that the wheel recorded the envelope curve without damaging it. Also, there were practical drawbacks of some importance, such as the movement range of the mechanism, that could cause the drawing of too many partial arcs to certain "cuadratrices" or an inconvenient access to the counter.

---

[10] The right figure is in the article; the left one has been added to indicate its placement on the general sketch of the planimeter.

[11] See: [5, 1897, nº 1161, p. 671]

While the previous model was being built, the inventor contacted the *Société Genevoise pour la construction d'Instruments de Physique et de Mathématiques*, and came to introduce a simplification that produced an important progress. The square set was replaced by a wheel, whose radius was equal to the base of integration as shown in Fig. 7, with a rod permanently resting on it and passing through the point where the punch was located.

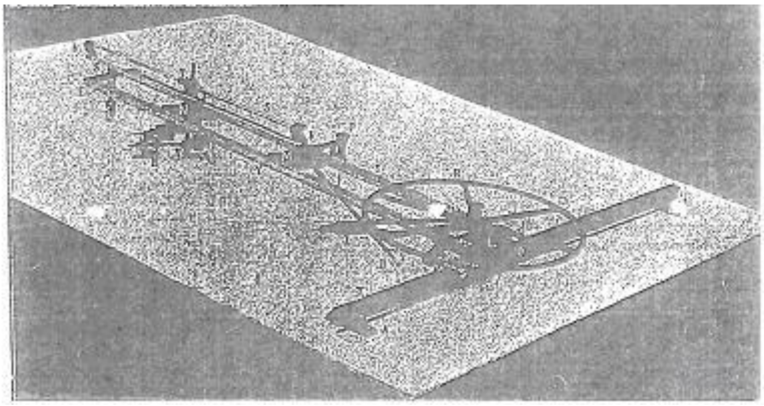

Fig. 7: Second prototype.[12]

With this change, the instrument movement became softer and had a much more satisfactory performance, with very accurate results "por defecto siempre". But the practical management problems, already mentioned for the previous model, persisted. So he addressed a final reform of the instrument which led him to change the details of its construction. Ruiz-Castizo says that this new model, already built by the *Société Genevoise* and tested by the staff of the Public Works offices in Zaragoza, has satisfied the most demanding expectations. The author leaves for following delivery a detailed description of this brilliant final model.

Before concluding, we note that Ruiz-Castizo had recognized in this part that his article consisted, in the first fourth parts, of "algo así como una sucinta historia de mis trabajos, un archivo, diríamos, del proceso de mi humilde creación", i.e. the article was a summary of the process that led him to the final model.

5. In this fifth part, Ruiz-Castizo presents the final model of the planimeter, which successfully completes the process begun years ago. With the photograph of the instrument, Ruiz-Castizo makes its description in detail, including the kinematic mechanisms and the one that ensures the prospered orientation of the appraising wheel any time. The inventor highlights that the fundamental change introduced is to draw the envelope curve on a cylinder instead of the picture plane. He chose boxwood for the cylinder.

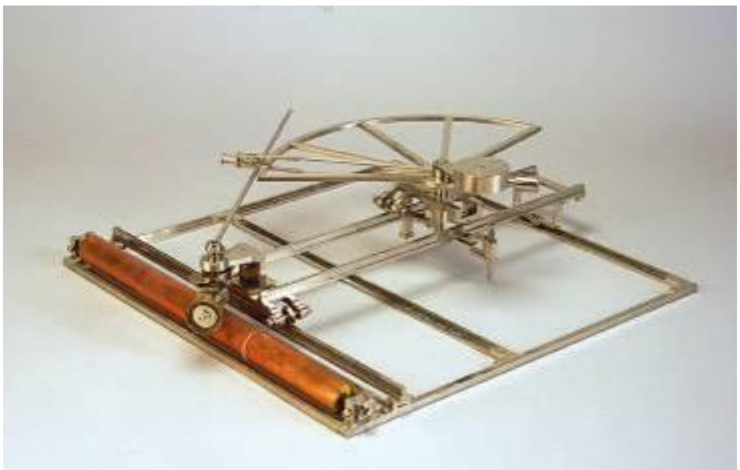

Fig. 8: Ruiz-Castizo's planimeter.[13]

[12] See: [5, 1897, nº 1161, p. 671]

He describes the main dimensions of the instrument and the whole amplitude of its movements. Then, he goes on to considerate the numerous advantages achieved with this new planimeter and to give precise data about its high precision: “Es lícito ya sentar que ofrece excelentes condiciones como mamuable, expedito, seguro y exacto”.

Finally, Ruiz-Castizo says that his instrument had been supported by the Public works staff (that already examined his first model), other technical agencies in Zaragoza[14] and professors. Also, he adds that the *Inspección del Canal Imperial* and the *Jefatura provincial de Obras Públicas* had acquired several copies.

Thus, Ruiz-Castizo managed to put on the market an instrument of national design and Swiss manufacture which competed advantageously with other imported planimeters.

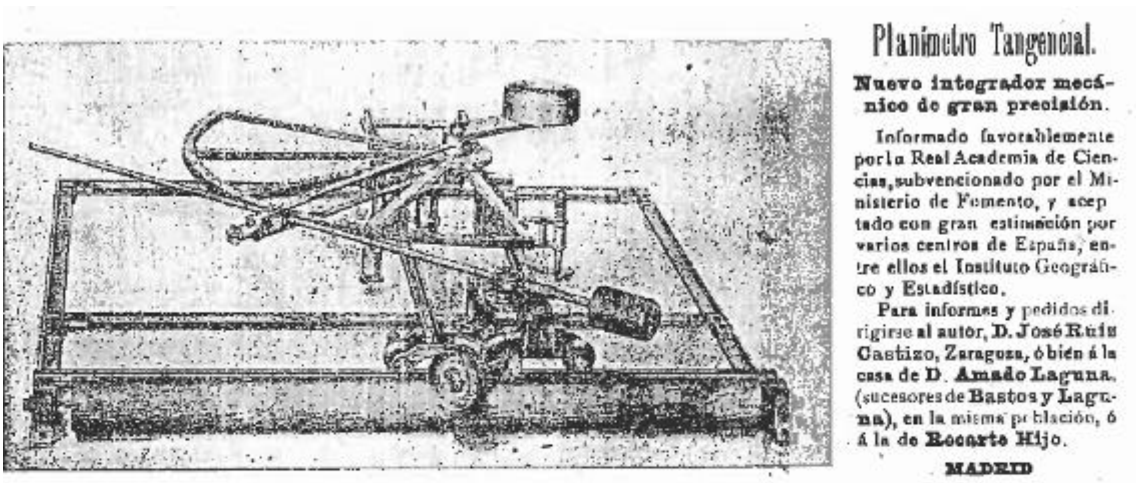

Fig. 9: Advert published in *La Naturaleza*, October 8, 1903.

6. The final part refers to a new instrument that, based on the planimeter, extends its functions to be an “integrador applicable a los tres órdenes”, that can calculate the typical integrals of the planimeter, $\int ydx$, and the ones of second and third order: $\int y2dx$, $\int y3dx$. Ruiz-Castizo adds that this new planimeter has not been built yet, therefore the current work is rather a memoir or a draft of it where critical comments could be made about its construction and applications in the future. For this reason, and to limit the extent of our work, now we confine ourselves to the image of the instrument (not complete) that he introduced to give a graphic idea of its composition.

That same year (1898), he published a memoir [5] that presents the integrator, and, as a particular case, the planimeter, reproducing the contents of *ROP*, with different organization in the text except in its historical parts.

UNSUCCESSFUL TRANSMISSION OF KNOWLEDGE. AN EXAMPLE OF THE ASTRONOMICAL SOCIETY OF INDIA

Rajinder SINGH
Research Group – Physics Didactics and History of Science,
Institute for Physics, Faculty V, Universität Oldenburg, GERMANY
rajinder.singh@uni-oldenburg.de

Abstract

After some parts of Indian territories came under the British East India Company, in 1784 William Jones from Oxford founded the Asiatic Society of Bengal *in Calcutta. In the following years the Society was immensely successful in spawning a network of scientific organisations and institutions like the Royal Botanical Garden, the Indian Museum, the Meteorological Department of the Government of India and the Medical College of Bengal. So far the astronomical research based on the "western methods" were concerned, the East India Company established an observatory at Madras for promoting the knowledge of astronomy, geography and navigation. The building for the observatory was completed by 1792. Institutions like the Asiatic Society and Madras Observatory (founded in 1879) played a crucial role for the transmission of knowledge from West to East and vice versa. Contrary to them the Astronomical Society of India (founded in 1910) failed. The present communication speculates about the reasons behind the failure in social and cultural context.*

Introduction

The *National Geographical News* on September 19, 2010 reported that *"India unveils world's highest observatory – The latest hot spot for international astronomers is perched on a lonely peak in the western Himalayas."*[1] Today India possesses 16 observatories and belongs to nations taking active part in astronomical researches.[2] She has the Astronomical

Shukla, Indian National Science Academy, New Delhi (1985). R. Kochhar, J. Narlikar, *Astronomy in India: A Perspective*, Indian National Science Academy, New Delhi (1995).

Society of India (established in 1972).[3] The less known fact is that already in 1910 the Astronomical Society of India (henceforth ASI) was founded. After more than a decade it died its own death. In the following paragraphs a short history of the activities of the ASI and reasons behind its "disappearance" are discussed.

The Astronomical Society of India and its activities

In April-May, 1910 the famous Halley's Comet was observed in India (see Figure 1). It evoked interest of the general public in astronomy. Consequently it led to the foundation of the Astronomical Society of India.[4]

Fig. 1: Halley's Comet photographed at Kodai Kanal Observatory on 3rd May 1910.

Archive – Indian Institute of Astrophysics, Bangalore.

The main objective of the ASI was to foster interest in general and practical astronomy. For this purpose, it took various steps like the following:

- In order to be informed about the international researches in the field, the Society subscribed journals from the Royal Astronomical Society of London, the Astronomical Society of Italy, the Royal Observatory of Belgium, Paris Observatory and others.
- The Journal of the Astronomical Society of India was started. In it the annual/monthly meetings reports, popular and general lectures, scientific papers and notes of the Society were published.
- The Society bought instruments from abroad. For astronomical observations the Society's Observatory installed an 8.5-inch telescope, which was housed at the roof of the Treasury Buildings.
- To acquaint the members with the methods of observations, practical classes were held.
- During the meetings, the members were informed about the construction of a cheap telescope and the erection of an observatory.

[4] For more details about the foundation and activities of the Astronomical Society of India, see, R. Singh, 'The 100th anniversary of the Astronomical Society of India', *Science and Culture* (forthcoming).

- To motivate the students, a prize for the best essay was initiated.
- Popular lectures were organised by the society.

Astronomy –a field without perspectives

The causes for the disappearance of the society were as follows:

- In general, when a new organization is started the motivation is high. It fades away as time passes, if its members and supporters do not get any benefit. At the *Annual Meeting of the Society* in November 17, 1919 in the Presidential address it was pointed out that most of the members had their own profession (such as Bank officer or clerk) to have any opportunity for carrying out original investigations. Thus interested members could not adopt astronomy as their profession.
- India lacked the class of amateur which had made England famous in science, as was once said by the President of the ASI.[5]
- The East India Company, for promoting the knowledge of astronomy, geography and navigation in India, established the Kodaikanal Observatory in 1879.[6] According to the author D.C.V. Mallik, *"The Government of India had supported the work in the belief that a study of the Sun would help in the prediction of the monsoons, their success and failure, the latter often leading to famines that caused such a havoc. The Solar Physics Committee also suggested to the Surveyor-General, Government of India 'that photographs of the Sun should be taken frequently in order that India might assist changes in the solar surface'."*[7] In the following years the observatory played an important role for the study of stars, and in particular the sun. These observations were important for the colonial rulers as the knowledge won there could be used for sailing purposes.[8] This was contrary to the ASI and its work, thus not much importance was given to it.
- As far as climatic and geographical conditions were concerned, Calcutta was not suitable for astronomical observations as its geographical position is little raised from the sea-level. Also vapour-laden atmosphere, sooty vapours poured forth from an ever-increasing number of chimneys, the glare from the city lights made the observations difficult.[9]
- In the West astronomy boomed with the discovery of the telescope in the 17th century. In the following years a number of telescopes were built. In general the making of scientific instruments was accepted as a profession. In India glass as the backbone of optical instruments did not enjoy a social status similar to that of metals and pottery, which were preferred to glass vessels, especially on religious occasions. No doubt the Indian craftsmen mastered the glass technology, but the society accepted it only for decoration and ornaments.[10] Apart from that a caste ridden society made it impossible that a glass-maker worked together with a metal-specialist. For generations a profession was practiced by families. A French writer, Jean Baptist Tavernier, once observed as follows *"A goldsmith would not work in silver, nor a silversmith in gold. In the looms, a weaver would weave only one single sort of stuff during the whole life, unless he was compelled to take another in hand."*[11] Obviously, making a telescope by local workers was not an easy task. The only alternative was to import expensive instruments from abroad.[12] Some of the active members of the ASI like C.V. Raman (who in 1928 along with his student K.S. Krishnan discovered the effect named after him, and in

1930 won the physics Nobel Prize[13]), though very much interested in the subject, put aside his astronomical researches as he could not afford proper instruments.[14]

- In the *Annual Report* for the Year 1919-1920 the financial position was called satisfactory by the Business Secretary.[15] In general the rich community of Calcutta was less interested in astronomy as compared to physics and chemistry. For instance, in the 1910s Palit Professorships were created at the University of Calcutta with huge donations. None came forward to spend such a huge amount on astronomical researches.

The Astronomical Society of India did not produce any scientific research of international level. Almost within a few years, its name disappeared from the memories of prominent physicists like M.N. Saha, who delivered popular lectures at the Society. At the 25th anniversary of the Indian Science Congress, Saha wrote on the *"Progress in physics in India during the past twenty-five years"*. He reported the work done in various fields of physics including astronomy and astrophysics. He did not mention the name of the Astronomical Society of India.[16] In 1948 Raman gave popular lectures in which he did not mention about his activities within the ASI.[17]

Concluding remarks

- The modern policy makers, in particular in the field of international politics, may learn from the history of the Astronomical Society of India that the transmission of knowledge might not be successful if the local community is devoid of either financial or scientific or technological benefits.
- Before starting a project, it is necessary to make a geographical analysis of the place, taking for instance the projects related to wind and solar energy.

DAYTON C. MILLER'S ETHER-DRIFT EXPERIMENTS

Roberto LALLI
Dipartimento di Fisica, Università degli Studi di Milano, ITALY
roberto.lalli@unimi.it

Abstract

One of the most important cases of circulation of a physical idea in first half of the 20th Century concerns the relativity theory. Miller's experiments and their international reception are an example of how the circulation of relativity theory and some physicists changed the scientific research programmes.
Between 1902 and 1926, Miller made several ether-drift experiments similar to the well-known 1887 Michelson-Morley one. The 1920s Miller's experiments, on the contrary to Michelson-Morley's ones, showed a periodic second-order effect that he interpreted as a proof of the absolute motion of the Earth. Since the fringes shift he measured corresponded to a velocity of the Earth lower than the one expected in a fixed-ether theory, he developed a theory of absolute motion of the Solar System and published it in 1933.
He thought that his results disproved the theory of relativity, but most of the international scientific community did not believe him and preferred a different explanation, like temperature variations, wrong data analysis, experimental errors, etc. After Miller's claims, the Michelson-Morley experiment was repeated many times from 1926 to 1930 by other experimenters with different instruments. All these experiments gave a null result.
In 1955, Shankland and his co-workers explained Miller's data as depending on temperature variations, in the context of the relativistic research program.
My study has the aim to broaden the understanding of what happened between 1925 and 1955:

1) Knowledge and interpretation of Miller's data inside the international physics community;
2) If there was a controversy inside American or European scientific communities;
3) The relation between Dayton C. Miller and other American or European physicists.

The themes I am willing to analyze are important in developing the history of relativity, in particular the history of the reception and circulation of relativity in the American scientific community.

Introduction

In 1925 Dayton C. Miller announced that his repetitions of the Michelson-Morley experiment had shown an effect corresponding to an ether wind of about 10km/s.[1] This finding was the most acknowledged fact in contradiction with special

[1] Miller summarized all his work about these ether-drift experiments in D. C. Miller, "The Ether-Drift Experiment and the Determination of the Absolute Motion of the Earth", *Reviews of Modern Physics*, 5 (1933): 203-42.

relativity theory during the 1920s. A minority of scientists are still claiming that this discovery was fundamental and that it was discarded without an acceptable explanation.[2] This communication has the purpose to analyse some features of the US reaction to Miller's announcement, which has not found an adequate study in historiographical descriptions of the events.

It could be useful to begin with a short chronology of the principal events linked to the MM experiments before Miller's claims. With the name "MM experiment" I mean the kind of experiment that was conceived and realized by Albert A. Michelson in 1881 in Potsdam. He observed a null effect and affirmed that it was in accord with the Stokes' ether theory, that is an ether that was totally dragged by the earth near its surface.[3]

In 1886 Michelson, with the help of Morley, confirmed the result of the Fizeau experiment and, one year later, confirmed the null result of the MM experiment. The conclusion of the 1887 paper was that no ether theory could explain both these experiments.[4]

In 1892, Lorentz found a possible theoretical solution that could account for the null result of the MM experiment. He hypothesized a contraction of the bodies in motion in a stationary ether in a way dependent on their velocity in a stationary ether: the so called Lorentz-Fitzgerald contraction.[5]

In the period between 1902 and 1906 Morley, with the help of his new colleague Miller, repeated the MM experiment in Cleveland and at the Euclid Heights with the aim of discovering if the Lorentz-Fitzgerald contraction was different for various materials. Here again the published conclusion was that these experiments confirmed the null result.[6]

In the same period, Einstein published his famous paper about the so called special relativity theory. This theory is in agreement with the null result of the MM experiment and, above all, Einstein clearly proposed the dismissal of the ether with the sentence: "*Die Einführung eines 'Lichtäthers' wird sich insofern* […] *überflüssig erweisen*".[7]

Between 1907 and 1915 Einstein developed the theory of general relativity, whose final structure was exposed in November 1915, during the First World War. A few months after the end of the War, in November 1919, Eddington claimed that the photos of the stars around the sun, which were made by the British eclipse expedition, confirmed the prediction of general relativity theory. Eddington's announcement was accompanied by an enormous press campaign that gave Einstein and his theory an immediate fame all around the world.[8]

Between 1906 and 1920 Miller became and expert of acoustics and did not repeat the MM experiment. Only after Eddington's announcement Miller decided to repeat the MM experiment since, in his words, "the Theory of Relativity postulates an exact null effect from the ether-drift experiment which had never obtained in fact".[9]

[9] Miller (note 1), p. 217. Douglas L. Darnell, who was a student of Miller, stated that *"[Miller] said that Einstein had based his theory on incomplete experimental data and that he would have to get busy and complete the aether-drift"*. Darnell to Shankland, 10 April 1963, Cleveland, *Case Western Reserve University* (*CWRU*) Archives, Robert S. Shankland Papers (RSP), A 08-19, box 1.

He performed these new repetitions at the top of Mount Wilson (one thousand seven hundred meters above sea level) thanks to the hospitality of the *Mount Wilson Observatory* (MWO)and its directors G. E. Hale (between 1904 and 1923) and W. S. Adams (1923-46).

After the first observations (April and December 1921) Miller was not sure about the result since the effect he observed was very slight. But in 1925 he eventually announced that his latest observations at Mount Wilson showed a real ether-drift effect in two US scientific meetings: the April meeting of the *National Academy of Sciences* (NAS) and the December joint meeting of the *American Physical Society* (APS) and of the *American Association for the Advancement of Science* (AAAS).

Miller maintained his conviction for all his life and, in 1933, he published a long paper in which he summarized all his works about the MM experiment and repeated his strong previous conclusion: “These observations all show a positive periodic displacement of the interference fringes as of an ether-drift, of the same magnitude, about 10 kilometers per second […]. The effects were shown to be real and systematic, beyond any further question”.[10]

After Miller had announced his positive result many physicists began to plan a repetition of the MM experiment in the USA as well as in Europe with the specific purpose to test Miller’s conclusion. These experiments were performed between 1926 and 1930 and no one showed the same effect observed by Miller. After 1930 the MM experiment was never repeated until the 1950s. In other words, after 1930 the experimental issue was considered a closed question and Miller’s interpretation of his observations was discarded by the scientific community. In this rejection of Miller’s results, the last two experiments played a decisive role: the Michelson-Pease-Pearson experiment performed in the USA between 1926 and 1928 and Joos’s, which was performed in Jena between 1929 and 1930.[11]

Thus, Miller’s data remained an unexplained result until 1954, when Robert S. Shankland (Miller’s successor at the *Case Physics Department* in Cleveland) and three colleagues at the *Case Institute of Technology*, found a reasonable solution based on the temperature variations in the optical paths of Miller’s interferometer.[12]

Historiographical descriptions

The *standard* version of the history of this subject, found in the scientific treatises, is enough simple and coherent. It can be summarized in this way: Miller’s results were discarded because other MM experiments, which were performed with more sensitive instruments, did not find the same effect; after these repetitions the majority of the scientific community thought that they were due to other systematic causes or some sources of error.[13] Moreover, the majority of scientific books that mentioned Miller’s results after Shankland’s re-analysis affirmed that this solution was the correct one.[14]

In addition to this *standard* history we can find other implicit as well as explicit historical accounts of this issue. Interesting implicit histories of Miller’s ether-drift experiments were in some important writings of the philosophers of science. In particular, M. Polanyi, Lakatos and Feyerabend concerned themselves with the reaction of the scientific community to Miller’s claims with opposite judgements. Feyerabend and, in particular, Polanyi underlined the irrationality of the rejection of Miller’s results, whereas Lakatos affirmed that “the tenacity of the Einsteinian research programme in the face of alleged contrary evidence was a completely *rational* phenomenon”.[15]

Musgrave, (eds.) *Criticism and the Growth of Knowledge* (Cambridge: Cambridge University Press, 1970): 91-195, p. 163 [emphasis in the original]. The epistemological discussions about this case study of M. Polanyi and Feyerabend are in: M. Polanyi, *The Logic of Liberty: Reflections and Rejoinders* (London: Routledge and Kegan Paul Ltd, 1951); M. Polanyi, *Personal Knowledge, Towards a Post-critical Philosophy* (London:

A different mention of Miller's experiments is in some biographies about Einstein, with a specific, but not deepened, description of Einstein's attitude towards them.[16] In very few textbooks of theoretical physics and optics there were some quotations of Miller's experiments in the paragraphs concerned with the null result of the MM experiment. They reported either the *standard* history or an inaccurate version of the history.[17]

The anti-relativists reacted to the rejection of Miller's results with historical analyses based on the prejudice that the scientific community was dogmatic towards relativity and claimed that Shankland's analysis was incorrect and that his principal aim was to complete a work with the support of Einstein. Thus they stated that the *standard* history is false.[18]

Apart form these implicit histories there are a few historical writings about Miller's experiments. The most acknowledged treatise about the history of Miller's experiments is the book *The Ethereal Ether* by Loyd Swenson, but this writing is often used in the anti-relativistic literature, because it shows some ambiguities and utilizes the 1933 Miller's paper and 1955 Shankland's paper as principal sources without a critical analysis.[19]

Miller's experiments found also a place in the treatises *Understanding Relativity* of S. Goldberg and, in particular, *Einstein's Jury* of J. Crelinsten in the historiographical context of the US reception of relativity during the 1920s.[20] A third interesting account of this subject is in the very thorough analysis of Einstein's attitude towards Miller's experiment made by Klaus Hentschel.[21]

The historiographical studies summarized in this section left us with several questions related to the history of Miller's experiments and of their eventual rejection:

- Why, when and how did the MM experiment end?
- Is it possible to speak of a US scientific community related to this issue? If so, what was the reaction of the US scientific community to Miller's claims? Which role (if any) did sociological features play in this national reaction?
- What was Einstein's attitude towards these experiments?
- Which were the different features of the repetitions of the MM experiment performed in the 1920s?
- Why did Shankland decide to redo the difficult re-analysis of Miller's data? How did Shankland's re-analysis reach a possible solution?
- An interesting question could also be asked in relation with philosophical analyses of this history: Which behaviour could be called rational and which could be called irrational in the history related to Miller's strange results?

I try to answer all these questions in my Ph.D. thesis, but in this communication I will focus the attention on the second point related to the reaction of the US scientific community to Miller's claims thanks to scientific literature and private documents found in several US archives.[22]

US reception of Miller's announcements

The 1920s' scientific literature shows that the US scientific community's reception of Miller's results was very different quantitatively as well as qualitatively from that of the European scientific communities. If we asked why, my historical research and other analyses of the US reception of relativity lead to two principal answers:

- In the US scientific community the opinion was diffused that the theory of special relativity was an inductive generalization of the MM experiment.[23] This opinion was due to the epistemological attitudes of the US scientific community as well as to the fact that the experiment was performed in the USA by the first US Nobel prize winner in the sciences. This implied that the MM experiment was an important national scientific discovery for the US scientific community.
- The second reason was a sociological one. Miller was an eminent member of several US scientific societies, the US scientific community regarded him as a skill experimenter and the most important authority in acoustics. In particular, he was the President of the APS when he announced his positive result in 1925. In other words, Miller had an authoritative voice within the US scientific community in the field concerning with the ether-drift experiments.

There are two opposite descriptions of the reaction of the scientists to Miller's public announcement in the 1925 meetings. On the one hand, it is reported that "nobody doubted relativity" and that all scientists thought that "some unknown source of error […] had upset Miller's work".[24] On the other hand, there are at least three pieces of evidence as to a positive response to Miller's announcement: (1) the AAAS awarded Miller with a thousand dollar prize after his lecture on the ether-drift experiments in December 1925; (2) many scientists began to repeat the MM experiment after his announcement in the USA as well as in Europe; (3) the director of *Science Service*, Edwin E. Slosson, wrote to Einstein that Miller's paper "made a deep impression upon the National Academy of Science when it was read [at the April 1925 meeting]".[25]

Thus, it is necessary to analyse the scientific literature of the period and the private documents in order to understand which features this reaction had. By these documents we learn that there were at least three different theoretical responses in the period 1925-26:

A. A strong anti-relativistic reaction, by L. Silberstein, D. C. Miller, C. L. Poor, H. D. Curtis, A. Reuterdahl and others;[26] according to them, Miller's results completely disproved relativity theories.

B. A strong relativistic one by several European theoreticians (A. Einstein, M. Von Laue, M. Planck, Epstein, A. Eddington, H. Thirring, M. Born, Weber, E. Cohn).[27] According to them, Miller's data had nothing to do with an ether-drift and they were very sceptic about the validity of Miller's results.

C. A weak relativistic one by some US relativistic theoreticians who tried to find some modifications of relativity theories that could explain Miller's observations (Page, Sparrow, Swann, Davis, Carmichael).[28]

---

[23] See, for example, R. A. Millikan, "Albert Einstein on His Seventieth Birthday", *Reviews of Modern Physics,* 21 (1949): 343-45. The historian of science G. Holton underlined that this way of seeing was common within the US scientific community: Holton (note 14).

[24] C. G. Darwin, "Logic and Probability in Physics", *Philosophy of Science*, 6 (1939), 48-64, p. 51. Darwin's attestations were fundamental for the epistemological analyses of M. Polanyi and Lakatos (note 15); in particular, they assumed a radical meaning in M. Polanyi, *The Logic of Liberty* (note 15), p. 12; and in R. W. Clark, *Einstein, the Life and Times* (London/Sydney/Auckland/Toronto: Hodder and Stoughton, 1973), p. 316. Moreover, this description was very similar to that of Popper (see note 13).

[25] E. E. Slosson to A. Einstein, 26 June 1925, *Collected Papers of Albert Einstein* (*CPAE*) 17 259 courtesy *Einstein Paper Project* (*EPP*), *California Institute of Technology* (*Caltech*) in Pasadena.

[26] See Crelinsten (note 20); it is interesting to underline that historical researches shows that all the physicists who used Miller's experiments against relativity had already shown that they did not appreciate Einstein's theories for other epistemological or metaphysical reasons.

[27] These names appeared in Einstein's correspondence on this issue. M. Von Laue and M. Planck were quoted in Einstein to Lorentz, 22 June 1926, *CPAE* 16 608; P. Ehrenfest expressed his scepticism in the letter Ehrenfest to Einstein, 16 October 1925, *CPAE* 10 110; A. Metz in Metz to Einstein, 8 January 1926, in A. Einstein, *Ouvres Choises 4 - Correspondances Français: Letters Choises et presentées par Michel Biezunski* (Paris: Editions du SEUIL-Editions du CNRS, 1989), p. 212; P. Epstein in Epstein to Einstein, 19 September 1925, Caltech, Papers of Paul Sophus Epstein (*PPE*), fol. 3.34; E. Cohn to Einstein, 11 September 1925, *CPAE* 17 263; Weber to Einstein, 23 December 1925, *CPAE* 23 284; the wife of M. Born wrote to Einstein that Born doubted the reliability of Miller's instrument after his visit to Mount Wilson in Hedi Born to Einstein, 11 April 1926, quoted in Albert Einstein – Hedwig and Max Born, *Scienza e vita, lettere 1916-1955* (Torino, Boringhieri, 1973), p. 107.

[28] W. F. G. Swann, "The Relation of the Restricted to the General Theory of Relativity and the Significance of the Michelson-Morley Experiment", *Science*, 62 (1925): 145-49. L. Page, and M. Sparrow, "Relativity and Miller's Repetition of the Michelson-Morley Experiment", *Physical Review*, 28 (1926): 384-91; Carmichael et al. (1927) *A Debate on the Theory of Relativity* (Chicago/London: Open Court, 1927).

In this short list it is evident that the US reaction was different from the European one in two principal facts: first, the reaction (C) was a peculiarity of the US theoreticians that has no similarity in Europe; second, the anti-relativistic reaction (A) was not so strong in Europe. For example Sir Oliver Lodge believed in the reality of the ether but he accepted the null result of the MM experiment and did not regard Miller's result as a real issue for relativity.[29]

In any way, the most common public attitude in the period 1925-26 was to wait for other experiments performed by other scientists, before giving a conclusive opinion. Einstein agreed on the necessity of ulterior MM experiments and appeared to be sure that they would confirm the null result.

Theoretical and experimental issues

Miller was not a theoretician and he needed the help of someone else in order to calculate the earth's cosmic velocity that could be in accord with his data. In 1925 he affirmed that his data were consistent with an absolute earth's velocity of 200km/s, which was proposed by the MWO astronomer Strömberg in order to explain asymmetries in stellar radial velocities, but the ether-drift showed only a *reduced* velocity of 10km/s at the top of Mount Wilson.[30]

After Miller's April 1925 announcement, Silberstein claimed that relativity theories were disproved and Miller's data could be explained with the Stokes-Planck ether, which was a compressible ether dragged by the earth's surface.[31] Silberstein's proposal was a general justification, but Miller was very hesitant about the effective behaviour of the ether that could explain his observations at Mount Wilson:

- In the April 1925 meeting, Miller claimed that the drag changed with altitude;
- On the contrary, in the December 1925 meeting, he affirmed that the ether could be dragged from the opaque and massive shielding (for example the walls of the laboratory room);
- In the same meeting he also proposed a third possibility, that is a modified Lorentz-Fitzgerald contraction with a stationary ether.

In addition to the confusion about these explanations there was also an unexplainable effect periodic in one turn of the interferometer, and Miller's ether-drift interpretation of his data could not explain a variation of the azimuth of 30 degrees since the algebraic sum of the east-west components of the drift during a sidereal day had to be zero.

Apart from these theoretical problems, in the same period in which Miller announced his finding other US experiments were all in favour of general relativity theory. In fact, in the same April 1925 meeting, Gale reported that the Michelson-Gale experiment showed a result in agreement with general relativity theory as well as the stationary ether theory, but it disproved an ether-dragged theory (the only one that could be used to explain Miller's data).[32] The Michelson-Gale experiment played a relevant role in reducing the significance of Miller's experiments for several reasons, in particular, because it was proposed by Silberstein in order to confute relativity and to prove the Stokes-Planck ether theory, and because its result was contemporary to Miller's one.

Moreover, before Miller's claims, other US tests of general relativity theory were all in agreement with Einstein's prediction: in 1922 Campbell confirmed Eddington's conclusion about the light deflection around the sun, in 1923 St. John changed his opinion about the red-shift of solar spectral line and in 1925 Adams confirmed Eddington's relativistic prediction about the stellar red-shift of Syrius B.[33]

At the beginning of 1926 the situation about Miller's experiments was: Miller's results could be used against relativity theories, but there was not an advanced ether theory that could compete with relativity, because (1) an ether that could

explain Miller's data was not in accord with other known facts (in particular, the Michelson-Gale experiment and stellar aberration), and (2) Miller's interpretation needed some *ad hoc* hypotheses about the ether-drag. Furthermore, Miller proposed different *ad hoc* hypotheses in different reports: the relation with altitude in April 1925, and an ether dragged by the walls of the laboratory room or a modified Lorentz-Fitzgerald contraction in December 1925.

Other repetitions and Michelson's role

In spite of these theoretical problems, there was a sort of confusion about Miller's results and some institutions planned a repetition of the MM experiment. All these experiments concluded with the confirmation of the null result.

In the USA the Caltech as well as the MWO decided to re-perform the experiment. The first US repetition of the MM experiment was realized by Roy J. Kennedy of the Caltech in September 1926.[34] Kennedy's instrument was very sensitive. In order to eliminate temperature and pressure effects he enclosed the optical system in a sealed metal case containing helium at atmospheric pressure. This procedure was methodologically opposed to Miller's, who attempted to eliminate all the alterations of the ambient condition, which were able to interfere with the detection of the ether-drift effect. In fact, Miller enclosed the optical path with transparent glasses in order to not interfere with the free ether wind. After one year Kennedy's experiment was repeated by K. K. Illingworth with an improved apparatus. His conclusion was that his observations were in sharp disagreement with Miller's; no shift dependent on orientation was observed.[35]

Despite the excellence of their apparatus, the experiments of Kennedy and Illingworth were not sufficient to end the debate about Miller's ether-drift experiments. Furthermore, their names were not quoted very often in scientific literature, unlike Miller, whose observations appeared in a number of textbooks as the most extensive series of measurements of the MM experiment.[36] The reason for the limited impact of the Caltech experiments is not very clear; in any case, it seems that Michelson's work had a larger influence on the US scientific community's eventual rejection of Miller's results.

We can now focus our attention on Michelson's role in the eventual conclusion of the MM experiments in the USA. The director of the MWO, Walter Adams, asked him to redo the MM experiment in 1926. Adams wrote a letter in which he tried to convince Michelson that the repetition of the MM experiment was still more important than the velocity of light measurements. This letter was written after Kennedy's announcement because Michelson regarded Kennedy's experiment as conclusive.[37] In this letter, other private documents and public announcements it clearly appears that Michelson was not very interested in the repetition of the MM experiment for several reasons, but Adams urged him to continue the task since the scientific world wanted an ether-drift experiment performed by the authoritative Michelson. The expressions used by Adams are indicative of relevance of Michelson's work within the US scientific community. In fact, Adams wrote: "I understand that Kennedy got zero effects […] but what the scientific world wants is your final word on the subject".[38]

Thus Michelson, with the help of Pease and Pearson, made some observations between June 1926 and March 1928. At the beginning of 1929 they published two very short reports, in *Nature* and in the *Journal of the Optical Society of America*. There was no data at all and a very brief description of the apparatus was provided. They were almost identical with a slight, but strange, difference in the conclusion: in the *Nature* paper, published in January 1929, the authors affirmed that "the results gave no displacement as great as one fifteenth of that to be expected on the supposition of an effect due to a motion of the solar system of three hundred kilometres per second", whereas in the *JOSA* paper the amount became "one-fiftieth".[39]

[36] See for example F. A. Jenkins, and H. E. White *Fundamentals of Optics* (2nd ed., York/Toronto/London: McGraw-Hill, 1950), p. 398; F. W. Van Name, *Modern Physics: Developments of the Twentieth Century* (New York: Prentice-Hall, 1952), p. 84; F. K. Richtmyer, *Introduction to Modern Physics* (2nd ed., New York: McGraw-Hill, 1934), p. 715. Sometimes Miller's experiments were quoted as experiments that confirmed the negative result. See H. M. Schwartz, *Introduction to Special Relativity* (New York: McGraw-Hill, 1968), p. 35.

[37] There are several pieces of evidence that show Michelson's public opinion about the reliability of Kennedy's experiments. See, for example, Michelson et al. (1928) "Conference on the Michelson-Morley Experiment: Held at the Mount Wilson Observatory Pasadena California, February 4 and 4, 1927", *The Astrophysical Journal*, 63 (1928): 341-402, p. 393.

[38] Adams to Michelson, 24 November, 1926, [emphasis of Adams], *US Naval Academy* (*USNA*), *Nimitz Library Special Collection and Archives Division*, Albert A. Michelson Papers, fol. 1.

[39] A. A. Michelson, F. G. Pease and F. Pearson, "Repetition of the Michelson-Morley Experiment", *Nature*, 123 (1929): 88, and A. A. Michelson, F. G. Pease and F. Pearson, "Repetition of the Michelson-Morley Experiment", *Journal of Optical Society of America*, 18 (1929): 181-82, p. 182.

Another peculiar detail of these two reports was that Michelson and his co-authors opted not to refer directly to Miller's experiments, but to Strömberg's cosmic motion theory, which Miller had used in order to explain his data. This choice generated some confusion because Miller's data agreed with Strömberg's motion only as a result of fundamental modifications, as for example the hypothesis of an ether drag of 19/20. Thus the Michelson-Pease-Pearson data resulted not to be an explicit disproval of Miller's ether-drift of 10km/s. The fact that the authors did not directly refer to Miller's experiments leads us to a question: Why was Michelson so ambiguous in these publications?

It is possible to find some potential explanations of Michelson's behaviour in private correspondence of some scientists involved in Michelson's experiment. The US scientific community firmly trusted Michelson's last word on the MM experiments, but it does not seem that Michelson was really interested in these experiments for several different reasons. First, he had no doubts about the null result of this kind of experiment.[40] Second, he did not appreciate Miller's methodology and he never regarded his observations as valid, in particular he stated that Miller did not change the experimental conditions enough.[41] Third, he believed that Kennedy's results were sufficient to conclude the question once and for all. Lastly, he considered the new light velocity measurements as more important than a new repetition of the MM experiment. Thus, the US scientific community, thanks to Adams, put pressure on him to repeat these experiments against his personal convictions. The US scientific community's need for the authoritative position of Michelson clashed with Michelson's own behaviour who did not make many efforts in this task. It seems that these are the motivations of Michelson's alleged ambiguity, along with his reluctance in attacking Miller's expertise too directly.

Conclusion

After this short account we can try to reach some conclusions about the reaction of the US scientific community to Miller's results in the 1930s. The need for *the final word*, which we have seen in Adams' letter, means that the US scientific community could not discard the ether-drift found by Miller without an authoritative response. Michelson was the only scientist that could play this role, because he was regarded as the most important expert of this kind of experiments. But, in a paradoxical way, his confirmation of the null result was more uncertain and unclear then Kennedy's or Illingworth's. This situation created some confusion about the rejection of Miller's results, even though there were several other rational reasons for it.

This sociological attitude, linked to the importance of the authoritative word, had the consequence that the importance of Miller's experiments was overemphasized in the US scientific community, in fact Miller, as we have seen, never calculated a cosmic motion that could fit all his data. Thus we can discard some anti-relativistic claims, because sociological or irrational reasons had a role more on the excessive importance of Miller's experiments than on their final rejection.

[40] In 1925 Michelson wrote to Hale that: "the 'Ether drift' experiments finished with decidedly negative results – probably zero displacement but certainly less than one thirtieth of that which Miller found". Undated handwritten note found in *Huntington Library*, Walter S. Adams Papers, box 46, fol. Michelson 1925. Even though this note is undated it appears that it was written soon after Miller's April 1925 announcement. It shows that Michelson had no doubts about the null result of the original Michelson-Morley experiment.

THE APPROACHES TO THE CREATION OF TYPOLOGICAL STRUCTURES FOR THE DERIVATION OF LORENTZ TRANSFORMATION

O. SHCHERBAK, W. SAVCUK
Dnepropetrovsk National University, UKRAINE
elena.scherbak@mail.ru

Abstract

The analysis of the original issues of the approaches to Lorentz transformations derivation witnesses that they had an evolutionary character which was connected with their applications to the different physical systems and mediums possibilities extensions. In this issue, through the analysis of mathematical methods which were applied while deriving the Lorentz transformations, four major directions which dominated in the first part of the 20th century are investigated. We have pointed out four founders of these directions:
- coordinate approach (V. Voight, G. Fitzgerald, J. Larmor, A. Poincaré, H. Lorentz, A. Einstein, I. Kordysch);
- group approach (H. Minkowski, A. Poincaré, V. Varicak);
- tensor approach (Einstein, Ivanickaya);
- matrix approach (H. Minkowski, A. Poincaré).
The main peculiarities are shown of these approaches and their realizations, through examples of European scientists' works.

Classical physics, based on the Newton equations, described the phenomena of causal relations through differential equations. Even the Maxwell equations implicitly implied relativistic conditions and contained the conditions of classical physics abandonment. The way to the complete construction of electrodynamics and the Maxwell equations declassification became possible only after the construction of the special theory of relativity and the consideration of the relativity principle. But it was necessary to review the basic principles of classical physics, space and time.

The periodization of the development of relativistic physics in our history of science was mostly connected with some significant historical stages: the time before the October Revolution and the post October Revolution period. In our view, this approach is not crucial, so while considering the topic, the timing from 1900 to 1924 was selected in order to highlight the first ideas of the special theory of relativity that emerged at the beginning of the twentieth century and had already been taken by the scientific community in the 1920s after the GTR establishment. Also, the intensive development of quantum theory confirmed the fairness of the mass and energy correlation formula, which indirectly confirmed the fairness of ETS. This periodization is also relevant because at the beginning of the 1920s a change of the political system took place in

Ukraine that led to fundamental changes in the structure of science, and became an important factor in the development of scientific research, including physics.

In order to determine STR trends in Ukraine and define its conceptual ideas, we would like to present, in this report, the results of the studies based on comparing the local scientists' works, their approaches to STR and the global trends of the problem analysis.

The equations called the Lorenz equations played an important role in the formation of modern physics. The "birth" of the Lorentz transformations began with a "paradox". It implies the fact that Maxwell's equations which characterize the electromagnetic field are not invariant to Galilee's transformations. Moreover, W. Vogt (Voight) showed in 1887 that the equation of the type φ=0 remains in the transition to new space-time variables by transformations of the type $x'=x-vt$, $y'=y/\gamma$, $z'=z/\gamma$, $t'=t-vx/c^2$. They were practically the future Lorentz transformations up to the scale factor. W. Vogt's work was little known to the scientific community. But J. Fitzgerald and H. Lorenz realized that in order to explain the Michelson-Morley experiments it is necessary to introduce a new postulate (reducing the size of moving bodies). In 1900, ten years after H. Hertz and O. Heaviside gave a beautiful mathematical form to the Maxwell equation, J. Larmor found the transformation in which the equations remained invariant. The method proposed by J. Larmor was reduced to a two-stage scheme: at first it is the Galilean transformation, and then the restoration of the Maxwell equations' invariance through kinematic transformation, which was explained by the author as follows: «The size of moving electrodynamics system declines along the movement direction compared with a system that is at rest with respect to $(1-v^2/c^2)^{-1/2}$». H. Lorentz, regardless J. Larmor, proposed a method of transforming one system framework to another at which the Maxwell equations retain their form. In fact, this scheme was similar to that of J. Larmor's. The transformations, $x'=klx$, $y'=ly$, $z'=lz$, where $k^2 = \frac{c^2}{c^2-\omega^2}$ where ω is the speed of the system as a whole, along the x direction, describe the transition between two different systems that were at rest relatively to aether. Therefore, if there was no electromagnetic field in one system, there was no electromagnetic field in the other. This fact explained through the Lorentz theory the result of the Michelson-Morley experiment.

A. Poincaré improved H. Lorentz's aether-field theory removing the Galilean transformations as a separate stage of transformations and immediately entered the equation as a single transformation. A. Poincaré's theory mathematically corresponds to the STR of A. Einstein, but A. Einstein himself «dared» to give physical meaning to the Lorentz transformations. As H. Lorenz wrote in 1912, «Einstein's merit is that he was the first to demonstrate the principle of relativity as a general strictly and precisely acting law» [refer to 1]. However, despite full understanding of the mathematical side of the issue H. Lorenz could not accept the conclusions that resulted from the kinematic interpretation of STR.

As physical objects and their corresponding geometric images cannot depend on where the system recorded their coordinates, studying approaches to the Lorentz transformations derivations one can introduce the classification based on the principles of physical phenomena mathematical descriptions. Considering the nature of the mathematical transformations of the coordinates of these objects, one can say to which class they belong: vectors or tensors.

Historically, the first was a coordinate method which can be most informatively illustrated through A. Einstein's paper [2]. Considering the proliferation of the light signal in both time and space, the equation type like $\frac{\partial\tau}{\partial x'} + \frac{v}{V^2-v^2}\frac{\partial\tau}{\partial t} = 0$ was analyzed. The distribution of light waves was considered in the terms of the two reference frames (one moved uniformly and rectilinearly; and the other was in the state of rest). Using the light speed invariance postulate, and basing on the equation analysis of light waves propagation in these systems, the Lorentz transformations equations were obtained. Accordingly, in the same work physical values of the obtained equations for moving bodies and clocks were obtained, and a velocity addition theorem was given. The given results were applied to the transformation of Maxwell-Hertz equations in void, the theory of aberration and the Doppler principle, the theory of light pressure, dynamics of accelerated electrons and so forth. As part of this approach, L. Kordysch and A. Hruzintsev made the research in the Ukraine in the early 20th century. It should be noted that their issues were published at the same time (1910-1911). Although the articles were devoted to the same topic, the approaches to the derivation of the Lorentz transformations were *not identical*.

In spite of the fact that Kordysch's issue "Elementary derivation of basic formulas of the theory of relativity"[3] was printed in 1911, it had been reported much earlier (15 February 1910) on the conference in Kiev Polytechnic Institute's scientific and technical society. L. Kordysch did the derivation of the Lorentz transformations in a way that was completely covered by the coordinate method definition. (Under the coordinate method we mean the description of a physical phenomenon which is based on linear transformations of the rectangular coordinate system.) Let us suppose that the light signal was released at the time of coordinate systems I and II with their coordinate origin coincidence. Based on the definition of the relativity principle, both the observer of the reference frame I and the observer of the reference frame II will need to see the second light wave spreading from the centers *A* (for coordinate system I) and *B* (for coordinate system II). System I moves with respect to system II with the speed *v*. The wave propagation sphere equation for observer I is:

$$x^2 + y^2 + z^2 - c^2t^2 = 0 \qquad (1)$$

For observer II the equation is:

$$x'^2 + y'^2 + z'^2 - c^2 t'^2 = 0 \qquad (2)$$

System II clock reading is a function of the coordinates, so *t'* can be represented as:

$$t' = At + Bx + Cy + Dz \qquad (3)$$

where, *x*, *y*, *z* are the clocks coordinates relative to I, and *A*, *B*, *C*, *D* are some constants.

Let us assume that the dependence may be more complicated:

$$t' = At + Bx + Cy + Dz + Kt^2 + Mx^2 + ... + Ltx \qquad (4)$$

Let the time t=0, the coordinates $x=l$, $y=z$=0, the moving clocks reading $t'_1=Bl+Ml^2$. Since after *t* seconds the system will shift to the distance *vt*, the reading of the moving clocks will be as follows:

$$t'_2 = At + B(l + vt) + Kt^2 + Ml^2 + Lt(l + vt) \qquad (5)$$

$$\Delta t = t'_2 - t'_1 = At + Bvt + Kt^2 + M(2vtl + t^2) + Lt(l + vt) \qquad (6)$$

As reading of the clocks cannot depend on their location *l* in the system, the condition *M=L=0* is supposed to be performed.

According to our analysis, L. Kordysch, while deriving the Lorentz transformations, based on the equality of inertial reference frames, and this does not contradict the linear coordinates and time transformation changing one inertial reference frame to another. Under these conditions he determined which coefficients would be zero and which ones were to be identified. After finding zero coefficients L. Kordysch received the following dependencies:

$$x' = A(x - vt)$$
$$y' = My \qquad (7)$$
$$z' = Nz$$

Using the conversion formulas (7) and (3) and considering that (1) must be identical to (2), L. Kordysch determined the coefficients: $A = \dfrac{1}{\sqrt{1 - \dfrac{v^2}{c^2}}}$, $B = \dfrac{v}{c}\sqrt{\dfrac{1}{c^2 - v^2}}$, $M = N = 1$.

This way he obtained the Lorentz transformations:

$$x' = \beta(x - vt) \qquad y' = y$$
$$z' = z \qquad t' = \beta\left(1 - \frac{v}{c^2}x\right)$$

where $\beta = \dfrac{1}{\sqrt{1 - \dfrac{v^2}{c^2}}}$

Let us note that L. Kordysch adhered to the view that A. Einstein's second postulate was redundant, as it was simply a consequence of the first postulate. This way he supported the view of European scientists. He noted in the preface of this work that a similar conclusion was presented by M. Planck in by that time just printed "Lectures on theoretical physics" (no wonder as L. Kordysch was M. Planck's apprentice). V.S. Ihnatovskyy, F. Franck and G. Rothe reached independently the same conclusions about the second postulate as M. Planck and L. Kordysch did. As E. Whittaker remarked: "when the principle of relativity, to which all physical nature is subject to, was recognized, scientists tried to submit it in a form free from any ties with the electromagnetic theory, so that it could be derived from a more or less defined set of credible axioms. [4, p. 72]

Let us also mention that the approach offered by L. Kordysch is easier than A. Einstein's for the derivation of Lorentz transformations, and readily used in modern physics textbooks (Yavorskyy, Dyatlaf Physics course: High School, 1999 - p. 89-90). We can find the indication to the easier derivation (compared to that of A. Einstein's) in the editor's comments on the article translation "On the Electrodynamics of Moving Bodies": "they are derived directly from the easier terms by these formulas ratio $\xi^2+\eta^2+\delta^2-V^2\tau^2=0$ which must lead to the relation $x^2+y^2+z^2-V^2t^2=0$ [5]. L. Kordysch was the first to offer this approach.

Gruzintsev A, well-known for developing and compiling the Hertz electrodynamics of light waves propagation in non-conducting media, was an adherent of the aether theory, developing the perspective of aether as the structure closely connected with the electromagnetic field. Therefore he approached the issues of the theory of relativity from the position of electrodynamics in the article "the Lorentz transformations and the principal of relativity" [6]. His approach is associated, as shown in our analysis, with the coordinate method for the methodological scheme. Unlike L. Kordysch, who ran prior to the Lorentz transformations through the intervals comparison, Gruzintsev A. chose A. Einstein's way and derived the Lorentz transformations considering time in one system against the other as a function of coordinates and time, i.e. $t'=\hat{O}(z,t)$.

The issue begins with the derivation of the Lorentz transformations using the *A* system coordinates and time *x*, *y*, *z*, *t* dependence of the coordinates and time *x'*, *y'*, *z'*, *t'* of the *B* system (which relatively moves with constant velocity) by defining time as a physical factor phenomena observed. Though the approach to this problem in general coincides with that of A. Einstein's, there is a significant difference. The speed of light ω which appears in Gruzintsev A. paper is "speed of light in the medium space is filled with" [6, p.2].

When entering t'_0, t'_1 which is the time of the beam output from *A* system indicated through system *B*; t'_2 is the reflection time from *B* and returning to *A*, Gruzintsev put down the functional dependence of time and broke t'_1, t'_2 after the Taylor method:

$$t'_0=\hat{O}(z,t)$$
$$t'_1=\hat{O}\left(z-u,t+\frac{u}{\omega+v}\right)=\hat{O}(z,t)-\frac{\partial\hat{O}}{\partial z}u+\frac{\partial\hat{O}}{\partial t}\frac{u}{\omega+v}$$
$$t'_2=\hat{O}\left(z,t+\frac{u}{\omega+v}+\frac{u}{\omega-v}\right)=\hat{O}(z,t)+\frac{\partial\hat{O}}{\partial t}\frac{2u\omega}{\omega^2-v^2}$$

The signal in A. Gruzintsev's theory comes from an arbitrary point in space but not from the origin like in A. Einstein's theory. Inserting these values into the formula $t'_1=½(t'_0+t'_2)$, he received the electromagnetic wave equation $\frac{\partial\hat{O}}{\partial u}+\frac{v}{\omega^2-v^2}\frac{\partial\hat{O}}{\partial t}=0$. Further, solving it relating to a Φ function and following A. Einstein's path, A. Gruzintsev found the Lorentz transformations.

Since A. Gruzintsev, as mentioned above, developed the electromagnetic field theory, he was one of the first scientists in Ukraine who applied STR to describe phenomena in the electromagnetic field. The foreword noted that the Lorentz transformations, which were analyzed by A. Einstein, A. Poincaré and H. Minkowski, were considered for the aether only. The aim of A. Gruzintsev's issue was to prove that "H. Lorentz's proposal appears valid for every physical medium which is characterized by the dielectric constant and magnetic permeability coefficient different from unity (for the aether *K*=1, μ=1), moreover, it is valid for mid-absorbing medium (metal)" [6, p.1]. When he was solving this problem he imposed the conditions so that "the speed of light was not the universal constant, i.e. the speed in the aether, for example as A. Einstein supposed, but in general, the speed of light in the examined medium" [6, p.2].

Further, the Lorentz transformations in the form $\frac{\partial U}{\partial t}=k\left(\frac{\partial U}{\partial t'}-v\frac{\partial U}{\partial z'}\right)$; $\frac{\partial U}{\partial z}=k\left(\frac{\partial U}{\partial z'}-\frac{v}{\omega^2}\frac{\partial U}{\partial t'}\right)$; $\frac{\partial U}{\partial x}=\frac{\partial U}{\partial x'}$; $\frac{\partial U}{\partial y}=\frac{\partial U}{\partial y'}$ were applied to the equations of the electromagnetic field in the dielectric as

$$AK\mu\frac{\partial\alpha}{\partial t}=4\pi\left(\frac{\partial g}{\partial z}-\frac{\partial h}{\partial y}\right)$$
$$AK\mu\frac{\partial\beta}{\partial t}=4\pi\left(\frac{\partial h}{\partial x}-\frac{\partial f}{\partial z}\right)$$
$$AK\mu\frac{\partial\gamma}{\partial t}=4\pi\left(\frac{\partial f}{\partial y}-\frac{\partial g}{\partial x}\right)$$
$$\frac{\partial\alpha}{\partial x}+\frac{\partial\beta}{\partial y}+\frac{\partial\gamma}{\partial z}=0$$

where *K* is the dielectric constant, μ is the magnetic permeability, α, β, γ are the components of magnetic force that is calculated per unit of magnetic masses, [6, p.8] *f*, *g*, *h* are the components of the electric displacement. After that

$$\left.\begin{array}{l} AK\mu\dfrac{\partial}{\partial t'}\left(k\alpha+\dfrac{4\pi kv}{AK\mu\omega^2}g\right)=4\pi\left[\dfrac{\partial}{\partial z'}\left(kg+\dfrac{AK\mu kv}{4\pi}\alpha\right)-\dfrac{\partial h}{\partial y'}\right] \\ AK\mu\dfrac{\partial}{\partial t'}\left(k\beta+\dfrac{4\pi kv}{AK\mu\omega^2}f\right)=4\pi\left[\dfrac{\partial h}{\partial z'}-\dfrac{\partial}{\partial z'}\left(kf-\dfrac{AK\mu kv}{4\pi}\beta\right)\right] \end{array}\right\} \text{ was received.}$$

The equation $AK\mu\frac{\partial\gamma}{\partial t}=4\pi\left(\frac{\partial f}{\partial y}-\frac{\partial g}{\partial x}\right)$ from the transformation moved to $AK\mu k\left(\frac{\partial\gamma}{\partial t'}-v\frac{\partial\gamma}{\partial z'}\right)=4\pi\left(\frac{\partial f}{\partial y'}-\frac{\partial g}{\partial x'}\right)$ (*). And the equation $\frac{\partial\alpha}{\partial x}+\frac{\partial\beta}{\partial y}+\frac{\partial\gamma}{\partial z}=0$ moved to $\frac{\partial\alpha}{\partial x'}+\frac{\partial\beta}{\partial y'}+k\left(\frac{\partial\gamma}{\partial z'}-\frac{v}{\omega^2}\frac{\partial\gamma}{\partial t'}\right)=0 \Rightarrow \frac{\partial\gamma}{\partial z'}=\frac{v}{\omega^2}\frac{\partial\gamma}{\partial t'}-\frac{1}{k}\left(\frac{\partial\alpha}{\partial x'}+\frac{\partial\beta}{\partial y'}\right)$, so the scientist put this expression in the equation (*) $AK\mu k\frac{\partial\gamma}{\partial t'}=4\pi\left[\left(\frac{\partial}{\partial y'}\left(kf-\frac{AK\mu kv}{4\pi}\beta\right)-\frac{\partial}{\partial x'}\left(kg+\frac{AK\mu kv}{4\pi}\alpha\right)\right)\right]$ (**), and marked $kf-\frac{AK\mu kv}{4\pi}\beta=Nf'$; $kg+\frac{AK\mu kv}{4\pi}\alpha=Ng'$; $k\alpha+\frac{AK\mu kv}{4\pi}g=N\alpha'$; $k\beta-\frac{AK\mu kv}{4\pi}f=N\beta'$ (***), $h=Nh'$, $\gamma=N\gamma'$ and as N is an arbitrary coefficient, after putting the above marked equations (***) in the equation (**) he obtained:

$$Ak\mu\frac{\partial\alpha'}{\partial t'}=4\pi\left(\frac{\partial g'}{\partial z'}-\frac{\partial h'}{\partial y'}\right)$$

$$Ak\mu\frac{\partial\beta'}{\partial t'}=4\pi\left(\frac{\partial h'}{\partial x'}-\frac{\partial f'}{\partial z'}\right)$$

$$Ak\mu\frac{\partial\gamma'}{\partial t'}=4\pi\left(\frac{\partial f'}{\partial y'}-\frac{\partial g'}{\partial x'}\right)$$

Making the same research for the system of equations which described the electrical component of electromagnetic oscillation, A. Gruzintsev came to the conclusion that the equations system of the electromagnetic field was transformed by the Lorentz transformations in a similar system if the relation $A^2K\mu\omega^2=1$ was valid. If we marked $\omega_0/\omega=n$, we could see that the scientist obtained $K\mu=n^2$, the Maxwell formula, where n "is the index of refraction of our medium". We would like to draw your attention to the fact that A is equal to $1/\omega_0$ in A. Gruzintsev's signs, where ω_0 is "the velocity in the vacuum".

The next step made by the scientist was the consideration of the medium: "there are electrons with charges which move, i.e. the medium has dispersion". Considering the electromagnetic field equations for this case with the contribution dispersion, the scientist received the expression $A^2K\mu\omega^2D_i=1$ where he got "the universal dispersion relation generally accepted at present (…). Thus the Lorentz transformations lead to the important results which are usually derived from the integration of electromagnetic field equations". [6, p.14]. When A. Gruzintsev took into account the conduction currents "in the general sense of the word» for the case of "periodic changes of kinetic medium" and conductivity coefficient C, he received the equity $A^2K\mu\omega^2E=1$. Under the circumstances he derived "Maxwell's formula for conductors (metals) or medium which absorb." [6, p.15]

Actually, A. Gruzintsev, one of the first in the world, proved the invariance of the Maxwell equations for the medium from the Lorentz transformations. This conclusion made by the scientist regardless other researchers was very important in terms of the theory of relativity justification. As he noted "it is clear that the Lorentz transformations for general cases take place only for periodic changes in the electromagnetic field and this is the case for all kinds of optical phenomena and for the most part, if not all, of electrodynamics." [6, p.19]

The Lorenz transformations began their life as those which "allowed" the Maxwell equations to remain invariant. The physical meaning founded there was spread by A. Einstein to the conceptual ideas of space and time. The evolution of the Lorentz transformations' derivation approaches has been finished at this point.

In 1912 N. Umov proved the mathematical meaning of the principle of relativity is the propagation of light wave equation invariance considering the wave process, "without making any preliminary supposition" concerning the law combining x', y', z'. The scientist was the one of the first who in his issue "predicted" the generalized Lorenz equations introduction noting that "whereas x, y, z mean rectangular coordinates, x', y', z' may be curvilinear [7, p. 499]. He found the general transformation. Finding a common transformation for the system $\left.\begin{aligned}\frac{1}{\omega^2}\frac{\partial^2\varphi}{\partial t^2}=\frac{\partial^2\varphi}{\partial x^2}+\frac{\partial^2\varphi}{\partial y^2}+\frac{\partial^2\varphi}{\partial z^2}\\ \frac{1}{\omega^2}\frac{\partial^2\varphi}{\partial t'^2}=\frac{\partial^2\varphi}{\partial x'^2}+\frac{\partial^2\varphi}{\partial y'^2}+\frac{\partial^2\varphi}{\partial z'^2}\end{aligned}\right\}$, which describes the phenomenon characterized by the function $\varphi(x,y,z,t)$ in two isotropic equivalent worlds, he derived the general transformation (for which, as he noted, "introducing the intermediate coordinate" [7, p.498] one could obtain the Lorentz transformations). But M. Umov mentioned that it could simplify the situation by introducing the single coordinate dependence of time. He got the Lorentz transformations as the result of his reasoning.

V. Fock expounded in the issue [8] a strict mathematical proof of the Lorentz transformations' properties. He proved that the requirement of the invariance wave-front equation $\left(\frac{\partial\omega}{\partial x_0}\right)^2-\left\{\left(\frac{\partial\omega}{\partial x_1}\right)^2+\left(\frac{\partial\omega}{\partial x_2}\right)^2+\left(\frac{\partial\omega}{\partial x_3}\right)^2\right\}=0$ (where $\omega(x_0,x_1,x_2,x_3)=0$ the surface equation of wave front), regarding the systems *S* and *S'* did not lead to the Lorentz transformations itself, because it assumed Möbius' transformations. In order to avoid this it is necessary to impose the condition maintaining the straightness and uniformity of movement.

The opportunities for clarification of the Lorentz transformations' derivation using other approaches continued. As we can see, at the beginning the validity of transformations was proved only for the transitions between the two systems moving uniformly and rectilinearly with respect to one another. The process of improving the approaches to the Lorentz transformations derivations (which first were only valid for the transition between two Cartesian systems moving uniformly and rectilinearly with respect to one another) continued.

The formulated four-dimensional concept of space-time gave another approach to the Lorentz transformations' derivation. The key role in this belonged to A. Poincaré, H. Minkowski and W. Varychak [9-12]. Putting away the question of priorities in the special theory of relativity creation, we would like to mention A. Poincaré's contribution. We know that Poincaré's paper which presented the ideas similar to the ideas of Einstein's special relativity came out a few weeks later in a not well-known Italian journal. But before A. Einstein, A. Poincaré, at the congress in Saint-Louis in 1904, put forward the idea that the speed of light could not be exceeded by the other speeds. The scientist discovered the group character of the Lorentz transformations, thus he initiated a new type of symmetry connected with a group of linear space-time transformations and introduced the concept of relativity principle. In an earlier work, A. Poincaré anticipated the special theory of relativity advent paying attention to the need of defining the notion of simultaneity. As U. Frankfurt noted, "In the form in which the Lorentz transformations were recorded before Poincaré, the full covariance equations theory was not achieved. To improve the Lorentz formulas of charge density and speed conversion, Poincaré achieved the total covariance of the equations theory." [1, p. 1927]

In 1910 V. Ignatowsky in [13] issue received the Lorentz transformations avoiding the second postulate of the speed of light constancy but applying the theory of groups. F. Frank and G. Rothe reached the same conclusions in the [14] issue. They noted that "Of all the transformation equations corresponding to the same parametric linear homogeneous groups, there are three types in which the value reduction does not depend on the direction of motion in absolute space. Only one type of them has the effect of the actual length reduction namely the Lorentz transformations (…). In the case of the Lorentz transformations the speed of light in all moving systems in any directions of propagation has the same final value ..." [14, p. 855].

H. Minkowski considered a geometric shape $c^2t^2-x^2-y^2-z^2=1$, where *c* is a positive parameter associated with the group of transformations G_c, where the group of transformations includes a space-time null point shift. Considering the properties of the group in the case of the boundary values of the parameter $c\to\infty$ (Newton approximation), he preferred G_c to G_∞, and further identified the speed of light with this constant *c*.

In 1909 A. Somerfield showed that the composition law for velocities referred to geometry of the imaginary radius sphere. In 1910 V. Varichak on the analogy of the composition law for velocities and intervals addition in Lobachevski geometry plane [10], simplified STR formulas by rewriting them using those for hyperbolic geometry of velocities space: $ct'=-x\cdot shu+ct\cdot chu$, $x'=x\cdot chu-ct\cdot shu$, $y'=y$, $z'=z$. Using 4-dimensional approach proved to be very productive which allowed simplifying considerably the equation and switching to the matrix approach in describing the space-time phenomena. Then the Lorentz transformations can be written as

$$\begin{bmatrix} ct \\ x \\ y \\ z \end{bmatrix} = \begin{bmatrix} \gamma & -\frac{v}{c}\gamma & 0 & 0 \\ -\frac{v}{c}\gamma & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} ct' \\ x' \\ y' \\ z' \end{bmatrix}$$

initiating a matrix approach to the Lorentz transformations derivation.

The analysis of the approaches to the Lorentz transformations' derivation suggests that they were of evolutionary type which was associated with the potential of their applications for various physical systems and mediums. This analysis of different issues enabled us to make a classification of the process. Thus we can distinguish three main trends which were dominant when establishing the Lorentz transformations in the period from 1900 to 1924 as follows:

- A coordinate approach (V. Vogt, J. Fitzgerald, J. Larmor, A. Poincaré, H. Lorentz, A. Einstein);
- A group approach (V. Ignatowsky, H. Minkowski, A. W. Poincaré Varichak);
- A matrix approach (A. Einstein).

The coordinate approach being historically the first was generalized through the introduction of 4-dimensional values which enabled to extend the methods of tensor calculation using in the general theory of relativity to the special theory of relativity. Therefore we can see the process of gradual transition from considering the possibilities of the Lorentz transformations for vacuum to spreading them on the processes in mediums which have the properties different from those of empty space. The further attempts to apply these transformations (with certain restrictions) to speed up –the systems with the appropriate search criteria of proximity were undertaken. It is evident that the methods used for the derivation supplementing each other have "inherited" properties. From the perspective of the STR conceptual ideas, each of the above stages has given a new confirmation of the STR principles' validity and testified the STR new opportunities. The Lorentz transformations have become an everyday tool in studying physical systems to which the special theory of relativity can be applied.

A 'SCIENCE OF EXPORTATION'? INTERNATIONAL SCHOLARSHIP IN THE PROFESSIONALIZATION OF PREHISTORY IN SPAIN (1902-1922)

José María LANZAROTE GUIRAL
PhD Candidate, Department of History, European University Institute (EUI), Florence, ITALY
jose.lanzarote@eui.eu

Abstract

The evolution of prehistory as a scientific discipline in Spain is marked by the contribution of German and French scholars in the first decades of the 20th century. Their role in the study of the Stone Age, and particularly of prehistoric cave art, was paramount; however they were mostly perceived as 'intruders' by the leading Spanish archaeologists. The latter defined prehistory as a patriotic endeavour and felt threatened by the 'foreign' researchers, whom they accused of stealing Spanish past, both materially and symbolically. In this paper, I intend to explore in which ways the rising Spanish prehistorian community defined itself and established its control on the discipline by constructing the 'foreign archaeologist' as antagonist. In doing so, I aim at throwing some light on the origins of this perception, and its lingering influence on the historiography of Spanish archaeology.

Introduction

Recent historiography has highlighted to what extent the process of construction of scientific disciplines has been informed by opposing narratives on the international dimension of science on the one hand and the role of scholars in the nation-state building process on the other. The consolidation of prehistoric archaeology in Spain in the first decades of the 20th century provides an excellent example of the kind of tensions created by those apparently divergent forces. Several European scholars, French and German in particular, contributed largely to the field of Stone Age, and notably to the study of prehistoric cave art. Nevertheless, or perhaps as a result of their prominent role, they were perceived as 'intruders' by Spanish scholars, and particularly by those who were leading the institutionalisation of prehistory in those years.

In what follows, I explore to what extent the presence of those scholars was utilized by the Spanish scholars to demand the establishment of institutions for the practice of prehistory and the protection of archaeological sites and artefacts, stressing their significance as elements of national heritage. In so doing, this paper analyses a historiographical construct, the alleged 'imperialist archaeology' done by those scholars in Spain, in the light of the process of professionalization, as well the instrumental use of nationalist narratives by scientists for the purpose of promoting social and official recognition for their work.

International scholarship: the recognition of prehistoric cave art

1902 marks a turning point in the development of prehistoric studies in Europe. On that date, one of the consolidated voices in the field, Émile Cartailhac (1845–1922) recognised the authenticity of the figurative representations of the cave of Altamira (Santander, Spain). This event inaugurated a new research field, the study of *prehistoric art*, but its significance is enhanced by the fact that Cartailhac was precisely one of the scholars that had denied the authenticity of those representations when the cave was first discovered in 1879. This rejection, supported by the largest sector of the international (and Spanish) scientific community, can be explained by a combination of scientific, philosophical and social factors, in which the fact that the discoverer of the cave, Marcelino Sanz de Sautuola (1831–1888), came from the periphery of prehistoric field, also played a role (Moro and González 2005).

Furthermore, the defence of the paintings was championed by the Spanish geologist Juan de Vilanova (1821–1893); in line with his Catholic beliefs and creationist standpoint, he considered those representations as the first examples of art produced by men, and therefore the proof that humanity was created by God with full intellectual and spiritual capacities. This idea was contested by some leading French prehistorians, under the influence of Gabriel de Mortillet (1821–1898). According to the latter, prehistoric humans, as modern 'primitive peoples' were incapable of high art, which confirmed his strict evolutionist position. In the hands of de Mortillet and those who agreed with him in matters of science and politics, prehistory became a weapon of social combat, as it was brandished in an attempt to reduce the influence of religious ideas in society and advance the cause of materialist philosophy (Hammond 1980; Richard 2008).

The change in the opinion expressed by Cartailhac after the turn of the century is grounded in the redefinition of prehistory's social and scientific credentials, and the shift in its general epistemological paradigm. On the one hand, new approaches in the fields of anthropology and history of religion led to a reappraisal of the intellectual and symbolic capacities of primitive (and prehistoric) populations. On the other hand, the uni–linear and teleological evolutionist paradigm that had dominated the field of prehistory in the 19th century was substituted by the cultural-history approach, which allowed assessing the creative forces of particular human groups and therefore the regional variations in archaeological record (Kaeser 2006). Finally, in the last decades of the 19th century, prehistory was gradually defused from its revolutionary potential; in trying to avoid what they considered partisan uses of knowledge, a new generation of scholars, amongst them some Catholic priests, strove to transform prehistory into a 'neutral' scientific field (Defrance-Jublot 2005).

As a result, after 1902, prehistoric cave art became one of the most promising fields within the prehistoric discipline, for it allowed the exploration of the mental, social and spiritual skills of the prehistoric populations. Cartailhac and the young Henri Breuil (1877–1961) channelled the interest in natural sciences of Prince Albert I of Monaco (1848–1922), who in 1910 created the *Institute de Paléontologie Humaine* (Institute of Human Palaeontology; IPH) in Paris. The new research centre was linked to the *Muséum Nationale d'Histoire Naturelle* (National Museum of Natural History; MNHN), from whence came its director, Marcelin Boule (1861–1942). The IPH enrolled as professors two rising scholars in the field of prehistory, the French Henri Breuil and the German Hugo Obermaier (1877–1946), both trained naturalists, and both Catholic priests.

The new institution aimed at studying the origins of humanity and more particularly prehistoric cave art, and from the very beginning both professors set out to explore the Spanish territory. Whilst Breuil travelled all over the Iberian Peninsula in search of new art stations (Ripoll 1994), Obermaier's activities concentrated on the excavation of El Castillo cave (Santander, Spain), considered as one of the best Palaeolithic sites of Europe, due to its very complete stratigraphic sequence. For this reason, this site became, in economic and scientific terms, the IPH's largest project in its first years, and it attracted a large number of international scholars, who visited the site or collaborated on the digging seasons. Moreover, the work led by Obermaier in El Castillo contributed to the methodological definition of stratigraphic excavation as the prehistorians' method *par excellence,* and the measure of its professionalism (Lanzarote 2011).

Even if the IPH reputed itself as an international institution, it was also deeply rooted in French scientific structures. Indeed its creation implied a decisive move towards the institutionalisation of prehistory and its professionalization, done by means of centralisation in Parisian institutions. In this sense, the IPH opposed the large community of French amateur archaeologists, scattered in the whole country and organised since 1904 in the *Société Préhistorique Française* (French Prehistoric Society; SPF). The excavation activities of a German-speaking Swiss scholar, Otto Hauser (1874–1932) in the prehistoric sites of the Dordogne (France), and the selling of human fossils and prehistoric artefacts, including artworks, to German museums, confirmed the division between those two ways of conceiving prehistoric research. Alarmed by what they considered a looting of the 'underground national archives', French 'official' scholars (Breuil, Boule, Cartailhac) asked their government for a law on excavations which would curtail the 'freedom of excavation' that the amateurs of the SPF proclaimed. Even if the law failed, the claims of those 'official' scholars to control the field were satisfied, at least to some extent, with the creation of the IPH (Hurel 2007).

Colonial sensibilities: counteracting 'foreign science' in Spain

Since their first missions in Spain, the professors of the IPH encountered a country immersed in an intense process of renovation of its scientific and cultural structures, influenced by the consequences of the 1898 colonial crisis. After the military defeat in the Spanish-American War and the subsequent loss of the colonies, Spanish intellectuals had insistently demanded an official effort to redraft scientific policy, oriented towards the regeneration of the country. In this wave of renovation the idea of 'Europeanising' Spain became central, implying the emulation of scientific achievements of the other European nations, but also their colonial potential. This policy led to the reform of the university system and to the creation of new research institutions, such as the *Junta para la Ampliación de Estudios* (Board for the Extension of Studies; JAE) in 1907, which promoted academic exchange by awarding scholarships to study abroad to both students and professors.

Similar goals informed the establishment of the first institution devoted to prehistoric research in Spain, the *Comisión de Investigaciones Prehistóricas y Paleontológicas* (Commission of Prehistoric and Paleontological Research; CIPP). It was created in Madrid in 1912 under the initiative of Eduardo Hernández-Pacheco (1872–1965), chair of geology at the University of Madrid, who had just benefited from a JAE scholarship to visit the MNHN in Paris, at the precise moment in which the IPH started its activities. Upon his return, he proposed to the JAE the creation of an institution within the *Museo Nacional de Ciencias Naturales* (National Museum of Natural Sciences; MNCN), devoted to the geological and prehistoric research in caves and sites. The CIPP mirrored the Parisian *Institut* in its organisation and its research objectives concerned precisely what had attracted the IPH researchers to Spain: the study of archaeological sites and cave art from the Quaternary (Rasilla 2004).

A 'grand amateur' of archaeology, Enrique de Aguilera y Gamboa, marquis de Cerralbo (1845–1922) was chosen as the president of the new institution. Cerralbo was also a political figure, being the leader of the Traditionalist party. In fact, the marquis was welcomed by the JAE, which was accused of being ideologically dominated by progressive politicians, as his participation evinced that the JAE's scientific and patriotic goals went beyond concrete political choices. Finally, Cerralbo attracted to the new institution his protégé, Juan Cabré (1882–1947), a trained artist and archaeologist, who had collaborated with Breuil in the study of the Peninsula's cave art since 1909.

Moreover, Cerralbo using his position as Senator, had contributed largely to the drafting of the *Ley de Excavaciones Arqueológicas* (Law on Archaeological Excavations), passed in 1911. This legal text defined a protectionist framework for the practice of archaeology, and limited the right of non-Spanish citizens to become owners of the discoveries or to export them. In this manner, the law was a crucial step in the definition of prehistoric and paleontological remains as Spanish 'national heritage'. In order to regulate archaeological practice, the law created the *Junta Central de Excavaciones Arqueológicas* (Central Board of Archaeological Excavations), the administrative body entitled to award permits of excavation and to allocate funds (Rasilla and Santamaría 2006). Designated vice-president of this *Junta*, Cerralbo established himself as the guardian of Spanish archaeology and agent of institutionalisation, to which he contributed using his political power and his aristocratic networks.

The passing of the Law on excavations in 1911 and the creation of the CIPP in 1912 are the expression of a desire to regulate archaeological activity and to create scientific structures for its development. Furthermore, those men (Cerralbo, Hernández-Paheco) justified their existence as a defensive effort against 'foreign science'. In this way, Spanish prehistorians used the rhetoric of nationalism to legitimate their discipline in the eyes of society and to consolidate their academic position vis-à-vis the archaeologists that came from abroad. This strategy paid off in a context of hypersensitivity towards what some called 'scientific imperialism', in the aftermath of the colonial crisis, as it had also worked in the French case with the Hauser affaire, in the context of rising anti-Germanic feelings. Singling out 'foreigners' as the antagonist allowed the creation of a group identity, surpassing the social or ideological differences between those who constituted the emerging prehistorian community in Spain, whether noblemen or commoners, official scholars or amateurs, conservative or liberal[1].

For this reason, the activities of the IPH were perceived by Spanish scholars with a mix of admiration (for its methodology and economic means) and mistrust (for their leading role at an international level). In the beginning the relationship between IPH and CIPP was cordial, and there were some attempts to establish formal links between them, but the initiative did not lead to concrete results. Lacking collaborative initiatives, the confrontation finally came about as a dispute between Breuil and Cabré. In August 1913, after a mission in Andalusia, Breuil was informed that Cabré had bribed one of his prospectors, so that he would be informed before the French abbot of the discovery of any new decorated cave (Díaz-Andreu 2000). Breuil's rage was accentuated when he found out that Cabré was preparing a book for the CIPP, *El Arte Rupestre en España* (Cabré, 1915) on a topic that Breuil considered his own scientific preserve (Breuil, 1916). The scientific pride of being the first publisher of new archaeological discoveries, a matter that affected personal ambitions and scientific agendas alike, poisoned the relations between those scholars.

---

[1] These issues are considered in detail in my PhD thesis: *Prehistoria Patria. The construction of prehistoric archaeology in Spain between nationalism and Europeanisation (1900-1936)*, prepared under the supervision of Prof. Antonella Romano, at the European University Institute in Florence.

National identities: Spain as the 'world museum of prehistoric art'

The breach between the institutions deepened in the context of the First World War (1914–1918). Due to the hostilities, archaeological activities by most international scholars, and particularly those of the IPH, ceased or were severely reduced: Breuil was drafted into the French army, and had to combine his work as prehistorian with other activities such as propaganda activities in Spain in favour of the Allies. In turn, Obermaier, a German citizen working in a French institution, lost his position. When the war broke out in summer 1914, he was digging in El Castillo; invited to join the CIPP by Hernández-Pacheco, from then onwards his career developed within Spanish research structures. The War provided neutral Spain with a chance to catch up with Europe in scientific terms; as a result, Spanish prehistorians could affirm their leadership in the discipline, while fostering the definitive shaping of prehistory as a patriotic discipline.

Speaking in front of the *Asociación Española para el Progreso de las Ciencias* (Spanish Association for the Advancement of Sciences) in 1915, Hernández-Pacheco exposed the results of the last years' effort to investigate 'Spanish prehistory and palaeontology'. In his intervention, Hernández-Pacheco established a narrative in which the shortcomings of the 19th century were contrasted against the 're-birth of national science' in the 20th, and claimed a protagonist role for Spain in the field of prehistory on account of the fact that it 'constitutes the world's museum of prehistoric art'. He did not miss the opportunity to remind that the artefacts discovered in the excavations led by the IPH had been taken to Paris, and accused its researchers of conquering 'the Peninsula' for the benefit of French Science by the physical and intellectual appropriation of its national past. He concluded on a somehow positive note, affirming that the presence of 'foreign researchers' had triggered a reaction and that 'the archive of the primitive civilisations, which fortunately for Spanish science, belongs to our homeland, and which, as Spaniards and cultivated people, we ought to preserve and study'[2].

Those ideas were staged at the *Exposición de arte prehistórico español* (Exhibition of Spanish Prehistoric Art) organised in 1921 by the CIPP, along with the aristocratic members of the *Sociedad Española de Amigos del Arte* (Spanish Society of Friends of Art). Organised in Madrid and inaugurated by King Alphonse XIII, the exhibition featured sketches of cave art which were loaned by both institutions, even if the role of the IPH was barely acknowledged. In line with the narrative developed by Hernández-Pacheco, the Exhibition served as a showcase of the work done by Spanish prehistorians, and it presented cave art as the first chapter of the Spanish art tradition, placing the Peninsula at the cultural origins of Western civilisation. Moreover, the exhibition paid tribute to the Spanish 'pioneers' that contributed to the discovery of prehistoric art in the 19th century, Sanz de Sautuola and Vilanova (Hernández-Pacheco 1921). Finally, the display was inspired by a long running history of national unity, and avoided dealing with sensitive issues such as the ongoing scientific debate on the ethnic composition of the Peninsula in prehistoric times, which informed two opposing interpretations on the chronology of the so-called Levantine cave art.

The collaboration of those two institutions at the Exhibition was possible due to the mediation of Obermaier. As a member of the CIPP, he had researched intensively on the geology and prehistory of the Iberian Peninsula during the years of the War. In his book *El Hombre Fósil* (1916), he drew on his previous knowledge and experience in Central Europe and France, to insert the prehistory of Spain into that of the Continent. Even if his relations with Hernández-Pacheco deteriorated to the point that he quit the CIPP, by the end of the First World War, Obermaier had developed close ties with aristocratic patrons and members of the Spanish intelligentsia, particularly those who admired the achievements of German science. Finally, in 1922 he became the first chair of prehistory in Spain at the University of Madrid.

His designation was not achieved without resistance, notably by Hernández-Pacheco, who impeded, from his chair in the Faculty of Sciences, the creation of a new position in this faculty. Finally, Obermaier's chair was established in the Faculty of Humanities, under the name *Historia Primitiva del Hombre* (Primitive history of man), confirming the disciplinary shift of prehistory from natural sciences to humanities. Commenting on his recent appointment, Obermaier wrote to Breuil that the JAE had organised a counter-course and accused the anthropologist Manuel Antón (1849–1929) of affirming: 'foreign prehistorians have built in Spain a science of exportation rather than imported by foreigners'[3]. Ironically, it was him, a 'foreign researcher' who had indeed smuggled archaeological artefacts out of the country[4], who became the first university

[2] "(…) es el archivo de las primitivas civilizaciones, el cual, para suerte de la Ciencia española, poseemos en nuestra Patria y que, como españoles y pueblo culto, estamos en deber de conservar y estudiar". Hernández-Pacheco 1921: 149.

[3] 'los estudiosos prehistóricos han construido en España más una ciencia de exportación que importada por extranjeros', Letter. H. Obermaier to H. Breuil. Madrid. 30 January 1921. Paris, Muséum Nationale d'Histoire Naturelle, Archive Centrale. Fonds Breuil (Br. 38).

[4] In 1912 and 1913 Obermaier sold a collection of artefacts from El Castillo to the American Museum of Natural History in New York. Obermaier acted in this way not just by hiding from the Spanish authorities, who had just implemented new heritage legislation, but also from the Parisian IPH, which asked for exclusivity of research results. The secrecy of those transactions meant that those materials have been kept in storage, unknown by most specialists until recently. See: White 2006.

professor of prehistory in the country. Obermaier acquired Spanish citizenship in 1926, and became the authority on Peninsula's Stone Age at home and abroad until 1936, when the Spanish Civil War again forced him into exile.

Conclusions

The process of professionalization of prehistory in Europe in the first decades of the 20th century resulted from a complex interplay of scientific, social and economic interests, and was inspired by both the internationalism of the academic world and the imperatives of the nation-state building process. For this reason, the alleged 'scientific colonialism' performed by European scholars in Spain seems like a narrative construct of those Spanish prehistorians who strove to consolidate their field by means of legal regulations, institutions and the conversion of archaeological artefacts into 'national heritage' items. Furthermore, those scholars transformed prehistoric cave art into a mighty element for national definition; by so doing, they contributed to a historiography that praised painting tradition as one of Spain's most relevant contributions to Western civilisation, which compensated for what was perceived of as a less decisive contribution in scientific or philosophical terms.

Going beyond the historiography of the alleged Spanish scientific backwardness, the presence of those international scholars can be better grasped as a consequence of the intensification of the country's opening to international influences, the much desired 'Europeanization' of national science. In this context, 'foreign scholars' were perceived as both, eminent scholars to emulate (and to attract as in the case of Obermaier), and competitors to counteract (as for Breuil). The tensions provoked by their presence can be understood as resulting from the strategy of a self-proclaimed national community of prehistorians to establish their control on the discipline. As opposed to the French case, where amateur archaeologists managed to wrestle official ones and hampered the implementation of a law on excavations, the professionalization of archaeology in Spain was driven by official initiative, in which scholars from different social backgrounds collaborated in the name of patriotic regeneration.

WAYS OF DOING CHEMICAL PRODUCTION AT CUF, "COMPANHIA UNIÃO FABRIL" (1909-1972)

Isabel CRUZ
Work Group for the Archives CUF/QUIMIGAL, and
CICTSUL – Centro Interdisciplinar de Ciência, Tecnologia e Sociedade, Universidade de Lisboa, PORTUGAL
isabelnevescruz@netcabo.pt

Abstract

When, in 1906, the Portuguese chemical enterprise Companhia União Fabril *decided to establish its Barreiro works for a European-sized competitive production of phosphate fertilizers, the use of Portuguese pyrites was immediately selected as the S-source for the required sulphuric acid. Another important feature marks the chemical production at Barreiro, which is that from 1909 to 1950 all the sulphuric acid produced was "chamber acid", obtained by the classical lead chamber process.*
With the approach of the end of World War II, there was a need to equate urgent technological reforms for the development of production of acid chemicals (sulphuric, hydrochloric, phosphoric), metals (cooper, lead, gold and silver) and fertilizers (phosphate and nitrogenous). Consequently, by the beginning of the 1950s several important facts happened in CUF, but we stress two among others: the adoption of the contact technology and the implementation of organizational and structural reforms.
Progressing from the former industrial model where, with a simple structure, hierarchically made a centralized command, CUF introduced a dynamic where the technical performance of its employees was not desirable, but also inevitable. In the industrial frame, several Study Centres were introduced, where engineers carried out the specialized technical work to production activities, and a Documentation Centre was also created.
The work which is being proposed aims at understanding the process of CUF's technology adoption between the beginning of sulphuric acid production (1909) and the erection of the first contact plant with fluidization technology (1972), not only in terms of the technologic consumption concept, always present, but also in terms of development of its own technological capacities (Barreiro, chemical production) related with the structures and dynamics established in the meantime.

Introduction

The history of CUF, *Companhia União Fabril*, begins in the second half of the 19th century when, in 1865, was set up the corporation which was responsible for operating the manufacturing plants originally owned by an important businessman in Lisbon trading centre, the Viscount of Junqueira. The chemical production at CUF has its origin there as well. The manufacturing plants concerned produced vegetable oils, soaps and candles (fig.1). It is assumed that the essentially solid residual cake, unintentionally obtained from raw-material pressing, was given a commercial destination already at that time. A few years later, it was apparent that such utilization was made as the material was advertised as organic fertilizers and feed for livestock.

Fig. 1: General scheme of candles, oils and soap integrated productions.
19th century CUF factories.

The currently existing knowledge of the manufacturing procedures and the technical policy used in the initial period of CUF, that is to say, from 1865 until the time when primary inorganic chemistry-based production started (Barreiro, 1909), is still limited. Nevertheless, it is possible to say that it was on the productive pattern beginning at CUF with the 20th century that the bases were laid which enabled it to follow a technological development consistent with the factor of modernity.

Thus, the following text explores those facts linked with the history of the great chemical-industrial manufacturer that CUF became, which are more directly related with that progressive evolution, where the expansion and diversification of the manufactured products were, among several others, determinant factors for the corporate overall growth. Some aspects will be brought into focus, namely those connected with the corporate industrial policy, the structural and organizational reforms performed, the production and dissemination of technical knowledge, the connection with schools, etc.

The chemical-industrial CUF in the first half of the 20th century

Ever since the great turning point, which consisted on building up the manufacturing structures at Barreiro, with which CUF started the primary inorganic chemistry-based production, that a major technology adoption and adjustment style was also marked at this corporation. It is in this initial period of the 20th century, of establishing manufacturing units for the production of acids (sulphuric and hydrochloric acids), metals (copper) and chemicals (sodium sulphate, copper sulphate) that the direct intervention of the "foreign entity" in CUF technology adoption process is expressed in an unambiguous manner. And although he wasn't the only non national technical expert who participated in the construction of Barreiro cluster, it is a fact that the greatest responsibility for its implementation is assigned to the French advisor A. L. Stinville (Auguste Lucien Stinville).[1]

In addition to Stinville, in the primary inorganic chemistry sector, there were further foreign technical consulting services, also provided by persons of recognized proficiency in the corporate working area under development. People who diversified their functions thanks to the wide range of their know-how and of their personal experience in contact with companies and institutions, and who brought to Barreiro site the inflow of technical and scientific knowledge from abroad,

[1] For detailed information about Stinville see SILVA, José Miguel; YOLLANT (2008) – Introducing A. L. Stinville (1868-1949). *In* José Ramón Bertomeu-Sánchez, Duncan Thorburn Burns, Brigitte Van Tiggelen (eds.) – *Proceedings of the 6th International Conference on the History of Chemistry "Neighbours and territories: the evolving identity of Chemistry"*. Louvain-la-neuve, Mémosciences asbl.

thereby being more or less successful. By the end of the decade of the forties - early years of the fifties of the 20th century, a process of profound reorganization of the corporation was in progress. CUF began then to enlarge its technical staff by engaging the personnel necessary for the structures that were in progress and which indicated not only an increasing complexity in the organization, but also a greater critical performance capacity on the technological system.

Fig. 2: Auguste Lucien Stinville. Portrait in "50 Anos da CUF no Barreiro", 1958.

The first technical staff people hired in this 1st stage of the enlargement, essentially carried out for Barreiro manufacturing plants, in the years between the end of the Second World War and the beginning of the fifties, witnessed an industrial dynamics at CUF based on the control made by foremen responsible for the progress of important sectors of the industrial complex, sometimes with some technical qualifications, but who essentially had a consistent practical and empirical knowledge of same.

Besides this new handful of men, mostly engineers assigned to be service heads in Barreiro industrial complex, another and still more reduced senior group, ranking above them in length of service at the corporation, carried out the superior, technical, commercial and industrial management of same as from the headquarters in Lisbon.

Among this group, the engineers Eduardo Madaíl and João da Rocha e Melo enabled for several years, through the Foreign Section and in the so-called 4th Division (Manufacturing Services), one of the two different and historically recognizable ways of accomplishing the technological development at CUF: namely that one, already traditional in the corporation, that was centred on the pattern of the foreign advisor, the intermediary who ensured the dialogue between the two worlds, the world of CUF and that of the available technological knowledge of foreign origin.

Fig. 3: Eduardo Madaíl. Portrait in "50 Anos da CUF no Barreiro", 1958.

Fig. 4: João da Rocha e Melo. Portrait in "50 Anos da CUF no Barreiro", 1958.

This system that articulated the different parties involved in this way worked whenever it was necessary to assess solutions for new problems that interrupted the everyday work of the plants, usually those arising from expansionary industrial policies, such as the increase in production capacity, the new plants and even issues linked with equipment change and operation. Gradually, however, as technological development became more and more urgent, difficulties associated with the adoption of technology, as those related with customs procedures, were made worse in the war context. Moreover, other important problems came about, such as the sudden death of the English advisor Percy Parrish, the disturbance caused in the dialogue with foreign companies resulting thereof and the problems caused by his "transfer of powers". Delays in equipment shipment and in fulfilling purchase orders and even failure to observe established deadlines, as well as troubles in sending information concerning the ongoing projects, among other facts, induced a great desire in the technical staff of CUF - Barreiro in the forties-fifties to attenuate the encumbrance of this systemic dependence.

It has already been explained in another document[2], through the presentation of a "case study", how the technical "staff" of CUF at Barreiro initially dealt with the countless difficulties that hindered the setting up of a mechanical furnace for sodium sulphate, the production of which urged to be increased at CUF in order to respond to the new consumer market requirements, due to the recent expansion of the country's paper pulp industry. That study upheld the importance of the meanwhile created structure at Barreiro industrial complex, of production and maintenance technical services, with their intermediate management positions held by a new generation of licentiates, whose academic degree was given by the *Instituto Superior Técnico* (Higher Technology Institute), the *Faculdade de Engenharia do Porto* (Oporto Engineering Faculty) or by the *Instituto Industrial de Lisboa* (Lisbon Industrial Institute). From this new organization, dated February 17, 1950, six groups arose of related manufacturing plants, called "Zones" (Acids Zone, Fertilizers Zone, Copper Zone, North Zone, Metalworking Zone and Textile Zone). And because each one of these "clusters" of plants, associated with each other by an industrial logic of their own, brought necessarily together the specific problems of that mesh which made them up, it soon started to be defined, within those Zones, Study Centres for the corresponding areas or subjects of study, where those who provided technical service to that production sector were in motion. This cooperation would have supported the initiatives of gradual autonomy of the personnel in these services in relation to external action on technical problems which they could not only identify, but also criticize, evaluate and point out solutions to solve them.

Production, development and investigation at CUF – 2nd half of the 20th century

To this very same subject referred the Battelle Memorial Institute, in its report[3] drawn up in the beginning of 1955, by stressing the importance of developing technical staff and technical services within CUF. The documentary sources that have been consulted show that the contacts with the Battelle Memorial Institute go back at least to the year 1949, the time when CUF would have ordered an opinion from this company concerning the implementation of a technical progress programme.

The new section recommended in this first opinion, and the true prime mover of the technical development to be created at the corporation, is later on (1955) referred to in other Battelle documents as the "research section of CUF", an entity whose initial concern should be to ensure technical services to the production zones. In this incipient stage of introducing a research programme at CUF, the dissociation between routine studies and profound studies did therefore not exist. However, as these production problems were gradually solved and with the adequate personnel training, the demarcation between routine and innovation was expected to occur, as it was necessary for a more advanced stage in the programme development.

The "central group of technologists" would thus start from the solution of production problems like, for example, corrosion, presence of blowholes in big castings, low performances or bad quality of fertilizers and the frequent fibre rupture in textile machines. The services provided by the group would be technical production and control services and they would include industrial engineering and cost control, engineering work in industrial operations (performance studies, troubleshooting, etc.) and accessory work with the purpose of helping the heads of production sectors and to increase productivity. Besides, an enlargement of the already initiated work should be made concerning the establishment of standards for the selection, purchase and preventive maintenance of the equipment (equipment and materials standardization). In its ultimate stage, the duties of this "Production Support Service Sector" would be reduced to an intermittent verification of the work carried out previously and to the work on new types of materials and equipment.

These were some of the orientations given by the Battelle Institute as concerns the development of what will be hereinafter called "CUF research project".

From 1949 to 1955, however, CUF had not given up the intention to proceed with the "research project". As a matter of fact, in 1953, the "Studies and Projects Section" is formalized at CUF. The subject matters comprised in its sphere of

[2] CRUZ, Isabel; ALVES, Maria do Carmo (2010) – An approach to the ways of adopting and adjusting technologies in Portugal, by taking as an example CUF plants at Barreiro. *In* Miguel Figueira de Faria; José Amado Mendes (coordinator) – *Proceedings of the International Conference "Industrialization in Portugal in the 20th century – the case of Barreiro".* Lisbon, EDIUAL, pp. 251 – 275.

[3] The following references made with respect to the Battelle Institute reports were withdrawn from: Luís Alves. *Memorandum* dated March 9, 1955 of the Studies and Projects (CUF-Barreiro) to the Technical Management (CUF- Lisbon). [Evaluation of the Battelle Memorial Institute report concerning the evolution highly recommended for the Studies and Projects Section]. Proc. 215, Studies and Projects. Former DQIM (Inorganic Chemicals and Metals Division) Documentation, CUF. CUF/QUIMIGAL Archives.

action –technology; industrial accounting; evaluation and construction; materials and equipment standardization; production control– and the fact of being followed up by the Documentation Service and the Research Laboratory (the latter without a well defined individuality) placed it half-way between the "Production Support Service Sector" and the 1st stage of the "Technical Progress and Service Sector", both designed by the previously cited Battelle Institute report of 1955. The "Studies and Projects" were a research embryo created at Barreiro, in 1952, by the engineers António Gouveia Portela and Luís Alves.[4]

Fig. 5: António Gouveia Portela.
"Indústria Portuguesa", Abril, 1965.

Fig. 6: Luís Alves. Portrait in
"50 Anos da CUF no Barreiro", 1958.

The structure and function of this section in its 1st stage determined that all studies and projects carried out at the Plant were part of such section and that all studies and projects would have the contribution of every section's experts and of the central body.

Concurrently with the Battelle recommendations, the "Studies and Projects" started-up at CUF, its first purpose being the organization of the industrial reality, but having its horizon in the future development of products and processes. Once the routine problems of the manufacturing plant were identified and adequately controlled, in the first stage, the routine work would be otherwise ensured and the engineers would be freer to do their creative work. However, the technical staff at CUF-Barreiro was still insufficient and it was taking too long to get more engineers for the Zones, which was necessary both for its expansion and for feeding the service concerned[5]. So, the training of experts for the "Studies and Projects" was going on at slow pace.

The following years were characterized by a close cooperation between the different Zones and the "Studies and Projects". As evidence thereof both established and held monthly meetings with the double purpose of evaluating the progress of the various projects and studies under execution and of raising the discussion of problems of common interest. Therefore, at this moment it is relevant to investigate into further detail of the Zones and their problems, taking as example the one that can be of greater significance at that time, from a technological point of view, at CUF-Barreiro.

---

[5] As an example of initial recruitment, a reference should be made to the transfer from the Acids Zone of the graduate technician Orlando Pedro, who began to act with the purpose of standardizing the equipment and reducing the variety of spare parts, under Eng. Luís Alves' guidance, at the subsection Equipment Standardization, that was being organized at that time in the Studies and Projects Section. Edgar Wahnon. Memoranda of March 10 and 11, 1953. Proc. 215, Studies and Projects. Former DQIM (inorganic Chemicals and Metals Division) Documentation, CUF. CUF/QUIMIGAL Archives.

Fig. 7: Main body of the “Studies and Projects”. Experts provided solutions for Zones common problems. Periphery –All the studies and the projects related to each Zone activity. By the middle of the 1950s, several Zone Study Centres were already created, and the Zone’s specialized personnel managed the specific problems of their own.

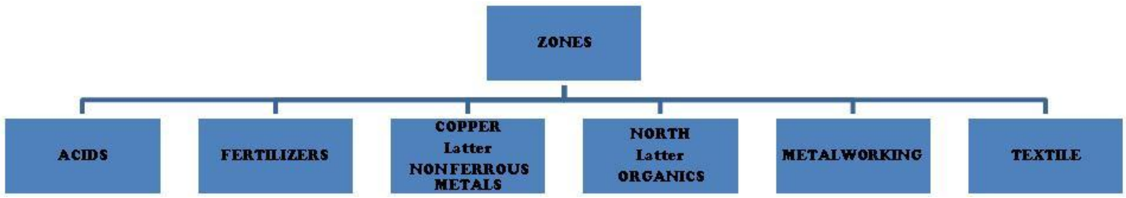

Fig. 8: CUF-Barreiro “Zones”. “Zones” provided industrial performance and also technical services; The technical services of each Zone were performed by the “Studies Centre”.

The Acids Zone

By analyzing the replies to a request made by Battelle, in 1954, about every Zone of CUF-Barreiro, aiming at being provided with relevant information on each one of them, namely in terms of productions, technologies and more pressing problems, it is possible to characterize the paradigmatic case of the Acids Zone.

In 1954, the Acids Zone defined its activity as follows:

A – Productions and consumptions

1. Manufactured products and respective annual productions – a) sulphuric acid at several concentrations, including “oleum” with 20% free SO_3. Total annual production of about 130,000 (metric) tons expressed as monohydrate (MHS); – b) Sodium sulphate: 3,000 tons; – c) Hydrochloric acid 29.7% to 33.3%: 5,100 tons.

2. Internal and external consumptions – a) Sulphuric acid, 75.5% for internal consumptions – 1.1% Acids zone; 70.6 % Fertilizers Zone and 3.8 % Copper Zone; 24.5% for external consumption. – b) and – c) 1,360 tons each, supplied to different customers.

3. Raw materials used: cupriferous pyrites from the Portuguese mines of S. Domingos, Aljustrel and Lousal, both in sulphuric acid manufacturing plants by the chamber process and in sulphuric acid plants by the contact process; marine sodium chloride (from Tagus and Sado rivers); ammonia liquor at 25% supplied by UFA (*União Fabril do Azoto*, an affiliated company of CUF).

4. Manufacturing plants: Pyrite milling plants (2); Chamber process plants (8); Acid contact plants (2); Acid dilutions (2); Sodium sulphate and hydrochloric acid plant; Sodium sulphate milling plant.

B – By-products

Purple ore – about 74,500 tons per annum; electrostatic precipitator (ESP) dust with 40% lead content (from Contact Plant no. 1) or 12% lead content (from the remaining sulphuric acid plants) – about 2,200 tons per annum, in total of the acid plants considered; selenium sludge (≈ 3% Se) obtained from the electrostatic precipitator (ESP) cooled gas of Contact Plant no. 2 – 10 to 15 tons per annum; lead sludge, in variable compositions, from tank and chamber cleaning.

C – Types of research

Research to be performed by Zone 9, of interest for the Acids Zone:

A. Studies and chemical tests, including "standard" tests for defining the characteristics of the materials used in the Zone (ceramics, plastics, special steels, etc.), search for interesting elements in by-products, corrosion studies, etc.

B. Studies and technological tests on production problems, with design and drawings for modification of the presently existing plants.

C. Technical information retrieval, standards and laws relating to industries and productions of the Zone, in order to ensure know-how updating and to enable the modernization of the manufacturing plants.

In 1955, the list of studies and projects carried out by the experts of the Acids Zone, which embraced the following subjects – furnaces; – sintered raw pyrites, silica, copper, lead and zinc content; – carob bean industry; – Contact Plant no. 3 (preliminary study); – removal of lead from pyrites during roasting; – plants with Towers; – Acids Zone office; – automatic beating of electrostatic precipitators in the Chamber-process Plants; – change in maintenance of burnt pyrite in the Chamber-process Plants and in Contact Plant no. 1; – identification of the supply of milled pyrite to Groups 1 to 4; – utilization of Copper Metallurgy gas; – de-dusting system of Symons Milling unit; – shipment and auxiliary units of Contact Plant no. 2; – revamping of the cleaning system of Contact Plant no. 1; – sodium sulphide, – sodium sulphate; – iron chloride; – ammonium chloride, reveals the evolution achieved within just a few years.

The studies and projects proceeding from this Zone are an evidence of a new endogenous ability to reflect on, to approach and treat the technological problem by the Plant technical staff.

The «Studies and Projects» and the study centres of the zones

In March 1956, the "Studies and Projects" were made up by following sections: SP – Technology; SP – Materials; SP – Documentation; SP – Laboratories; SP – Codification and Standardization and SP – Drawing Room. These sections represented the spheres of action of the experts before the remaining CUF Departments. In October of the same year, a new structure of the SP (Studies and Projects) presents 3 different sections: 1. Studies and Projects; 2. S.P. – Drawing Room; 3. S.P. – Codification and Standardization. According to this new document, the first one was "the basis for the Future Research Institute of the corporation". Its aim was "the accomplishment of the chemical process project as well as the resolution of all matters related with that project stage. It embodied the former fields of (Chemical) Technology, Materials (and Corrosion) and Laboratories, and it had in view the creation of new ones: Mechanical Technology; Chemical Mechanics; Instrumentation and Control; Technical-Economical Field; Statistical Control. Additionally, a regulation proceeding from the Technical Management Department of CUF (Headquarters –Lisbon) determines how the corporate studies and projects shall work and presents not only one, but two entities that have legitimacy to carry them out, the "Studies and Projects" (already existing with a structure of its own) and the Study Centres (newly created, directed by the head of the Zone). At this time there are five Zones that developed a Study Centre: Acids; Fertilizers; Copper; North and Textile. It can be assumed with some consistency that the Zone experts, instead of going to the "Studies and Projects" in order to establish there their activity, remained linked with the zone structure, increasingly defining a study and research territory of local scope. The demarcation, here in evidence, between the Zones and the "Studies and Projects" occurred only three years before the changing of the latter into Research Centre (1959). Engineer Luís Alves used to tell that in 1956, following these separations, "the 15 years war" had begun because the corporate policy had determined that every "high level" research should be reported solely to this body, which was first called "Studies and Projects" and then Research Centre. In the Zones (or Divisions) nobody felt that advanced research was not being carried through, therefore no one asked the central body for studies and the latter began to live on work performed by external entities.

The occurrence that took place in 1957 regarding the construction of the third contact-process sulphuric acid plant, the "Contact Plant no. 3" makes clear this superposition resulting from some badly settled confusion of duties: in March, the Acids Zone, having its Study Centre under full organization, and concerning the technological calculation of said plant, suggests to CUF Technical Department that this Centre be provided with the necessary means so that, in the future, CUF might have the capability of carrying out the project of sulphuric acid plants. With these means it would be possible to thoroughly analyze the plants and to recover a set of data, upon which the technological calculation of a furnace, of catalysis or of an absorption tower could be based. Strengthening the technical personnel of the Zone was obviously one of the prime factors to attain this capacity: a new chemical engineer, in order to discharge the current one from his tasks at the production part, an analyst and an assistant who would be the staff of the Acids Zone Laboratory to be set up too. The reply of the Technical Department to this *memorandum* enhances the intent to proceed to the strengthening of the technical personnel of this Zone, but it stresses that the Technological Calculation is reserved to the experts of the Studies and Projects and not to the Study Centres. Thus, "in these terms", that Study Centre should concern itself mainly with specific problems of the Zone which, in this case, is skilled to manufacture Acids. To do so, it must avail of a small Zone Laboratory and other facilities, but it is not necessary that it includes a department or an individual specialized in Technological Calculation, who would not even have enough work for a full time occupation (…) we kindly ask you to request the Studies and Projects to perform the Technological Calculation for Contact Plant III and to provide them with the necessary means, so that such calculation may be made within a short time as required".

By the end of 1958, following studies were being performed, among others, by the Study Centre of the Acids Zone: Preliminary studies - Study of documentation on fluidized bed furnaces (DORR), Study of documentation on turbulence furnaces (BASF), Study of documentation on plants with towers, economic Study aiming at the replacement of the Chamber-process Plant, Study of hydrochloric acid absorption, Study of the possibility of manufacturing potassium sulphate in the existing furnaces, Viability Study of titanium dioxide manufacture in Portugal; Study of lead recovery in the form of concentrated dust, Study of the operation of electrostatic precipitators (ESP) of the Chamber-process Plants.

The documentation

Until 1954, the circulation of technical and scientific information at Barreiro industrial complex consisted of a bulletin containing the abstracts of the 50 technical-economic magazines then subscribed by CUF, of some basic books and of the *Chemical Abstracts*. The development imposed by the structure of the production and of the technical work gave rise to the creation of a Documentation Service. The first activity of this Service was purchasing books with the purpose of setting up a Library. From that time on, the Bulletin that formerly circulated in the Plants published *abstracts* of the most interesting articles and transcribed the summary of the received books. The documentation soon assumed such proportion that, in 1956, a classification system was adopted, in this case the Universal Decimal Classification, UDC. Simultaneously the number of magazine subscriptions increased to 200 and the manual selection of information became unbearable. The FILMOREX equipment was then purchased for keeping records and selecting articles.

The Documentation Service was an integral part of the Studies and Projects and cooperated with the Zones (which also had a library of their own) in various fields, such as the search for and dissemination of technical and economic information, works requisition and lending, translation of articles and correspondence.

Conclusion

In 1959, the wide and important reorganization in progress at the corporation, which created the Divisions, these being entities which gathered the commercial part and the manufacturing plants part, extinguishes the Technical Department and creates the Research Department. This Department aggregates the various CUF centres: Project Centre; Documentation and Patent Centre; Standardization Centre and Research Centre, the latter being the result of the "Studies and Projects" extinction. Alongside of this separation, the great technological achievements at CUF-Barreiro in the decades of the fifties to the seventies of the 20th century always had the close cooperation of the Zones experts.

The structural changes at CUF-Barreiro which will still go on during the decades of the sixties and seventies of the 20th century will sometimes lead to modifications in the name, constitution and even, to some extent, in the scope of the Study Centres of the decade of the fifties. However, the importance of that "technological movement" and the significance assumed by the research and development activity performed is a fact that deserves much more "Studies and Projects".

RUSSIA AND MONGOLIA: TRANSFER OF SCIENTIFIC KNOWLEDGE IN POLITICAL CONTEXT (1920S)

Tatiana I. YUSUPOVA
Institute for the History of Science and Technology, Russian Academy of Sciences –St. Petersburg Branch, RUSSIA
ti-yusupova@mail.ru

Abstract

Russian-Mongolian scientific contacts began in the middle of the 1920s. It was impossible for Mongolia –just until recently a feudal-theocratic country without any system of secular education– to start organizing of national scientific institutions without foreign support. Taking into consideration all historical and political factors, the first possible candidate for granting such a support was the Russian Academy of Science (RAS).
The latter had an interest of its own in the exploration of Mongolia for several reasons: further explorations in frontier regions; or systematization of materials, having been previously collected during several Russian expeditions to Central Asia and then located in Academic institutes. The intentions of the Russian scientists, interested in further explorations of Mongolia, and the support of the Mongolian Scientific Committee coincided with the geopolitical situation in that region and the striving of the Soviet government for obtaining political authority there. That is why RAS' initiatives were supported by the government.
Russian-Mongolian scientific contacts took various forms, such as: joint Russian-Mongolian expeditions and publications of collected data, support in establishing a national museum in Mongolia, exchange of scientific editions, formal visits of RAS officials to the Mongolian Scientific Committee, training of young Mongolian specialists in Russia, and so on. They developed from the gratuitous aid on the part of Russia to the bilateral party relationship on the basis of various agreements and conventions in which both countries took part. Their format, content and intensity varied due to the international status of Mongolia, the nature of Russian-Mongolian relations, and the internal political situation in both countries. Today, according to many researchers, an ideological component left the academic interaction of both countries giving place to national interests.

Modern science emerged in Mongolia in the first half of the 20th century. Russian scientists played a key role in this process. They transferred the European system of scientific knowledge, ideas and research methods to Mongolia, helped create scientific communities, research and educational institutions. The fact that Russian scientists became a kind of "donors" was based on a complex of historical reasons and an undefined international status of Mongolia in the first place.

The independence of Mongolia, declared in 1921 in a unilateral order from China, was officially recognized only by Soviet Russia, as for Soviet Russia, Mongolia was an important strategic partner in the Far East and a buffer between

Russia and China[1]. Due to this fact, Russia provided Mongolia with various aids aimed at establishing the economy of the country, research and development of its natural resources, formation of national state institutions, and fortification of defensive capacity. An important element of the Soviet foreign policy was also a comprehensive support to the growing scientific potential of Mongolia.

It was impossible for Mongolia, which only a few years earlier was still a feudal-theocratic country without any system of secular education, to start organizing national academic institutions without foreign support. The first possible candidate for granting such a support was the Russian Academy of Sciences (RAS) due to its geographic neighboring and the deep historical connections between Mongolia and Russia.

In November 1921 the first scientific institution was founded in Mongolia, it was a Scientific Committee. It was created on the basis of typological features of the Russian Academy of Sciences and in its activity it made use of the Russian Academy's experience.

In particular, following the example of Western-European and Russian academic societies, one of the initial steps of the Scientific Committee was the foundation of a Natural History Museum as a first step towards accumulating knowledge about nature and history of the country and as a research laboratory. Replenishment of the Museum funds became a must for all foreign expeditions in Mongolia. The Scientific Committee actively developed another traditional form of activity for Communities, electing foreign scholars as honored members in its rows[2].

For Mongolia, which had stepped on a path of radical social changes, it was vital to have the "flavouring of Western science". Due to this task, the officials of the Scientific Committee turned to RAS with a request to send specialists in different fields to give lectures, as well as books for organizing a scientific library. Throughout the 1920s and the 1930s Russian specialists in various areas worked in the Mongolian Scientific Committee.

The second most important task which the Mongolian Government had set for the Scientific Committee was the reconnaissance of natural resources of the country. Limited funding, poor basic material means and a total lack of specialists did not allow expanding research activity in this field. Russian scientists were interested in studying Mongolia as vast materials on Central Asia had been accumulated in Academic institutes and museums by that time, and for their systematization it was required to continue research in the neighboring country. Taking into account the Soviet Government's interest in strengthening its political influence in Mongolia, RAS authorities initiated a discussion on providing Mongolia with scientific help.

They stressed the necessity to develop previous investigations not only because of scientific, but also economic and political advantages for Mongolia and the Soviet Russia. The arguments provided by the academic society turned out to be convincing and the Government ordered to organize a large-scale research expedition to Mongolia and to support the Scientific Committee. Political factors also played an important role in the decision: one of the top governmental officialswho supervised this project in the Soviet government, N.P. Gorbunov, emphasized in his speech that it was necessary to conduct research in Mongolia for "cementing our friendly relations with the Mongols and for the penetration of our political influence in Mongolia"[3].

As a result of the discussion the special Mongolian Commission was formed, which was to lead research works in Mongolia. Employees of the Mongolian Commission provided the Scientific Committee with a great help in organizing research activity, training national specialists and accumulating scientific knowledge in Mongolia[4].

It should be noted that for more than 60 years (1930-1990) Russian-Mongolian relations were defined as relations between a patron and a satellite. However, throughout the 1920s Mongolian statesmen resisted the Bolshevik's ideological influence defending a national way of development for their country[5]. It resulted in correcting the directions of scientific support provided by RAS. That was the reason why friendly relations with the Scientific Committee were a priority for the Mongolian Commission.

The tasks that the Soviet government set for the Mongolian Commission varied according to the foreign policy goals:

1925 - Academic research of Mongolia, which was necessary for "penetration of our political influence in Mongolia";

[3] State Archive of the Russian Federation. F. 5446. Op. 37. D.10. P. 67.

[4] Yusupova T.I. M*ongol'skaya komissiya Akademii nayk. Istoriya sozdaniya i deyadel'nosti (1925-1953)* (The Mongolian Commission of the Academy of Sciences of the USSR. History of Organization and Activities. 1925-1953). SPb., 2006.

[5] Barkmann U. *Geschichte der Mongolei oder die Mongolische Frage: die Mongolen auf ihrem Weg zum eigenen Nationalstaat*. Bonn, 1999; Murphy G. *Soviet Mongolia. A Study of the Oldest Political Satellite*. Berkeley, 1966; Rupen R. *Mongols of the Twentieth Century*. Part. I. Indiana University, Bloomington, 1964.

1926 - “Research of Mongolia is a kind of duty for Soviet Russia, Mongolia’s closest neighbor that is equipped with the necessary means for research”;

1930 - “Our [Soviet Russia’s] duty is to help developing and improving economic and cultural construction in Mongolia”;

1947 - It is necessary “to build a foundation for practical steps of the Mongolian Government in the field of improving economic and cultural construction”.

It should be noted that the ideological and political motivation of Russian expeditions in Mongolia did not affect their methods and academic credibility of research, as it is demonstrated by the reports of the expeditions. The style of the reports, by the way, conforms to established norms of academic literature, with its characteristic logic of argumentation.

The period of 1925-1933 became the most prolific one in the activity of the Mongolian Commission. During these years 41 expeditions were organized where more than 30 people took part. As a rule, members of the Mongolian Scientific Committee took part in Russian expeditions, which was a unique opportunity for them to broaden their professional horizons. The expeditions led archeological, botanical, geological, geochemical, zoological, soil and geographical, ethnographical and linguistic research. Moreover, all research results obtained by the expeditions were published in the issues of the Mongolian Commission and were handed over to the Mongolian Scientific Committee.

The activity of the Mongolian Commission closely followed legal regulations of international interaction and was subject to treaty engagements between the academic societies; however, until 1929 they were not official. The first formal treaty between the Academy of Sciences and the Mongolian Scientific Committee was signed in 1929. This agreement was aimed at eliminating all legal misunderstandings if they were to happen in the work of research expeditions in Mongolia.

The preparation of the treaty highlighted various contradictions between the Russian Academy of Sciences and the Mongolian Scientific Committee. For the Russian Academy of Sciences, as a rule, research work in Mongolia was a basis for further theoretical studies. The Mongolian party was more interested in the works of applied character, especially in economic and agricultural fields, which would allow realizing plans of quick sociopolitical reorganization of the country. The reorientation of research programs of the Mongolian Commission towards salvation of economic problems begun in the 1930s, as a result of intense state and ideological control of research activity in Soviet Russia. Soil, geological, geochemical, agricultural development and –first and the basis of Mongolian’s economy– cattle breeding became a priority in the activity of the Mongolian Commission in the following years.

In 1932 a sharp reduction of expedition research happened due to the aggravation of the internal situation both in Mongolia and in the Far East. And so, in June 1935 the Political Bureau of the Bolshevik party took the decision to suspend the expedition and other activities of the Mongolian Commission.

Since then and up to the Second World War, publishing became the main focus of the Mongolian Commission. The issues published by it became study guides in Mongolian nature, history, language, literature and economy. All materials published were handed over to the Mongolian Scientific Committee and later on they became textbooks on Mongolian history and nature for the next generation of Mongolian researchers. In various Russian academic institutions a vast material, a database in its own way, is accumulated as a result of research work conducted within the framework of these cooperative activities.

'GERMAN SCIENCE' IN PORTUGAL, 1933-45

Abstract

The period in analysis raises several crucial questions which revolve mainly around the Science-Society-State triad. This particularity calls for an historical analysis that takes as its cornerstones the relations between: 'Science, Culture, State (Nation) and Society', 'Science and Nationalism' or 'Science and Propaganda'.
The National-Socialist State takes advantage of Science, in an ideological and propagandistic manner and brings new nuances into the institutional relationship between Science, Society and State that had, at least since the end of the 18th century, appeared quite steady and balanced.
Science in National-Socialist Germany –and the term 'Science' should here be understood in the broadest sense of 'Wissenschaft', including both 'Naturwissenschaften' and 'Geisteswissenschaften'– has been the object of several studies. These have been mostly developed within a German historiographic framework and consequently, mainly concerned with demystifying internal structures and problematics. They therefore paid less attention to the circulation (and influence) of 'German science' outside Germany.
This paper will try to bring into focus the circulation of Science and Techonology between Portugal and Germany of that period, thus tentatively providing a wide and general picture of the persons and institutions involved in a complex –social, scientific, political– network of influence.

> «[...] the bomb has persuaded historians that they must take some account of the role of science»
>
> (Kuhn 1977: 132).

One will hardly find a moment in the History of Mankind which so incisively enlightens Bacon's famous aphorism *Scientia potentia est* as the period between 1933 (or 1939) and 1945 does. Sure enough, the fact that World War II was decided rather by laboratory research than bravery on the battlefields meant a global (and, in a way, radical) change of perspective of Science as well as of History. 'German Science' is undoubtedly (on both sides of the Atlantic) at the heart of this transformation.

This period raises several crucial questions which revolve mainly around the Science-Society-Politics triad. This particularity calls for a historical analysis that takes as its cornerstones the relations between:

- Science, Culture, State (Nation) and Society
- Science and Nationalism
- Science and Propaganda

The National-Socialist State takes advantage of Science in an ideological and propagandistic manner and brings new nuances into the institutional relationship between Science, Society and State that had, at least since the end of the 18th century, appeared quite steady and balanced. One needs only to remember, for instance, the interdiction of the periodical *Nature* in nazi Germany (cf. Rügener 1938).

Science in National-Socialist Germany –and the term 'Science' should here be understood in the broadest sense of 'Wissenschaft', including both 'Naturwissenschaften' and 'Geisteswissenschaften'– has been the object of several studies (cf. among many others, Kuhn et al. 1966, Erdmann 1967, Meinel/Voswinckel 1994, Hausmann 2002 or Cornwell 2003). These have been mostly developed within a German historiographic framework and therefore mainly concerned with demystifying internal structures and problematics. Hence less attention has been paid to the external use that nazi propaganda made of an internationally recognized and reputable tradition: Science produced in German academies, universities and laboratories.

The 3-year research project, that this paper intends to briefly present, aims to bring into focus the many ways of representing 'German Science' in Portugal between 1933 and 1945, be it in a more political field (where the scientific publishing was overshadowed by the propagandistic and ideological one) or in the more scientific and institutional field of specialized interaction, with 'German Science' influencing the building of several academic disciplines in Portugal (from Ethnography to Engineering, not forgetting the Philologies). The analysis will therefore focus on:

- scientific works of German authors published in Portugal;
- exhibitions (at the National Library in Lisbon, for example); representations in media;
- institutional and non-institutional relations between both States in the academic and university context.

It is above all from the mid-sixties, i.e., 20 years after the end of World War II, that Germany begins to reconsider the role of science and technology as well as the role of universities during the nazi period. The essays written by Saller (1961) or Erdmann (1967) and the several public university lectures (*Ringvorlesungen*) that took place in some German universities (see for example Kuhn et al. 1966) can be considered without a doubt an important step towards a first outline of a History of Science in National-Socialist Germany. Other essays and collective works followed (Mehrtens/Richter 1980, Beyerchen 1980, Hermann 1982, Meinel/Voswinckel 1994, Hausmann 2002) until the more recently published book by Cornwell (2003) and the biographical lexicon by Gruettner (2004).

Most of these writings share a common feature: they are primarily concerned with inner landscapes and networks of the History of Science in Germany. They tend, therefore, to overlook the characteristic 'universalism' of the scientific enterprise –after all, one of the most important values of scientific knowledge–, neglecting the internationalisation of 'German Science' of that period, and thus not mapping a complex network of individuals, hybrid scientists/politicians, that take on these two different roles according to the particularity of their activity at a given time: as scientists they promote science 'made in Germany', they follow its theories and principles, devoting special attention to the newest German research developments; on the other hand, as political agents they encourage and decisively support the creation of institutional networks with German scientific organizations, or take German institutions as a model for creating new ones abroad.

If one understands propaganda as some kind of *Anxiety of Influence* (Bloom), as «the promotion of a State in foreign countries so that its national creations are *recognized* and *imitated*» (Giese 1939/40: 163, our italics), what is, then, the influence of 'German Science' in Portuguese contemporary Science? What are the parallelisms and affinities of these two national 'Epistemic Cultures'? Which of the scientific institutions were connected? How did those connections develop? What was the role of ideological and political propaganda in that exchange?

The project will basically try to deal with these questions and its possible answers focusing on the German-Portuguese networks of *institutions*, *individuals* and (academic) *disciplines* during this period.

Within the broader context of a European Cultural History of Science (and more specifically in the framework of a Portuguese-German relationship) some works have already been produced on prior phases of intense scientific contact, as in the Epoch of the Discoveries or in the 18th century (cf. among others Cardoso 2003, Carneiro *et al*. 2000, Carvalho 1996, Clara 2008, Opitz 1983); similarly, in recent years (and in the wake of an increasing attention to Portuguese History in the second half of the 20th century), more studies about the complexity of the relationship between these two authoritarian regimes have been published and become notable (cf. Rosas 1990, Louçã 2005, Rosmaninho 2001, Pimentel 2006, Loff 2008 or Torgal 1995). However, with a few exceptions (e.g.: Branco 2007, Branco/Barros 2007, Brito *et al*. 2002, Matos 1996 and 2005, Grossegesse 1996) those studies hardly explore in a systematic way the prolific scientific connections between the two States at that time.

In fact, and from a pure historiographic point of view, there exists a lack of studies about the relations between Portugal and Germany during the Second World War. In spite of the growing interest in this period (cf. among many others Rosas 1990 or Loff 2008) –which has to be understood against variegated and complex backgrounds, some of them national-mediatic, other historical-fictional (like the 'discovery' of the role played by Aristides de Sousa Mendes in helping Jews to flee from the Nazis or the novels that in more recent years have been staging Lisbon as a city of spies, some sort of European Casablanca)–, there are only a few authors that have written specifically about the subject (Louçã 2005, Medina

1998, Pimentel 2006, Torgal 1995). The dominant perspective remains however historical-political. There are also scattered papers focusing on the subject, but indeed Portuguese historiography has paid scant attention to the relations between Portugal and Germany beyond the stereotypical. The reason is well known: the German language continues to be an obstacle in the access to vital sources and bibliography.

Some of the essays mentioned before (Grossegesse 1996, Branco 2007 or Matos 2005), for example, can be seen as exceptions in this context as they analyze cultural institutions (respectively the *Mocidade Portuguesa*, the influence of German Ethnography in Portugal and the *Kraft durch Freude* travels in Portugal) from a much broader point of view, a point of view which, even though not being specifically concerned about scientific matters, allows us to catch a glimpse of the rich and densely interwoven networks established during the period in question between Portugal and Germany.

The image produced by the Portuguese historiography of science does not differ significantly from the one provided by Portuguese historiography in general. In fact, it shares the same silencing of certain areas of interaction and interface, whether because of political sensitivity rarely overtly discussed or the alleged linguistic obstacles. The bibliography by Tavares/Leitão (2006) or the essays collected by Nunes/Gonçalves (2001) have a few references to the international networking of science; the case of the German-Portuguese scientific relations between 1933 and 1945 remains until nowadays a kind of no man's land.

A proof of this State of the Art is the absence of any systematic approach to make an inventory of personalities and institutions involved in the interaction with personalities and institutions of Germany throughout the 20th century that would be a relevant contribution in order to recover a chapter of the patrimony of European History with repercussions still visible but rarely recognised in the present.

Focusing on the scientific relationships between Germany and Portugal between 1933 and 1945, this project aims to fill a twofold gap: firstly, the aforementioned one thereby contributing to the making of a European Cultural History of Science of that period; and secondly, the one that directly derives from it, that is: the deficit in research on the decisive and prolific scientific Portuguese connections to Germany.

THEMATIC MAPS AND THEIR CIRCULATION DURING THE NATIONAL SOCIALIST ERA

Petra SVATEK
Department of History, Universität Wien, AUSTRIA
petra.svatek@univie.ac.at

Abstract

This article will focus on the circulation on thematic maps developed in the Austrian part of the German Reich (called "Ostmark") during the National Socialist Era in the context of spatial research with the prime aim of addressing the exchanges of maps between political authorities, scientific institutions and various scientists of different disciplines. One focus of the lecture will be on the question of which institutions or scientists initiated this map-circulation. The hypothesis is that it depended on the research institution as well as on different research projects.

Spatial research established itself as a multidisciplinary science in the German Reich during the 1930s, in the process assuming great and above all political significance in the context of National Socialist ethnic and cultural area research and NS expansion policy.[1] Immediately after the annexation of Austria by the German Reich, spatially oriented research projects took off notably, combined with increased thematic map production. As early as per 13 April 1938, the Viennese geographer Hugo Hassinger (1877-1952) compiled a list of persons who might do valuable work for spatial research and spatial planning concerning the Ostmark on behalf of the "Reichsarbeitsgemeinschaft für Raumforschung" established in 1935.[2] Thematic cartography had the task of providing maps urgently required for spatial research. Yet cartography not only generated basic data for other research projects; it was in its turn also markedly influenced by spatial research. A review of map production from the Habsburg era into the 1940s shows that the input required for cartography increased enormously over time. This was chiefly due to the firm establishment of spatial research, since more and more statistical data were processed and visualisation methods grew in complexity.

Cartographic research focused on the one hand on the "Ostmark" and on the other hand, and increasingly, on South-eastern Europe. Spatially oriented cartographic studies helped to identify new areas for settlement and economic expansion as well as to plan resettlement campaigns for the benefit of the German Reich. Various statements in numerous, mostly

unpublished reports and letters clearly show that the thematic maps and other space-centred studies developed in the "Ostmark" were explicitly compiled with political intentions so as to contribute actively towards the National Socialist "Lebensraum" policy. The initiative in this did not always originate with National Socialist politicians and authorities, but often came from scientists themselves, who submitted their research findings to National Socialist politicians of their own accord, without having been constrained in any way to do so[3]. In this context, the circulation of both existing and newly produced thematic maps increased as well. The latter were mainly compiled by arts scholars and natural scientists as well as by cartographers forming part of various research groups.[4]

We can find four different sorts of map-circulation during National Socialist Era: at first the circulation between various scientists of different disciplines within a research society, second the circulation between different research societies, third the circulation between scientists and National Socialist authorities, and fourth the circulation between different political authorities. Most of the thematic maps were made by different research societies. In the Austrian part of the German Reich many research societies existed, which were situated mainly in Vienna. The most important were:

- *"Working Groups for Spatial Research"* at the Universities von Graz, Innsbruck and Vienna: They were part of the "Reichsarbeitsgemeinschaft für Raumforschung", the most important working group was the "Working Group for Spatial Research" of Vienna University, which was founded in autumn of 1938. This Working Group was headed by the geographer Hugo Hassinger[5]. Its research mainly covered the districts of Vienna, Lower and Upper Danube as well as South-eastern Europe.[6]
- The *"Southeast German Research Association"* was founded in 1931. It was one of six ethnic-German research associations set up mainly in Germany and concerned with the systematic study of the German ethnic and cultural territory. The map department was enlarged and headed by Wilfried Krallert (1912-1969), who had studied history and geography and was a NSDAP member as early as in 1934. In 1934 Krallert was also accepted into the SS, where he was assigned the rank of SS Untersturmführer in 1938.[7]
- The *"South-Eastern German Institute"* was established in Graz in April 1938. Its tasks lay on the one hand in observing the political events in Yugoslavia inasmuch as these concerned the interests of the German-language population and on the other hand in promoting German language and culture in Lower Styria (the northern part of today's Slovenia).[8]

In creating these thematic maps, the members of such research communities made use of both statistical data and existing maps provided by other scientists or various institutions. For example, members of the Working Community for Spatial Research of Vienna University repeatedly exchanged maps among each other when preparing the atlas of Gau Niederdonau (Administrative Region of Lower Danube). But maps were likewise swapped among institutions and research

[5] Hassinger was born on 7 November 1877 in Vienna as the son of a bank employee. In 1896 he began his study of Geography, Geology and History at Vienna University. After his doctors degree he worked as a teacher at different schools in Vienna and Moravia. In 1914 he was appointed to a lecturer at the Department of Geography at Vienna University. Starting from 1918, he worked as a professor at the Departments of Geography at the universities of Basel (Switzerland) and Freiburg (Germany). In 1931, he returned to Vienna, where he was appointed professor of cultural geography. Hassinger died on 13 March 1952 after a road accident. (Götzinger Gustav, 'Hugo Hassinger, 1877-1952'. In: *Mitteilungen der Geographischen Gesellschaft Wien* 96, Wien 1954, p. 149-176; Zippel Christine, 'Hugo Hassinger', In: Fahlbusch Michael / Haar Ingo, *Handbuch der völkischen Wissenschaften*, München 2008, p. 226-230; Svatek Petra, Hassinger, p. 290-311; etc.)

groups, e.g. between the Department of Geography of Vienna University and the "South-east German Research Association". The atlas of Gau Niederdonau was to provide a new starting-point for researching the Gau Lower Danube, assist spatial planners and create preconditions for the redesign of the German lebensraum for the purposes of the Third Reich. This cartographic work was deliberately organised in a multidisciplinary fashion by involving numerous scientists from many different institutions and fields of study.[9]

Yet not all maps received from other institutions were submitted voluntarily to the various research communities. This is e.g. documented by the map acquisitions of "South-east German Research Association" in the context of the Special Commando Künsberg. Here Wilfried Krallert and other members had the task of securing maps kept at various Belgrade institutions and considered significant for ethnicity research. During the operations conducted in mid-April 1941, they managed to obtain mostly very valuable cartographic material from the Statistical Bureau, the Institute of Military Geography and the University's Department of Geography, which all arrived in Vienna for further processing in late April. Inter alia, this material comprised the updated version of the map of Yugoslavia, formerly unknown in Germany (scale 1:25,000), maps of the country scaled at 1:50,000 and 1:100,000 as well as some remaining parts of the old map of Serbia (various scales); the latter was dispatched to the Main Cartographic Division XIV situated in Vienna. Initially, Krallert's task lay in evaluating the material captured and relaying it to different authorities for further processing. In due course, "South-east German Research Association" was upgraded to something resembling a distribution centre. Moreover, the cartographic department staff promptly made use of the data obtained to create in co-operation with the Department of Geography of Vienna University new ethnographic maps, which provided important sources for ethnographic "consolidation" by the SS and "Wehrmacht".[10]

The accuracy of the thematic data featured in these maps of the "South-east German Research Association" undoubtedly exceeded all older documents. Above all the highly detailed presentation style using an absolute value method permitted precise inferences regarding the distribution and size of the individual ethnic groups. In addition to describing the German, Slovak, Czech, Magyar, Slovene, Romanian, Bulgarian, Russian, Ukrainian, etc. ethnic groups, the maps also provided information about the Jewish population. For this reason, it cannot be excluded that they were used as sources for the deportation and annihilation of the Jewish people.[11]

After the Yugoslavian campaign, the contacts between "South-east German Research Association" staff members and SS Special Commandos continued from summer 1941 to 1944 in Russia through participation in the looting of several statistical offices and institutes of geography. Moreover, Krallert issued specific orders to seize the documents of various Leningrad institutions. In 1941, Krallert took part in these raids by joining forces with the "Einsatzkommando Nürnberg" (Mobile Commando Nuremberg) and looting a number of institutions in Kiev, Kharkov, Odessa, Simferopol and Sevastopol as well as, later on, in the Northern Caucasus region for strategic material. From this material, the staff members of the "Publication Office" e.g. developed a nationalities map of Crimea (scale 1:400,000) and an ethnographic map of the Caucasus region (scale 1:1.000,000). Inter alia, this material was used for the planned resettlement of ethnic Germans from the Volga and Black Sea regions.[12] These raids made Wilfried Krallert an excellent expert on Yugoslav and Soviet Russian cartography, whose know-how he drew upon e.g. in an article on the "Methodology in the Field of Soviet Russian Cartography" written for the "Deutsches Archiv für Landes- und Volksforschung"[13] in 1943.

Apparently, "South-east German Research Association" was ordered by the Foreign Office to produce new maps by combining older cartographic material with statistical data and to relay the output to other authorities and institutions of the German Reich and the South-eastern European states. These maps were then relayed to the Foreign Office, from where they were sent for example to the general staff of the army and air force as well as to the "Volksdeutsche Mittelstelle" (Ethnic Germans Welfare Office).[14]

Likewise, it seems that the thematic maps of the "South-Eastern German Institute" of Graz were mostly commissioned and circulated by political authorities. A key role in this process was assumed by the Graz-based geographer Helmut Carstanjen, who not only served as director of the institute but was also a member of the German-Croatian resettlement commission. This body was not only concerned with the relocation of Croatian nationals and ethnic Croatians from Lower Styria and the occupied zones of Carinthia and Carniola to the territory of the Independent State of Croatia, but also with the deportation of Slovenes and the resettlement of ethnic Germans.[15] It was likely in the context of this activity that the maps developed by the "South-Eastern German Institute" were circulated by him in co-operation with National Socialist institutions. Most ethnographic maps dealing with Croatia were created by the geographer Manfred Straka. One such example is the map "German Settlements in the Independent State of Croatia", which indicates the relative share of the German-language population in the administrative units of the country as well as the absolute number of ethnic Germans in its larger settlements.

However, scholars also made thematic maps available to NS institutions of their own accord without having been requested to do so by political authorities. These maps were mainly produced by staff members of the Working Group for Spatial Research of Vienna University. Many cartographic studies were not commissioned from the Working Group by outside parties; rather, its director Hugo Hassinger initiated politically relevant projects on his own, as is e.g. documented by the resettlement maps for ethnic Germans in South-eastern Europe. After Hassinger had been charged in 1939 by the "Verein für das Deutschtum im Ausland" (Association for Germans and German Culture Abroad) to develop his first study on the resettlement of ethnic Germans[16], he launched several initiatives in subsequent years to counteract the massive scattering of ethnic Germans in South-eastern Europe. His statement[17] in the proposal for a project on the "Re-arrangement of the Areas Inhabited by Ethnic Germans in the Inner Carpathian Region" clearly demands that science be prepared for whenever such resettlement issues should become pressing. This proves that Hassinger had intended the political slant of the study from the beginning without previous requests on the part of any authority or politician and was certainly willing to submit the study results. The same applies for the project on the "Status Quo of Ethnic German Groups along the Middle Reaches of the Danube". In both projects, thematic maps were planned partly in co-operation with ethnic German groups in South-eastern Europe; after completion, these were to be made available not only to the "Reichsarbeitsgemeinschaft für Raumforschung", but to political institutions as well.[18]

Another example is the atlas of Croatia, which likewise had not been commissioned by any political body. The atlas of Croatia was edited by Captain Alois Jaschke, who had mainly fought in Galicia and on the southern front during the First World War and later established a reputation through numerous scientific publications. The atlas was submitted for funding to the "Reichsarbeitsgemeinschaft" in the 1943/44 budget year as the research project "The economic basis of the independent State of Croatia". It was the objective of this study to provide for a general overview of Croatia's economic situation and social conditions as well as to examine the efficiency of the Croatian economy and its controllability. Hassinger submitted the atlas and other maps he had received from South-eastern European scholars to the "Forschungsstaffel zur besonderen Verwendung" (Special Research Unit, always referred to as "Forschungsstaffel z. b. V.") based in Neudorf.[19] Answerable to the Wehrmacht, the "Forschungsstaffel z. b. V." was set up in April 1943. Until the end of the war, it conducted terrain evaluations in unexplored or little known territories and also developed a number of maps in this context. The unit was composed of scholars from all disciplines of the natural sciences as well as seasoned military personnel (sappers, experts on armoured vehicles, aircraft and mountain infantry).[20] When Hassinger entered into contact with the unit, it was mainly busy with mapping parts of Dalmatia and hence found the material provided by him very useful. Due to the submission of these maps at Hassinger's behest, he was appointed to the "Working Community for Military-Scientific Terrain Research and Military Geology" in late 1944.[21]

[21] UAW, unpublished works done by Hassinger, box 18 (letter Hassinger to the "Reichsforschungsrat" 4. 12. 1944, letter Hans Spreitzer to Hassinger 12. 1. 1945).

Finally, I would like to draw attention to a map project involving staff members of multiple research groups: the atlas "The Danube-Carpathian Region". Collaborators in this project included not only scholars of the "Old Empire" and of Vienna University but also members of the Working Community for Spatial Research, "Southeast German Research Association" and "Southeast European Society". The new edition lobbied for by the Wehrmacht and commissioned by the "Welfare Office for Ethnic Germans" was to benefit the war policy of the period. Several sources document that the maps designed by Hassinger were sent by the geographer Egon Lendl (1906-1989) on behalf of the "Welfare Office" to the Stuttgart University of Agriculture, which co-ordinated the atlas project.[22]

Abstract

The communication will display a bibliometrical survey of personal bibliographical indexes of authors in different countries; an attempt will be made to select the science field. Universal Decimal Classification (UDC) index will be used to select records from the electronic catalogues of national libraries of the world: http://www.library.uq.edu.au/natlibs/ *(107 countries). Data will be collected only from the libraries which use UDC for systematising records. The UDC index 012 describes "Author bibliographies. Individual bibliographies" (*http://www.udcc.org*). Number of personal bibliographies will be compared to the general number of records in a catalogue of a national library of a country, so indicating the standing of a source in a country. Only records of books published after 1945 will be considered.*
The tradition of bibliographical indexes has a long history: from personal lists of scholarly works published in the first scientific magazines to a personal bibliography management software. The tradition of compiling an index of published works is well considered in academic world in many countries. Personal bibliography of a scholar, who initiated a scientific school or developed a certain trend in science, is a historical source, as it gives a chronological picture of science, as well as data about co-authorship.
Personal bibliographies are both issued as books and as internet sources, i.e. in HYLE (International Journal for Philosophy of Chemistry): "Bibliography on Boyle, –1940": 455 titles, compiled by the Robert Boyle Project (Michael Hunter); "Bibliography on Lavoisier, –1794": 1,179 titles, compiled by Panopticon Lavoisier (Marco Beretta); "Bibliography on Liebig, –1997": 242 titles, compiled by William Brock, etc.
The communication will compare data of published personal bibliographical indexes in different sciences with reference to the catalogue of the Vrublevskiai (Wroblewski) Library of the Lithuanian Academy of Sciences. Our tradition of 50 years in compiling such bibliographical indexes for famous scholars will be presented, as well as the discussion will be raised for the real need and importance of such activity. Some examples of indexes will be presented to the audience.

Introduction

Although the title question of this paper is not usually questioned by the historians of science, we shall try to evaluate the readiness of libraries for global surveys on the topic. More and more libraries launch electronic catalogues; try to open their holdings for interactive searches. The idea to include all holdings to electronic catalogues is a pursuance, though not easily achieved in some countries.

Author bibliography, as a result of bibliographical activity, is intended to register the works by and about a person; it gives a chronological picture of science, also data about co-authorship. For a scientific school, followers of historians of a particular branch of science, such bibliographical tool is usually the most valuable.

Historical background

Bibliography producers are usually libraries, scientific societies and very seldom private individuals. What encourages compilers to start and finally to complete such time-consuming, hard work? It's usually the inexorable desire to serve the community and save the labour of the followers by registering what was already achieved in the field. A primary bibliographic function is ***recording*** (enumerative) –listing individual items because, before books or articles can be studied, they must be known to exist. The vital factor in enumerative bibliography is that it should be *noncritical* and *complete*.[1]

This function has a clear distinction from a ***selecting*** activity, which turns technical activity of a compiler into a research work: select the best, relevant items from the infinite. Each single subject bibliography could be considered as a piece of subject history.

The tradition of bibliographical indexes have a long history: from author lists of scholarly works, published in the first scientific magazines to author bibliography management software.

Individual bibliographies are both issued as books and as internet sources, i. e. in HYLE (International Journal for Philosophy of Chemistry): "Bibliography on Boyle, –1940": 455 titles, compiled by the Robert Boyle Project (Michael Hunter); "Bibliography on Lavoisier, –1794": 1,179 titles, compiled by Panopticon Lavoisier (Marco Beretta); "Bibliography on Liebig, –1997": 242 titles, compiled by William Brock, etc.

Great attention was shown to the bibliographical practice of science history by the International Union of the History and Philosophy of Science, which launched the project "World History of Science Online (WHSO): databases of bibliographical and archival sources" in 2004.[2]

Methodology

Initially, bibliographical indexes are "(…) a systematic list of writings by a given author or on a given subject"[3]. Such bibliographical source usually serves as a source for the history of a given branch of science. The idea to give a world overview of author bibliographies was based on some brave presumptions to access:

1. National libraries intend to collect all published material of a country (nation).
2. Holdings of national libraries are accessed via electronic catalogues.
3. Records in electronic form are searchable using Universal Decimal Classification.

A bibliometrical survey of an author's bibliography was based on electronic catalogues held by national libraries. Criteria for investigation: the records of the electronic catalogue were based on Universal Decimal Classification (UDC). This classification system is widely used in research and academic libraries, but is not the only one. Its popularity is shared with Dewey Decimal Classification (DDC), the Library of Congress classification system (LCC), etc.

The UDC index 012 describes "Author bibliographies. Individual bibliographies"; it covers bibliographies of editions of, or writings about, the works of a particular author, or particular anonymous works.[4]

For the survey a list will be used of national libraries in 204 countries, arranged by the interactive website of the national libraries[5].

The number of national libraries with a homepage and interactive electronic catalogue will be compared, as well as the number of libraries using UCD for cataloguing.

---

[3] Bibliography *The Oxford Dictionary of Literary Terms*. Chris Baldick. Oxford University Press, 2008. *Oxford Reference Online*. Oxford University Press. Accessed on 15 March 2011 <http://www.oxfordreference.com/views/ENTRY.html?subview=Main&entry=t56.e128>.

[4] Author bibliographies. Individual bibliographies *Universal Decimal Classification.* Accessed on 15 March 2011, <http://www.udcc.org>

[5] *National Libraries.* Accessed on 15 March, 2011 <http://www.nationallibraries.org/>.

Survey

The vast variety of electronic catalogues proves the need of unified means of information search. The first interactive website of National Libraries has been made possible by a partnership between Texas A&M University Libraries and the National Library of Hungary. The objective of the website was to consolidate all existing websites of the National Libraries in 204 countries world-wide to a single platform. The survey turned out to have a double result: the results of author and subject bibliographies we inseparable.

After the survey the following data were identified:

A. National libraries with a homepage: 114 (56% of 204 countries).

B. National libraries with electronic catalogue: 79 (39% of 204 countries).

C. Electronic catalogues using UDC: 20 (25% of B).

D. Author and subject bibliographies, found in interactive electronic catalogues: 7882 (total in C).

Conclusions

Although only a pilot scanning of national library catalogues was performed, such survey should be acclaimed as under-resourced. The survey of the paper should be repeated with more detail, i.e. a questionnaire for a national library and a methodological advice of the WHSO. The project "World History of Science Online (WHSO): databases of bibliographical and archival sources" (The International Union of the History and Philosophy of Science) encourages bibliographical activity of member countries, and offers methodological support[6].

39% of national libraries maintain electronic catalogue.

25% of electronic catalogues maintain UDC.

Author bibliography is a must for each scholar; it should be compiled and made ready for publishing, so saving time and efforts to pupils and followers.

Since the global search is not appropriate for electronic catalogues of the libraries, special bibliographical data should be searched only from specialized databases.

A 'LANGUAGE OF MATHEMATICS': NEUTRALITY AS A FACILITATOR OF CIRCULATION DURING THE COLD WAR[1]

Helena DURNOVA
Masarykova Univerzita, Brno, CZECH REPUBLIC
helena.durnova@mail.muni.cz

Abstract

Computing and cybernetics are two fields with many intersections, which often leads to confusion. As Slava Gerovitch has shown (cf. From Newspeak to Cyberspeak*, MIT Press, 2002; 'Feedback of Fear', presentation at 23rd ICHST Congress, Budapest, July 28, 2009), cybernetics and its developments were heavily interconnected with politics on both sides of the Iron Curtain. Computing, on the other hand, was promoted on both sides of the Iron Curtain, and compared to cybernetics provided a more neutral ground for the exchange of ideas and concepts.*

The most neutral part of computing is connected with those parts that are close to mathematic: with programming rather than with the machines themselves. When programmers realised the benefits of sharing the outcome of their work, computer programmes or software, they opted for a programming language "as close as possible to mathematical notation". In my contribution, I will examine how the neutrality of such language –the language of mathematics– facilitated sharing practices, ideas, and results of the endeavour among computer scientists. Special attention will be paid to the spread of the ideas of the Dutch computer programmer Edsger W. Dijkstra and his Discipline of programming *and related works in the community of computer scientists in Czechoslovakia in the 1970s and 1980s.*

Introduction

In the early post-war period computing technology[2] emerged as a new field of science. Other such fields, emerging immediately after WWII, are nuclear physics[3] and cybernetics.[4] Their history, if not reduced to the technical details and

[1] This work resulted from my participation in the 'Software for Europe: constructing Europe through software' project led by Gerard Alberts, Universiteit van Amsterdam, funded as part of the European Science Foundation EUROCORES Programme "Inventing Europe". The research was funded by grant no. INE/07/E008 from the Czech Grant Agency (GAČR).

improvements, is told in the context of the Cold War. The transfer of computing technology in one direction, namely from West (or more precisely from the USA and the United Kingdom) to East, seems unquestioned. Given the origins and the potential of this new technology –this unique relation of thinking and doing[5]– in the military, the advances in the field were closely observed from both sides of the Cold War, with ideology debates and spies also involved.[6]

Analysing history of cybernetics in the Soviet Union, Slava Gerovitch speaks of computers as mathematical machines of the cold war.[7] Some sub-disciplines of computing were not under so much political pressure as others. This comparatively neutral sub-discipline, because theoretical and not bound to the provenance of the machine, is programming. Programming languages, emerging in the second half of 1950s, also grew out of the programmers' wish to share their work. Many of the computing people were advocating the use of a language "as close as possible to mathematical notation". The neutral nature of mathematics facilitated sharing the ideas and results related to theoretical programming.[8]

Very roughly, people active in computing in the late 1940s and 1950s can be divided into two groups: one with a background in electrical engineering and/or physics, and the other with a background in mathematics and/or logic. The first group's experience was of crucial importance in the design of computers, choosing the right components and material. The efforts of the second group were central to programming and implementation of specific mathematical machines as well as to thoughts on what could be automated.[9] In this paper, I analyse the circulation of ideas in these more subtle areas of computing that are connected closely to mathematics, in order to show that this relatively[10] neutral ground provided a relatively uncomplicated passage way for the transfer of knowledge between Western and Eastern Europe.

Cybernetics vs. computing

Debates about computing and cybernetics and their potential usefulness or uselessness were not limited to the Soviet bloc and the influence of ideology on science. Howard Aiken, for example, would not credit a machine with thinking;[11] von Neumann questioned the expectation that a machine made of unreliable elements would work reliably.[12] The term *cyber* has been closely intertwined with computers and their use since the beginnings of the disciplines in the 1940s, which was not just a matter of confusing the two because of personalities like John von Neumann,[13] who contributed to both. Cybernetics in the strict sense, i.e. the science based on comparing the feedback mechanisms in living organisms and in machines, was initially rejected by the ruling party in the Soviet Union, and hence also in other Soviet-bloc countries. As Gerovitch describes

in detail,[14] the situation changed around mid-1950s. Ernest Kolman's article 'What is cybernetics' is often cited as being the one of the keys in this change. The article, published in *Voprosy filosofii* in 1955,[15] triggered changes towards warm reception of cybernetics also in Czechoslovakia. In Prague, cybernetics was discussed by a group of researchers publishing under the pseudonym K. Vasspeg. The name *K. Vasspeg* was composed of the initial letters of the researchers' surnames: *K* stood for Jiří Klír, *Va* for Milan Valach, *S* for Spiro, another *S* for Petr Sehnal, *Pe* for Pelikán, and *G* for Ján Gecsei, all of them young computer researchers[16] participating in the design of Czechoslovak computers. Hence, the connection between computers and cybernetics appears even more strongly.

In contrast to cybernetics, computer was regarded as a tool, as electronic computers were expected to substitute human computers. By doing so, mathematical machines would free the hands and minds of people, thus helping the advancement of knowledge. In that sense, the purpose of computers was the same as in the West. As Slava Gerovitch has shown,[17] cybernetics and its developments were heavily interconnected with politics on both sides of the Iron Curtain. Computing, on the other hand, was promoted on both sides of the Iron Curtain and compared to cybernetics, provided a more neutral ground for the exchange of ideas and concepts.[18]

Computers as a research aid

The effects of the Cold War situation on the development of computing in Czechoslovakia cannot be reduced to the simple problem of the impossibility to freely purchase computers or spare parts for them. The Czechoslovak computer Antonín Svoboda spent most of World War II at MIT in Radiation laboratory, designing analog devices. Upon his return home, he wanted to teach mathematics at the technical university in Prague, although his background was in electrical engineering and physics. Svoboda's activities in computing in Czechoslovakia included the military (VTU), the production of computing machines (Aritma), and the theoretical design of computers. In this paper, the last of the three is the point of entry.

Svoboda presented his first proposal for an electronic digital computer in the Research Institute for Mathematics of the Czech Academy of Sciences and Arts upon his return from the UNRRA-sponsored trip in September 1947.[19] The relations between computing and mathematics in Czechoslovakia were institutionally quite strong: the Czechoslovak Academy of the Sciences, established in November 1952, had its Mathematical Institute, part of which was the department for information processing machines.[20]

In the early 1950s, Antonín Svoboda, the designer of the first Czechoslovak computers, urged researchers to find problems that can be fruitfully solved by computer.[21] The computer was developed in the vicinity of the Mathematical Institute of the Czechoslovak Academy of Sciences, which would also supply tasks for the computer and in fact were relying on the computer to carry out the tedious calculations connected e.g. to the construction of dams.[22] Svoboda's plea seems to turn the relation upside down by saying that computers need work, but interpreting his plea in this way would be derogatory. Rather, the mutual interaction between mathematicians and the emerging field of computing is a general feature: departments of applied mathematics and laboratories for computing soon grew into departments *per se*.

The strategy of the Czechoslovak Academy of the Sciences was to catch up and overcome, and thus contacts with researchers in the West were encouraged in the sciences and in technology,[23] unlike in the humanities. Furthermore,

[23] Masaryk Institute and Archive of the Academy of the Sciences of the Czech Republic, collection I. sekce ČSAV, box 21, folder 68.

science and technology was officially in the centre of attention.[24] Researchers from the Institute for Mathematical Machines profited from this encouragement and from their director's contacts within the computing field abroad. Similarly, foreign researchers were invited to Czechoslovakia: H. Greniewski,[25] L. Łukasiewicz, and R. Marczyński from Poland, N. J. Lehmann from East Germany,[26] and also W. Hoffmann from West Germany.[27]

In October 1955, a major international gathering[28] of computing people took place in Darmstadt.[29] This was co-organised by GAMM (Gesselschaft für angewandte Mathematik und Mechanik) and VDE (Verband deutscher Elektrotechniker) in co-operation with DMV (Deutsche Mathematikervereinigung). The local organizer was Alvin Walther,[30] director of the Institute for Practical Mathematics in Darmstadt and the conference was attended by over 500 researchers from 15 countries. A fifth of the participants were from abroad, twenty of the contributions were devoted to developments in Czechoslovakia,[31] the Soviet Union,[32] Sweden,[33] the Netherlands,[34] and other European countries.

In their keynote lectures, Alston Scott Householder, Heinz Rutishauser, and Howard Aiken all emphasized the connection of mathematics and computation. According to Householder, mathematicians had to learn something that Gauss did not know, namely programming.[35] Rutishauser further pointed out that mathematical formulation was the first step in solving a problem through automatic computation.[36] Aiken brought attention to the single objective of mechanization of numerical analysis which stood at the beginning of the modern efforts to construct large computers.[37] In short, the Darmstadt conference on electronic digital computers and information processing could also be presented as a mathematical conference.[38]

In September 1957, a member of the above-mentioned IPM, Walter Hoffmann, came to give lectures[39] on the development of electronic computing machines with regard to the situation in West Germany.[40] The lectures were co-organized by the Union of Czechoslovak Mathematicians and Physicists and two institutes of the Czechoslovak Academy of Sciences: the Mathematical Institute and the Institute for Mathematical Machines of ČSAV, which underscores the interest of mathematicians in the development of computing.

Programming computers

In the 1950s, it became clear that giving exact instructions (which later crystallised into programming) to the computer would be a tiring, time-consuming, and error-prone job, and this was not just because machine code was different for different computers. Methods in numerical mathematics had been developed for human computation and other kinds of approximation and their transfer to automated computation was not as straightforward a business as it might have seemed.[41] Olga Pokorná[42] for example, encountered difficulty when implementing an algorithm that should have stopped when the result was zero. However, this zero was too loosely defined: the mathematician using the method would know when to stop, while the computer never arrived to zero, but to some very small number, hence the program would run infinitely. In short, what is now known as basic algorithms to any computer programmer had still to be developed.

The ponderings about the difficulties and tediousness of programming led to the development of automatic coding, programming programs, and systems of automatic programming. Roughly speaking, all the preceding notions refer to the same thing: as the new field developed, programming was done separately for each computer in its machine code. Also at conferences, people would report about the work done in their centre and seldom refer to work of others, as it was not directly transferable.

In Czechoslovakia, the way of giving the instructions to the computer was called *instruction sequence* or *instruction network* since the early 1950s until the early 1960s, when the term was substituted with the words *program* and later *program* or *software.*[43] These two concepts differed in their complexity: while instruction sequence ordered the instructions linearly, instruction network allowed for branching and loops. Thus, in an instruction network, the decision to take one or another branch could be taken in the course of the computation described by the same instruction sequence. Similarly, certain parts of the computation could be repeated in a loop. Like in the USA, Britain, Germany, and the Soviet Union, researchers in Czechoslovakia soon realised that there were intellectual and boring parts of programming.

Without any significant theoretical work having been conducted in the automation of programming in Czechoslovakia, the emergence of ALGOL 60, which promised to become the universal medium for exchanging programs, was warmly accepted upon the publication of ALGOL 60 reports in *Numerische Mathematik* and *Communications of the ACM.* The translation of the full ALGOL 60 report into Czech was finished in 1963 and was a joint work of a group of researchers from the Research Institute for Mathematical Machines. It consisted of three parts: the translation as such was preceded by an introduction into programming and followed by a note on compiler construction. The book soon sold out, to the regret of textbook writers. Textbooks on programming in general and ALGOL 60 in particular began to appear in Czechoslovakia in the early 1960s. Every school and every computer was to have an ALGOL compiler.[44]

Translations and reports

As stated above, the flow of computing technology is usually presented as West-East transfer. While this is the case for the actual machines, the ideas about machines and their use moved across the borders more easily. Translations of Western literature into Russian is well known: many of these translations included references to the Russian translations of the works cited in the original and sometimes, the translators would add new Russian references. The US-based Association for Computing regularly reported about computing technology in the Soviet Union as well as in Central and Eastern Europe, the first report appearing in the *Journal of ACM* in 1956.[45] When the monthly *Communications of ACM* was launched, reports from trips to the Soviet bloc countries appeared there regularly.[46] Despite this, reports published in the 1980s reveal concerns with export of computers[47] and software.[48]

ACM*, vol. 2 (1959), no. 12, pp. 1-2; Willis H. Ware, ed., Soviet

The development of programming in the Soviet bloc was observed in the West and vice versa: Ershov's 1958 short paper on programming was published in English the same year,[49] and the preliminary report on the international algebraic language[50] was noticed in the Soviet bloc as well. Although both are known especially for their contributions to computing, Andrei Petrovich Ershov was trained as a mathematician and the editor of *Communications of ACM,* Alan Perlis, obtained a Ph.D. in mathematics from MIT. Both Perlis and Ershov are known for their involvement in the development of programming languages ALGOL 60 and ALPHA, respectively.

Conclusion

ALGOL 60 was embraced by researchers in Czechoslovakia and work on a compiler was reported, again in the *Communications of the ACM* in 1963.[51] Beyond that, ALGOL 60 also raised theoretical questions, and as such was approached by mathematicians.[52] In the 1960s, two of them, Jiří Kopřiva and Jiří Hořejš (1933-2001)[53] organised a series of seminars on the theory and practice of programming. This seminar gradually developed into a regular school in computer science, starting in 1974 under the name SOFSEM (short for SOFtware SEMinar). The Dutch programmer Edsger Wybe Dijkstra was a hero of this group, and quite officially so. Thus, the embedding of computer programming in mathematical environment contributed to the spread of the ideas about programming across political and economical boundaries.

MEDICINE IN THE 20TH CENTURY

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 1148.

SCIENCE, INDUSTRY AND IDEOLOGY IN 20TH-CENTURY CATALONIA: THE LEGITIMATING STRATEGIES FOR THE INSTITUT RAVETLLAT-PLA'S THEORY AND PRODUCTS IN LATIN AMERICA BETWEEN 1919 AND 1939

Sara LUGO MÁRQUEZ
History of Medicine Unit, Faculty of Medicine, Universitat Autònoma de Barcelona SPAIN
saritalugo@gmail.com

Abstract

Besides the controversy in Spain about Jaume Ferran i Clua's Anti-alfa vaccine and Calmette and Guerin's BCG during the first third of the 20th century, the veterinary Joaquin Ravetllat i Estech developed in Catalonia an alternative theory on the tuberculosis etiological variability. His ideas, together with the scientific and economic support of the physician Ramon Pla i Armengol, became fundamentals not only for founding the new Institut Ravetllat-Pla, but also for the fabrication and commercialization of two anti-tuberculosis products: the Suero Ravetllat-Pla and the Hemo-antitoxine Ravetllat-Pla. European hegemonic science was, however, committed to the mono-causality of Koch's bacillus. Therefore, Ramon Pla i Armengol was forced to expand his market to Latin America, generating a wide scientific and commercial network in approximately twenty countries from Latin America and Europe, including Portugal and Belgium. Through local commercial agents, the Institute not only distributed its products, but also spread its scientific ideas in scientific publications, including the journal published and edited by the Institute and entitled La Clínica *(1924-1936).*

The Institut Ravetllat-Pla became a corporation with a strong international projection, mostly thanks to the constitution and consolidation of a solid scientific and commercial network. This favoured the sale of their products, which embedded Pla i Armengol's scientific and ideological principles, and the survival of the Institute until 1980. Such a network model became crucial for exchanging ideas and constructing and developing knowledge. This case study will contribute to better understand historically how industries constituted an important mechanism for scientific legitimacy. Moreover, it will provide evidence of how both market economy and the legal and political definition of consumer products, specific from each country, are significant aspects in the making of science.

The Institut Ravetllat-Pla was founded in 1924. Its main activity was the study of the tuberculosis bacillus etiopathology and also the manufacture of two anti-tuberculosis products (the Ravetllat-Pla Serum and Hemo-antitoxin). The Institute maintained its activity until 1980, surviving four different political regimes while commercializing just these two pharmaceutical products. Interestingly, they were both based upon a scientific theory that was not and has not yet been approved by the official medical institutions. This Institute became a private company when their owners tried to donate the patent to the savings bank "La Caixa", which refused this request arguing that the ideas of the Institute "were not accepted in Paris, London, or Berlin" and therefore they could not be taken seriously[1]. The aim of my research is to determine which were the legitimating strategies that allowed the Institute to successfully spread its theory and products, and at the same time to obtain the approval of many physicians who praised the efficacy of this products in the tuberculosis treatment.

The founder of the Institut Ravetllat-Pla, Ramon Pla i Armengol (1880-1956), was a specialist in tuberculosis (phthisiologist), who never neglected his ideological values. He was a physician of the Catalonian Foundation against Tuberculosis (*Patronato de Cataluña para la lucha contra la tuberculosis)* and the Hospital de la Santa Creu of Barcelona, the founder of the Physicians' Union of Catalonia (*Sindicat de Metges de Catalunya),* and director of the journal *Annals de l'Acadèmia i Laboratori de Ciènces Mèdiques de Catalunya*. He was an active socialist, a member of the Catalanist Union and the Catalonian Federation of the Spanish Socialist Worker's Party, while he was lastly elected for the Catalonian parliament in 1936 as a member of the Socialist Union of Catalonia. Finally, in the wake of the Spanish Civil War, he went into exile, ending in Mexico, only to return to Barcelona in 1948. He died detached from the medical and political circles in his Institute in 1958[2].

Beyond the question about the efficacy of these pharmaceutical products, which by no means is clear so far, I want to propose that "healing success" is a relative concept, which depends on the particular context where it is defined. Thus, to begin with, I am focusing on some specifically historical questions: How do we define the "healing success" of any pharmaceutical product in the first half of the twentieth century? Which are the most important issues involved in a particular geo-historical context: consumers and sales rates; the number of physicians that prescribed the product; or the number of published articles to prove a given scientific theory?

Before the discovery of antibiotics, there was no treatment capable to completely eliminate the tuberculosis bacteria from the patients, notwithstanding people's living conditions in the period. Neither the serum from animals infected with tuberculosis, nor the tuberculin, nor the pneumothorax procedure, nor even the French BCG vaccine, were able to do away with the bacillus. Physicians searched for preventive therapies and ways to help the body to heal itself, but these as best managed to control the spread of the disease[3]. So, the relevant historical question is not if these products did actually cure, but: who and what defined the "healing success" of a given pharmaceutical product in a context where everything somehow worked but did not live up to expectations? And how and why were these products sold until 1980?

After the discovery of *Mycobacterium tuberculosis* by Robert Koch in 1882, the etiology of the disease was established. It was a simple and reductionist approach: one infectious agent, one disease, and one cure[4]. However, the difficulty to produce a specific and safe vaccine, the clinical variability of the disease, and the inability to visualize the bacillus in tubercles and infectious secretions, led to the emergence of new theories aiming at the bacillus variability. In this context, there came about the Ravetllat-Pla theory proposing that the tuberculosis bacterium was a changeable microbial species, with three different forms that are reversible among them, and each one producing a different clinical profile[5]. The new bacterial form discovered by Joaquim Ravetllat i Stech (1871-1923) and Ramon Pla was called "strike bacterium", which they considered the most virulent form of this bacillus. Indeed, the Institute research was focused on these bacteria, and the products developed were based on this form's capacity to trigger an immunological response.

Since the official scientific institutions did not recognize the Ravetllat-Pla theory, the Institute had to seek alternate legitimating strategies for the spreading of both the theory and their products. Some of these strategies were:

1. The creation of the Institute's own scientific journal.

2. Unrelenting scientific advertising campaigns, targeting specific publics: general and rural physicians and pediatricians.
3. Building a worldwide scientific-commercial network to promote the circulation of scientific knowledge, mainly about tuberculosis etiology.

An account of the most important features of these legitimating strategies follows. First, the journal *La Clínica. Revista Mensual Hispano-Americana de Ciencias Médicas* [The Clinic. Monthly Journal of Hispano-American Medical Sciences] was published between 1924 and 1936, and edited and sponsored by the Institut Ravetllat-Pla, while this was never stated in their pages. Four hundred and seventy-seven original articles about diverse medical topics were published in the journal; yet, the main subject-matter was tuberculosis, including research about the Ravetllat-Pla theory and products. In this context, the commercial success of the Ravetllat-Pla medicines did not just represent a lucrative activity, as Pla was saying, but also a legitimating keystone for the Ravetllat-Pla scientific theory. This legitimation required and indeed included the empirical proof of the efficacy of the products from many physicians, mostly general and rural physicians and pediatricians. These clinical studies were published in *La Clínica* and collected like comments to be shown in advertisements[6]. In this case, advertising was not only a persuasive technique toward potential customers, but also a way to spread and legitimate the scientific theory.

Fig. 1: Pamphlet example from 1952, showing the cities where the Ratvellat-Pla products were commercialized and tested. Chilean physician Miguel Farbes Yoaga's certificate declaring he tested the Ravetllat-Pla Serum in fifty children, with forty of them improving their physical condition, is reproduced.

One of the legitimating strategies that the Institute used for its consolidation was the creation of an extensive scientific a commercial network, mainly in Latin America. This network was built through commercial agents in each country, who distributed free samples and scientific publicity, issued free subscriptions to *La Clínica* for nearly all local physicians, and directly presented the Ravetllat-Pla theory in the official medical circles. This scientific-commercial network was used in the advertising of the Institute to strengthen its legitimization. Some advertising pamphlets showed the cities where the product was commercialized and tested, as well as places where the theory was discussed and the circulation of scientific

[6] Lugo, Sara (2010) "Entre ciència i publicitat. *La Clínica. Revista Mensual Hispano-americana de Ciencias Médicas* (1924 – 1936)". *Gimbernat* (in press).

knowledge actually took place. Additionally, also in the advertising of the Institute, physicians' certificates declaring their compliance and the success, proved by them, of the Ravetllat-Pla serums were used (figure 1).

Both, the scientific network and the journal allowed a wide scientific exchange between the Institute and the Latin American countries. For instance, the Institute discussed with a Cuban physician, Francisco José Velez (1885-1953) about "nuclear inversion", a phenomenon that takes place in the lymphocytes of tuberculosis patients, by publishing several articles about this topic in the journal. Velez had worked at important hospitals in Barcelona and Paris, had been the Local Health Chief Officer in Mariel (Cuba), and was at the time a phthisiologist at the Covadonga sanatorium in Havana. He was proposing nuclear inversion as a diagnosis method for tuberculosis[7]. Ten articles about Velez's theory were published in the Institute's journal. Among them, one study was made in Barcelona at the Ravetllat-Pla Institute, and later another one was Velez's response to the Institute's approach. Another example is Armando Pareja Coronel (1896-1965), Professor at the University of Guayaquil (Ecuador), and physician at the General Hospital, who researched about the Ravetllat-Pla theory and published his results in the journal[8]. He also presented this research in the Guayas Medical-Surgical Society on July 1925. One last example, illustrating specifically a pattern of scientific knowledge appropriation, comes with the Institute adopting a staining technique invented by Dionisio Cerqueira, a physician from Rio de Janeiro, who never showed any interest in the Ravetllat-Pla theory. This becomes clear in the letters between the Institute and its commercial agent in Brazil[9].

In 1935, Ramon Pla i Armengol made a trip across the Americas, visiting medical institutions and giving lectures in twelve countries. The local press used to inflate scientific events, in this case by publishing many articles announcing the arrival of "an eminent Spanish learned man". My initial assumption was that the relationship between Ramon Pla i Armengol and Latin America was built through official science channels[10]. However, although recognized Brazilian scientists actually received Ramon Pla, they did not really consider his scientific postulates, and because of this, Pla was forced to implement strategies different from those related with the official science, to legitimate the Institute's scientific theory. One of the strategies used by the Institute was to lure renowned scientists into trying and eventually compromising with its theory. For instance, since 1927, the Institute insisted on the importance of making contact with Antonio Cardoso Fontes (1879-1943), an important bacteriologist, who was the former director of the Oswaldo Cruz Institute, and who had a similar theory about the tuberculosis bacteria[11]. Ramon Pla i Armengol studied and quoted Cardoso's theories since 1925. Meanwhile, Fontes quoted the Ravetllat-Pla theory only once and in general terms. Cardoso Fontes held a cordial relation with the Institute. He actually welcomed Ramon Pla during his trip and showed him the laboratories where he worked, but this relation was not officially registered by the Oswaldo Cruz Institute. Indeed, Cardoso Fontes had publicly discredited the advance of the Ravetllat-Pla theory in Brazil. In 1928, upon the presentation at the Medical-Surgical Society of Rio de Janeiro of a research proving the Ravellat-Pla theory by Almeida Magalhães, who was a physician at the Army Policlinic and the Coscadura hospital, also a member of the League, and collaborator of the journal *La Clínica*, Fontes made the following comment, as told by Pla's commercial agent:

> "Having verified the reversibility of the bacillus as argued by you, Dr. Almeida Magalhães presented a paper at the Medical Society in the session held on the 16th of this month, receiving, as you will see, the response of Dr. Fontes, president of the Society, congratulating him for achieving higher happiness than him as, after twenty years of research on the subject, he had not been able to reach such result. Owing to the fact that I had to show Dr. Almeida Magalhães where Dr. Fontes' clinic was located, I happened to know for sure that [Dr. Fontes] had asked him for samples in order to make the experiments himself and thus verify the truthfulness of the proof."[12]

This was taking place when tuberculosis was not a priority for the Brazilian government, as it happened in the second decade of the twentieth century, even though it actually was one of the main causes of death. Indeed, the government public health measures were basically aimed at yellow fever, smallpox and bubonic plague[13]. In 1911 the "Brazilian League against Tuberculosis" –nearly the only organization dealing with this subject– abandoned its philanthropic and charitable discourse and adopted a more progressive approach, based upon scientific knowledge, and claimed for a governmental involvement in

[13] Nascimento, Dilene Raimundo (2005) *As pestes do século XX. Tuberculose e Aids no Brasil, uma história comparada*. Rio de Janeiro, Editora Fiocruz.

the fight against the white plague. The main objectives of the League were the establishment of new sanatoriums and to make hospitals take care of the isolation of tuberculosis patients[14]. In 1907, when the first sanatorium funded by the League started to work, the most used medicines were expectorants, antiseptics, astringents, local anaesthetics or restorative products[15]. These products did not contemplate, as a scientific basis, the immunological reaction produced by the tuberculosis bacteria. The Brazilian tuberculosis prophylaxis was influenced by the central medical discourse of the time as shown by the fact that the therapy against the tuberculosis was based in the use of the tuberculin, produced by the Manguinhos Institute and later on by the Oswaldo Cruz Institute, where Antonio Cardoso Fontes actually worked, and BCG, produced since 1918 by "the League" in the Viscondessa de Moraes Institute[16].

Another legitimating strategy for the theory implemented in Rio de Janeiro was to turn big international companies into permanent consumers of Ravetllat-Pla products. This is the case of the Canadian company, Light and Power, a huge worldwide emporium, which was significantly expanding in this period. This is the account from the Brazilian commercial agent:

> "[The Light and Power Company,] owner of phone lines, tramways, electricity, and buses in Rio, Sao Paulo, Bello Horizonte, etc., has declared the Ravetllat-Pla products as the official ones in its branch of its sort of welfare society section for its employees in Rio (only in Rio, it has approximately twelve thousand members with their corresponding families). They were doing experiments with [free] samples but they will start carrying them out with purchased products. They pretend to make a contract [to secure] monthly deliveries of a determined quantity."[17]

Nevertheless, Pla kept the scientific-medical focus of the advertising campaigns. Thus, for instance, in Chile, the sales campaign of the Ravetllat-Pla products failed because of the commercial agent's negligence, precisely because he did not want to use scientific channels for advertising. In the agent's words: "The publicity has to be done not in a scientific way, as it should apparently be, but rather in the Yankee way, as they are used to. So, you should not be surprised if you see some advertisements made in this way"[18].

To which Ramon Pla replied:

> "With scientific publicity occurs the same as with good coal, as it is hard to set alight yet once it has started to burn, it is the one that heats most and burns for a longer time. On the contrary, public advertising is like splinter fire, it burns quickly yet it goes out in a moment with no time to warm anything, while to maintain the heat you must constantly feed shavings."[19]

Ramon Pla changed this commercial agent, as his strategy, that is, the lack of scientific advertising, had an impact in product sales. In Pla's words to the new agent:

> "We note that you have activated the [scientific] publicity of our products, which we celebrate. It is really necessary to activate [scientific] publicity in Chile, since it is currently the country where we are getting the lower [sale] rates, despite the fact of being one of the first countries where the products were released."[20]

All these cases show that the Institut Ravetllat-Pla was a pioneer in the use of different strategies for scientific knowledge legitimation. Some of these strategies included: the creation of a scientific journal widely distributed, free for all physicians, in Latin America; medical publicity aimed at a specific public, such as general and rural physicians and pediatricians; the building of a huge transnational scientific and commercial network, which fostered knowledge circulation; and the involvement of big companies in the legitimating process. In all, the case of the Ravetllat-Pla serums illustrates that

patients consume pharmaceutical products as prescribed by physicians, even without consensual scientific approval, as shown by the Institute's successful legitimating and advertising strategies and, thus, high sales rates.

RECYCLING PSYCHOLOGICAL INSTRUMENTS

Sigrid LEYSSEN
Eikones NCCR Iconic Criticism, Basel, SWITZERLAND

sigrid.leyssen@unibas.ch

Abstract

When looking at a series of Albert Michotte's successive experiments on perception from the 1920s through the 1940s, it becomes clear that the instruments he used in these experiments were not fixed and stable entities. They were especially chosen and developed for being flexible and easy to adapt. Michotte's method required this easy access to the instruments in order to experiment on an extensive variety of related impressions. The instruments did not only constantly evolve within a certain series of experiments (e.g. the experiments on causality), but when a certain investigation was completed, Michotte often recycled parts of the instruments in order to create new instruments for a new experimental study. Many of the instruments, moreover, had already been borrowed from other laboratory or artistic practices, and had been adapted to the specific purposes of the experiment. The practices of adapting and recycling thus transcend the context of one psychologist or one laboratory. I will discuss these practices of adapting and recycling by looking at some concrete instruments used and developed by Michotte and his technician M.L. Roland.

This paper is about the role of *recycling* in the creation of new psychological instruments. I will look mainly at instruments of one particular psychological laboratory, situated in Leuven, Belgium, during the first half of the 20th century: that of the experimental psychologist Albert Michotte (1881-1965). Here the focus will be on instruments that were developed for showing visual stimuli to observers.

I start from the observation that new instruments often were developed by reusing, *recycling*, parts of older existing instruments, often those that were present in the laboratory. I consider as 'recycling', both the taking material parts out of older instruments in order to reuse them in a new one (which I call the *recycling of material elements*); and the reusing of certain design structures of known instruments in the new constellation of a new instrument (which I call the *recycling of structural elements, or design elements).* Both of which were common practice in the psychological laboratory.

These recycling practices can be seen as determining to a considerable extent what new instruments would be like. A new research topic often asked for a new experimental set-up, and new instruments had to be constructed. Yet this new topic was often embarked upon with instruments built up from parts of instruments available in the laboratory or as an assemblage of certain structures of already familiar instruments.

This also means that this practice of recycling determined to a considerable extent the kind of stimuli that were presented to the observers in the experiments. The new stimuli necessary for the new investigations were already largely determined by the corpus of existing instruments.

In this paper, I retrace certain paths of recycling, as a way to better understand specific instruments and to grasp why they were built the way they were. My main aim with this approach is to shed light on how a certain tradition of presenting visual stimuli was created in experimental psychology.

Recycling material elements

For the case of the recycling of material elements, the optical element of Michotte's tachistoscope provides a telling example. Tachistoscopes, most often used as short exposure devices, had been in use for about half a century in different versions in physiology and experimental psychology (Benschop 1998) when at the international Congress of Psychology in 1909 in Genève, Albert Michotte, then a young professor in experimental psychology, presented his own version of the tachistoscope (Claparède 1910; Michotte 1912, image: http://vlp.mpiwg-berlin.mpg.de/vlpimages/images/img24638.jpg). What was new about this tachistoscope with its two large rotating discs, was that two different images could be shown simultaneously or successively, in short, variable and precisely determinable intervals, and, due to a special optical element, presented at the same spot on the retina. Michotte describes many possible uses for the instrument: next to the usual tachistoscopic experiments, it could also be used for research on immediate memory, stroboscopic illusions, or consecutive images. It also could make experimental setups for research on simultaneous associations (Narciss Ach) or extensions of consciousness (Wilhelm Wirth) much simpler.

Michotte's *comparison tachistoscope*, as the instrument was called, has not been preserved. It must have been subject to some pride, as it was one of his first instruments taken into production by one of the most prominent psychological instrument makers, Ernst Zimmerman (Zimmerman 1912), yet it was dismantled. Its optical element, however, has been preserved. It consisted of a combination of prisms, some with silvered sides, so that the light rays of the objects (images on paper cards placed in cardholders on either side of the discs) are broken in such a way that they end up on the same spot of the retina. This optical element, which was the most expensive and original part of Michotte's comparison tachistoscope, was then reused in another kind of tachistoscope, a fall tachistoscope, which has been preserved. (image: http://www.erfgoedplus.be, KULppw030).

Original instrument parts travelled in the laboratory from one instrument to the other. We got to known this particular optical element as part of the last instrument in which it was used. Due to the fact that this optical element was clearly described as part of an earlier instrument, and had been presented and published as such, it can be traced back to its original place.

Recycling structural elements

Next to the recycling of concrete, materially available instrument parts for use in a new instrument, I want to look at the practice of reusing certain *design elements* from known instruments. This, I argue, is another, often recurring practice of recycling, looking at which allows to relate different instruments to one another and helps us to gain a better understanding why certain instruments were designed the way they were.

It is striking, for example, to see the recurrence of rotating discs in physiological and psychological instruments. Another recurrent structure is that of a narrow slit or window (of different forms and sizes) in a covering screen which uncovers, partially or temporarily, an object behind it. The instruments I discuss here all combined rotating discs with such slits. The combination of these two design elements, however, could take many different variations.

In Michotte's comparison tachistoscope, there were two black metal rotating discs, each 90cm in diameter, and both carrying a slit whose size was adjustable. In Michotte's laboratory, another such black metal disc with an adjustable slit could be found, although in a smaller format (40 cm in diameter), in a tachistoscope in a design of Friedrich Schumann (Image, see http://www.uclouvain.be/235628.html) which has been preserved as well. This was another and smaller version of the tachistoscope Schumann presented in 1904 at the 'Ausstellung von experimental-psychologischen Apparaten und Methoden', accompanying the first 'Kongress für experimentelle Psychologie' in Giessen.

Such rotating discs were not part of the first tachistoscopes, where rather, as e.g. in Alfred Volkmann's tachistoscope (Volkmann 1859), the slit was in a thin metal plate, which was pulled by a falling weight over an underlying image, revealing it briefly (Image: Benschop 1998, p.28). Rotating discs became part of tachistoscope designs when recurrent, periodical stimuli became important for certain research topics.

The use of rotating discs in tachistoscopic designs, in its turn, made the instrument susceptible to yet other tasks in other experiments. Max Wertheimer used an adapted version of Schumann's tachistoscope in his famous studies on seeing movement in 1910 (Wertheimer 1912). These experiments illustrated how rotation tachistoscopes could be used in experiments on movement perception, allowing to study what had been investigated with stroboscopes with now much more precision. Michotte also explicitly mentions that his comparison tachistoscope can be used especially for stroboscopic movement studies.

When three decades later, in his experiments on the perception of causality (Michotte 1941; 1946), Michotte needed not simply moving stimuli, but what he called 'dynamic' stimuli, he took recourse to these same structural elements of rotating disc and slit again. He needed a way to present moving objects in different kinds of interactions, and this in such a way that the parameters of these stimuli could be easily varied and precisely controlled. These new dynamic stimuli were created by constructing a new instrument, the *Banc Michotte* (image: *http://www.uclouvain.be/235664.html*), which was hailed by his colleagues for its inventiveness. This new instrument however was also an assemblage of many different structures already available in familiar instruments in new combination.

Michotte developed the Banc Michotte together with his technician Léon Roland. Large paper discs (50cm in diameter) with lines in different colours painted on them were rotated behind a big white screen. In the screen was a small horizontal slit. Observers had to sit at 1.5 meter from the screen, focus on the middle of the slit, and report what they saw. They described that they saw, for example, a red rectangle bumping into a black one and setting it in motion. With these abstract moving images Michotte studied the perception of interactions between objects, causal interaction in this case, as something that is directly given in perception.

The Banc Michotte could perhaps be seen as one of the last versions of the tachistoscope or short exposure apparatus before the computer largely took over as a stimuli presentation apparatus. It was, however, a version of the tachistoscope which was adapted to the presentation of moving interacting figures. It took over the elements of rotating disc, the slit and the shortly uncovering of an underlying image. In addition to this, it also included design elements from other familiar instruments, combining all these in a new constellation. Let me trace in a sketchy way some of these structural elements and their combinations.

1. In the Banc Michotte, in contrast to the comparison tachistoscope, it is the discs themselves which are the image carriers. They carry coloured lines in many different combinations. Rotating discs carrying inscriptions already had a long history in perception research. In colour research, discs with segments in different colours painted on them are mounted on different kinds of rotating devices (e.g. the colour mixer by Goethe & Otto Runge). Such colour discs and different kinds of rotating devices were present in most psychological laboratories of the time, and also Michotte's laboratory in Louvain possessed different of these rotating devices. Rotating discs with different areas painted black or white were also used in research on contrast perception (e.g. Ernst Mach 1865). Very well-known were also those discs with figures in different stages of movement, used for studying the perception of movement, such as the 'phenakistoscope' of Joseph Plateau (Plateau 1832).

2. The inscriptions on the discs are not discrete figures, or coloured segments, but continuous lines. In this respect they resemble perhaps more Plateau's famous spiral disc, with which he showed the 'spiral motion after-effect'. To make the relation with another domain of knowledge where vision was investigated, they do remind strongly of some of Marcel Duchamp's rotoreliefs (1935) as well. The lines on Michotte's discs however are no spirals or eccentric circles, but arcs of a circle, mostly in red and black, drawn with much precision in such a way that, when looked at through the slit, they could present exactly those stimuli to observers necessary for them to see one figure setting another in movement.

3. Crucial in the Banc Michotte was that the rotating discs had to be looked at through a slit. Whereas the colour and contrasts discs had to be looked at as a whole, Plateau's discs also were looked at through various slits. Whereas these slits, however, were plural and located in the disc itself, thus rotating as well, in the Banc Michotte, there was only one slit which was located in a large fixed covering screen. In contrast to most models of the tachistoscope, where a fix image is briefly revealed by a (circularly or linearly) travelling slit, here it is the images that travel, and the slit is fixed. Yet there is a similar structure to be found in that both are briefly uncovering an underlying image. Whereas in the tachistoscope the view on the whole image is shortly revealed and then cut off again, the working principle of the banc Michotte is that only part of the underlying image is revealed at each moment. It was the task of the slit to cut out a small portion of the total view, and it is only then that the intended images in the moving displays are created.

Some elements of the rotation tachistoscope were combined here with the principle of a then popular illusion: that of pulling a strip of paper with a diagonal line on it, behind a little screen with a horizontal slit. In the slit one sees a figure moving from left to right. The construction of motorized rotating discs, put in continuous movement, and the many hundreds of discs with different line combinations allowed to employ this illusion for the study of causal impressions, in a way that was flexible, variable and controllable.

With this tracing of instrument structures, I wanted to argue that, when looking at stimulus presentation instruments in experimental psychology, from the beginning of scientific psychology until about the 1960s, their seems to have been *a pool of design elements*, a corpus of structures, which were recombined and reassembled in many different combinations. The Banc Michotte is a late and complex instance of this 'recycling' tradition.

In this pool of design elements, moreover, it seemed that *some elements obtained an exemplary status*. Some became as it were *standard design elements*. I would like to argue that the rotating disc and the slit were two such important, often recurring elements. They were used again and again, in instruments of various kinds with various functions. Combined together, rotating discs with slits in them even received a specialist name, being called the Episkotister principle. But rotating discs and slits kept on recurring in many different combinations. This frequent recurrence no doubt had to do with their usefulness for various ends; and with their material presence in almost each psychological laboratory. This made that they became elements that were readily available to the *technical imagination*. For those who had to construct new instruments for newly needed presentation tasks, rotating discs and covering/uncovering slits were some of the forms or structures that came easily to mind. They were 'recycled' time and again, extracted from instruments that were not of any direct use for the envisaged experiments, and fitted into new instruments to tackle the next problem.

Recycling stimuli

I have argued how recycling was often an important factor for what new instruments would be like. This common practice of recycling instrument parts and design elements in order to construct new instruments, moreover, also determined to a considerable extent the *kind of stimuli* that were created to show at the observers. Looking at these recycling practices can help to explain how, step by step, *a particular way of showing stimuli* and also *a specific kind of stimuli* became accepted in psychology for use in perception experiments.

Nicolas Wade, in his book *Perception and Illusion* (2005), shortly addresses the question of how it became accepted in experimental psychology to use images instead of substantial objects and real life scenes as stimuli for visual perception research. As one of the explaining factors, Wade points to the import of Charles Wheatstone's work, showing that the perception of three-dimensional space can be synthesised from two dimensional stimuli. Wade argues how the acceptance of pictures for the study of vision was important to the development of psychology as an independent experimental science because it allowed to confine the research to the laboratory, and to allow for variation, control, and exactitude (Wade 2005, p126-127). My approach of looking at recycling practices presents a way to understand why *particular* kinds of images came to be used so frequently in vision experiments.

Through the recycling of instrument parts and structures, often also a *recycling of stimuli* took place. Michotte's bumping figures used in his causality research worked in a sense as surprisingly new. These apparently simple, yet very precise moving displays, with small coloured rectangles in many movement variations drawn on white paper and seen in a corridor formed by the slit, were in a new sense, yet these stimuli and the way they were framed also strongly referred to a large number of stimuli presentations from previous experiments. The schematic images, the geometrical forms, the colour palette, their precision, the corridor formed by the slit in which they were presented: many of these aspects were explicitly chosen and argued for, sometimes also supported with experiments, as aspects which could enable or advance the experiments. Yet they also referred back to many psychological images used before them.

Tracing more in depth this recycling of stimuli would need another paper. What I wanted to argue within this paper was how looking at recycling practices can offer a promising route to better understand certain instruments and the stimuli images used in them. It will need to be further explored how the recycling of material and structural elements of stimulus presentation instruments has contributed to the creation of what could be called a *stimulus canon* in perceptual psychology.

FILM, MEDICINE AND EMPIRE: INCLUSION-EXCLUSION PRACTICES AND DISCOURSES IN SPANISH MEDICAL-COLONIAL DOCUMENTARIES OF THE 1940S

Carlos TABERNERO[1], Isabel JIMÉNEZ-LUCENA[2], Jorge MOLERO-MESA[1]

Abstract

Inclusion-exclusion dynamics in contemporary societies are complex, multidimensional processes involving the active intertwining of wide-ranging social, economic, political and cultural factors.
In this regard, scientific-technological discourses, considered as a basic constituent of western hegemonic thought, play a fundamental role in the definition, classification, framing, rationalization and disciplining of distinct human clusters. This is especially apparent when conveyed through health-medical practices and policies, inasmuch as direct contact between experts (physicians) and laypeople (patients) necessarily occurs through practice itself, which in turn purportedly offers immediate solutions to pressing everyday life problems. On the other hand, mass media, particularly when image-based, such as in the case of film or television, are crucially conducive of the construction, diffusion, representation, interpretation and reinterpretation of the beliefs and values upon which human communities are shaped. Moreover, they are also technological means of contact between experts (writers, directors, producers, distributors) and laypeople (readers, listeners, viewers), offering as well multifaceted immediate solutions (information, entertainment) to modern life needs, and thus bearing an undeniable strategic importance precisely from a joint social, economic, political and cultural point of view.
Upon these premises, our aim is to contribute to the historical understanding of the role played by the concurrence of the cinematographic and scientific-medical discourses in inclusion-exclusion dynamics in the context of post-war Spain. To do so, we have analyzed from this perspective five medical-colonial documentaries produced between 1946 and 1949, three of them in fact under the directive of Franco's government. In these films, a third discourse (colonial), equally strategic for the regime, plays an essential and

complementary role as well. Thus, the joint articulation of these three discourses offers some explanatory keys for basic inclusion-exclusion traits pertaining to the categories of gender, class and ethnic group.

The aim of this paper is to contribute to the historical understanding of the role played by the concurrence of the cinematographic and scientific-medical practices and discourses in the construction, legitimating and consolidation of Franco's regime. Through the analysis of the representation and articulation of health-medical practices and discourses in post-war Spain's medical-colonial documentary films, this study offers some explanatory keys regarding the multidimensional relations between different collectives (experts and non-experts) concerning the nature and degree of intervention in processes of generation and management of scientific-medical-health knowledge, all within the particular case of the creation of a 20th-century totalitarian regime. The addition in these films of a third set of practices and discourses, i.e. colonial, equally strategic for the regime, allows to explore the processes of science, medicine and technology popularization involved in relation to inclusion-exclusion dynamics, insofar as the explicit classification, rationalization and disciplining of distinct human clusters (race, particularly in this case, yet along with class and gender) was an essential feature in the construction of the new national identity.

Indoctrination needs in post-war autarchic Spain (1940s)

At the end of the Spanish Civil War (1936-1939), Franco and his backers faced the challenge of establishing and consolidating a new regime. The task was to (re)build the social, economic and administrative structure required for survival in a territory immersed in chaos after three years of war devastation. This, logically, had to be achieved under the provisions of the regime's political, ideological and cultural legitimating needs at home and abroad, all within a context of intense power struggle between the different political, social, economic and ideological families aiming to enter the ruling layers. Such complex process led to an autarchic articulation of the regime owing to the combination of at least three key factors: first, the paternalistic structuring of the system, where survival (of the regime, i.e., of the people) was forcibly identified with the *Caudillo*'s, whose personal authority became the axis of the political, ideological and social strategy of the regime; second, the building and establishment of the new order through the rooting out of all vestige from the Republican period, including, as expected, the subjugation of any trace of dissidence; and third, the increasing isolation of the regime in the international arena as the European friend regimes in Germany and Italy were being defeated in World War II, coupled with Franco's regime non-belligerent position according to the priority of survival needs over ideological considerations[1].

Under these circumstances, a multidimensional, strong-arm policy was required for the combined exercise of building, consolidating and legitimating the regime. In this process, an efficient indoctrination of the population was a key feature and needed the articulation of a discourse leading simultaneously, on the one hand, to the justification of a paternalistic, i.e. repressive *and* benefactor, as well as unwavering and enduring system; and, on the other, to the expedient social and historical de-contextualization of the situation, so that a new national identity would be created[2]. This was achieved, among other aspects, upon the construction of a political project, the national-syndicalism, which involved the structuring of knowledge management in a strict vertical flow of information, *from one* (the One, Franco) *or a few* (the Fascist Party, the military, the Catholic Church) *to the many* (the population at large), where adherence to the rulers, in political, ideological and moral terms, was as important as subjection and obedience to the experts, in practical terms[3].

About practices and discourses: film, medicine and empire

Among the different indoctrination devices available to the regime, the use of two sets of practices and discourses, medical-health and mass media, otherwise essential for the construction and management of contemporary societies, was particularly suitable. Medical-health practices and discourses develop around the concepts of health and disease, upon which complex social dynamics are structured, from the building of wide-ranging health systems and policies, to the multifaceted dealings, at the personal level, between physicians and patients. On the other hand, mass media practices and discourses are crucially conducive of the construction, diffusion, representation, interpretation and reinterpretation of the beliefs, values, concerns and expectations upon which human communities are shaped.

1 Monterde (2004); Tabernero (2008).

2 Medina-Doménech and Menéndez-Navarro (2005); Tabernero (2010).

3 Tabernero (2008, 2010).

Both medical-health and mass media practices and discourses revolve around knowledge circulation and management between experts (physicians, scientists, professors/teachers; writers, directors, producers, distributors; policy-makers, companies, institutions) and non-experts (the population at large; patients, students; readers, listeners, viewers; users, customers), thus bearing an undeniable strategic importance from a joint social, economic, political and cultural point of view. It is no surprise that Franco's regime regarded them both as primary means for the building of its social and political scaffolding, and insofar as indoctrination was a key feature in this process, the approach, as it would eventually be for any developing totalitarian system, albeit not exclusively, was that of an unconcealed diffusionist model of knowledge management. According to this model, the dynamics of socio-cultural construction and organization would be based upon unidirectional and asymmetrical flows of knowledge generation, transmission and circulation, where the few experts are the creators and managers of knowledge, and the many non-experts are purportedly passive, non-participant, submissive and dependent receivers of that knowledge and its consequences in the contexts of their everyday lives. Therefore, the (medical-health and media) experts would be *the* necessary source of immediate solutions (in this case, health, information, education, entertainment) for the non-experts' pressing everyday life problems (disease) and needs (the articulation of the symbolic framework and the time and space organization upon which social life develops)[4].

As a result, on the one hand, medical-health discourses and practices were used to address immediate needs in post-war Spain, such as widespread poverty, starvation and epidemics, mainly through the establishment of a public health system which, at the same time, and given their fundamental scientific-technological trait, that is, allegedly neutral, could define and control social clusters as well as their values and behaviour, thus contributing to the building and legitimating of the regime[5]. On the other, mass media were deemed as essential means of enculturation, through the combined functions of information, education and entertainment, by way of generating apt representations of the regime. Besides the press and the radio, cinema, as "the most popular form of entertainment in Spain in the post-war years", was fundamental to provide the Spanish population with new socio-cultural meanings, including those related to science, medicine and technology[6]. Moreover, documentary films, that is, the most scientific-technological form of cinema as provider of theoretically faithful, objective reproductions of reality, would be particularly apposite to enhance the most diffusionist approach of knowledge management. As it was stated,

> "It has become essential to develop a body of documentaries, in the service of our propaganda agencies, able *to reflect in an exact, artistic manner, and through a perfect technique*, the different aspects of our Fatherland's life, and, *in the most entertaining and efficient way, to educate and instruct our people*, to persuade those still possibly mistaken of their error, and to show foreigners the wonders of Spain, the progress of our industry, our natural resources, *the discoveries of our science* and, in all, the resurgence of our Fatherland in all its aspects as impelled by the new State".[7]

Indeed, along these lines, medical-health content was used in the compulsory and exclusive official newsreel of the regime (*NO-DO*) as a valuable legitimating tool and a key feature for the building of the new national identity[8].

Finally, the documentary films analyzed in this study incorporate a third set of practices and discourses, the colonial-imperial, which was equally strategic for the regime, and plays and essential and complementary role. The aims were unequivocal, as were the functions of science and medicine in the post-war context of Spain and the legitimating significance of their portrayal for the regime, both at home and abroad:

> "All countries with colonial expansion took one and many times to the screens of the world the account of their realities or perhaps their fantasies in the territories distant from the mother country. In this sphere, there is only missing the sweet melody, all indisputable truth, of the most noble heroic deed of those great Spaniards –missionaries, officials, teachers, *men of science*– who proclaimed and proclaim in the lands of Africa the religion of Christ, *the conquests of medicine*, the essences of culture, that a man needs to live his time […] this task well deserves to be broadcasted in the screens, as the screens already broadcasted the war heroism that made it possible".[9]

The documentary films by Manuel Hernández Sanjuán and Santos Núñez

Five medical-colonial documentary films have been analyzed in this study. All of them were produced by Hermic Films. *Médicos coloniales* (*Colonial physicians*), *Los enfermos de Mikomeseng* (*The sick people from Mikomeseng*) and *Fiebre amarilla* (*Yellow fever*)[10] were directed by Manuel Hernández Sanjuán (1915-2007), co-founder of the production company, in Equatorial Guinea in 1946. They were part of a governmental request made directly to Hernández Sanjuán by the General Director of Morocco and Colonies, General José Díaz de Villegas Bustamante, to make "documentaries about the Guinean colony, with the aim of showing to Spain the job that was being done"[11]. The result was the production of 31 documentaries (the Equatorial Guinea series) classified under seven thematic clusters: 'Woodland resources', 'Ethnology of inhabitants', 'Wildlife and natural phenomena', 'The work of missionaries and education', 'Development and technology', 'Military exaltation' and, significantly for this study, 'Tropical diseases and health', to which the three documentaries mentioned above belonged.

In spite of the governmental sponsorship, these documentaries were poorly distributed. The official premiere was held on May 22, 1946, at 7 p.m., in the Music Palace Theater in Madrid, where General Díaz de Villegas was in attendance. Later on, there were some sporadic open showings in Spain (1947) and Guinea (1948), as well as some private showings for officials in Guinea and Tetuan (1948). Some fragments were subsequently used as inserts in other films, including fiction[12].

The other two documentaries, *Enfermos en Ben-Karrich* (*Sick people at Ben-Karrich*) and *Médicos en Marruecos* (*Physicians in Morocco*)[13] were directed by Santos Núñez[14], who had been the scriptwriter of Hernández Sanjuán's Guinea documentaries, in Morocco in 1949. They are a product of the long linkage of Hermic Films with colonial cinematographic projects made in both Guinea and Morocco[15]. Núñez's documentaries, as well as Hernández Sanjuán's, were made to fit the format of *Revista Imágenes*, which was one of the forms of the regime's official newsreel (*NO-DO*), although they were not ultimately shown as such.

The documentaries made in Guinea met with critical acclaim. Ignacio Mateo, National Radio commentator during the official premiere

> "praised the importance of cinema when applied to a cultural and patriotic venture, as it is *to reflect and broadcast* Spain's *fruitful civilizing effort* in those African lands, according to its tradition".[16]

This unmistakably shows the regime's interest in film as a wide-ranging ("broadcast") and objective ("reflect") educational tool. Similarly, the official press took the chance to explicitly insist on the objective character of documentaries as opposed to fiction films:

> "Accustomed, in the easy entertainment before the screen, to those sophisticated jungles made in Hollywood studios, we are impressed by *the realism of those naked and truthful images,* devoid of shady, laboratory-made tricks"[17].

These documentaries efficiently complied with their triple enculturation function: first, the films provided information, as they documented a distant reality, from the mother country's point of view; second, they were a source of education, as we have seen concerning the colonial venture and its civilizing (social, cultural, ideological, organizational) implications, but concurrently, given the thematic focus, in relation to health policies and the associated practices and behaviors; and third, they offered entertainment, inasmuch as the distant and somehow problematic context featured was portrayed as 'exotic' and 'heroic'.

Indeed, medical-health practices and discourses are represented and articulated in these documentaries as a necessary and heroic, as well as, owing to its scientific-technological character, mostly a practical and impartial source of construction and organization of a specific kind of societies, that is, the colonies as administered by Franco's regime. In this regard, it is significant that medical-health issues as well as science and technology (resources, ethnology and wildlife) were crucial thematic axis, as shown by the focus of the seven series of the Guinean film project, along with religion, education and the military. Thus, regarding the enculturation effort, and through the combined functions of information, education and

entertainment, these documentaries not only highlight the weight of medical-health practices and discourses as building and managing tools for the regime, but also, through the combination with the scientific-technological character of documentary filmmaking, that is, of the form simultaneously with the content, they become an overt legitimating (educational, as seemingly impartial) device.

Film, medical-health and colonial practices and discourses: inclusion-exclusion dynamics in 1940s' Spain

If the scientific-technological factor of medical-health and documentary film practices and discourses is used as a source to convey certainty, cohesion and power, the colonial-imperial venture provides an explicit representation of the associated, expert-driven and, as such, purportedly impartial processes of definition, classification, framing, rationalization and disciplining of distinct human clusters. This allows exploring the processes of science, medicine and technology popularization involved particularly from the perspective of inclusion-exclusion dynamics[18], i.e. power relations as related to medicalization processes and their impact in the social, political and cultural construction of the new national identity in post-war Spain. Such an analysis is also possible insofar as the consideration of medicine, film and empire as sets of 'practices and discourses' implies an acknowledgement of their embedding in multidimensional forms of everyday social action and interaction between individuals, groups and institutions[19]. With this premise, the analysis focuses on the (medical-health and colonial) discourses articulated in the films, the related representations of the spaces and instruments employed, as well as of the (expert and non-expert) people who inhabit and use them. As a result, an account of the interrelated position of all the actors involved with respect to the regime's aims and needs is suggested, from all the people (experts and non-experts, colonizers and colonized) featured in the documentaries, to the intended audiences (mostly in the mother country) and the filmmakers themselves.

The voice-over narration kept the "voice of the One" quality featured in the pieces produced and/or dubbed for the compulsory and exclusive official newsreel (*NO-DO*). Under the primary informational disguise, the aim was ultimately the glorification (i.e. legitimating) of the regime, conveniently de-contextualized from the joint social and historical points of view. In addition, the language used, far from actually provide with valuable information and/or educational content about specifically medical-health issues, efficiently combined technical expressions concerning diseases (etiology, prevention, treatment), the consequent application of expertise and technologies, and the associated, albeit far-reaching, health policies, with colloquial phrases, from the completely informal regard precisely of diseases, technologies and policies as well, to the insertion of anecdotes ultimately enhancing the entertainment side of the films. Taken together, all these elements conveyed an apparently truthful definition of an authority whose character was outwardly expert, practical and unbiased, but also, simultaneously (along with the inescapable religious and military elements), severe, unwavering and familiarly paternalistic ("we are all under the One")[20].

The representation of medical technologies and facilities provided with the required sense of (yet again, fittingly de-contextualized) "order, strength and cleanliness" associated to the New State. However, as opposed to the static objects and empty spaces usually displayed in the official newsreel through the 1940s, these documentaries showed instruments being truly operated by physicians and technicians as well as facilities (hospitals and clinics) swarming with patients. "The ideals of modernization and efficacy [were indeed] symbolized through technical display"[21], yet the actual application of these technologies and facilities in the colonial context, as portrayed in the screen, conveyed a powerful sense of the competence and dependability, i.e. legitimating, of the regime as a genuine provider of imperative solutions, despite the difficulties associated to its international isolation[22].

Finally, the depiction of the social dynamics taking place in these crowded facilities featured a clear-cut differentiation between medical-health experts and non-experts, and thus an essentially practical classification, rationalization and disciplining of distinct human clusters across race, class and gender. According to the diffusionist model applied, as aforementioned, the experts (officials and physicians; all of them Spanish –white– men) rigorously and efficiently provided immediate solutions to pressing everyday problems afflicting the non-experts (patients, or the population in danger: natives, in this case men, women and children, explicitly from working-class and peasant families; and Spanish women and children, particularly in the Moroccan context). The only, albeit partial, exception to this scheme is the possibility for natives and

women to become medical-health technicians, that is, one step closer to the expert dominion, yet still as subaltern staff always and necessarily under the close supervision of the specialists, in a sort of otherwise unambiguous 'excluding inclusion'[23]. It is noteworthy, from the point of view of the regime's needs concerning the construction and consolidation of the new order, that the non-experts' intervention is always openly portrayed as captive and submissive, where compliance with the experts' supposedly objective and unbiased medical directives and, by extension, moral and ideological principles (as constantly suggested in the screen by the religious tutelage, mostly represented by nuns), becomes, sometimes, disturbingly docile[24].

Conclusion: colonizers and the colonized

Upon these features, while the informative/educational purpose regarding the civilizing endeavour of the Spaniards is inescapable for potential native viewers, a two-sided identification effect can be argued concerning the intended Spanish –white, mostly at the mother country– audiences. On the one hand, the primary and straightforward identification would be with the colonizers, the ruling Spaniards. Yet, on the other, they could very well identify as well with the colonized, inasmuch as patients, workers, peasants, and particularly women, in deep need of solutions and information, specially pertaining to medical-health issues, but also with regard to the new regime's intentions and capabilities.

This succeeding identification pattern is achieved by the combination of a number of cinematic techniques displayed in the documentaries: first, the adoption of a distinctively didactic format, aptly combined with the entertainment trait mentioned above, through the use, as introduction or for contextualization, of animated graphics and maps, microphotography techniques, and illustrated historical accounts of the medical-health issues shown, always conveniently devised and structured according to the regime's essentialist aims and asymmetrical information model; and second, the portrayal of medical-health science and technology as spectacle, as a set of commodities ready for everyday consumption, and made possible precisely through the (as explicitly qualified) self-denying, rigorous and outstanding efforts of the experts and officials, whose guiding and civilizing function thus becomes undeniable. In this sense, the filmmakers themselves play two different and complementary roles, as colonizers, for, upon arrival, they join the ruling communities both in Guinea and Morocco, but also as 'colonized', inasmuch as they are direct witnesses, and thus, the very first public, of the regime's colonial and related medical-health endeavours, for which they offer, in their films, a primary interpretation.

As a result, the documentaries themselves are part of the solution, as they offer not only information and education, but also evasion, so much needed in post-war Spain. The movie theatre thus becomes an entertainment-driven science space, where everyday communication practices are efficiently intertwined with, in this case, medical-health instruction, featuring essential social, political, moral and ideological aspects pertaining to the seemingly unbiased definition and disciplining of human clusters according to the regime's needs.

Abstract

Polyvinyl chloride (PVC), a polymer, is one of the most known and used plastics in the world. This plastic has worldwide applications in sectors such as construction, consumer goods and food packaging. In spite of usefulness of this material, in the early 1970s, complaints surfaced regarding potential links between a kind of liver cancer and vinyl chloride monomer (VCM), a small chemical unit that is used in synthesizing PVC.
This paper firstly analyses the health-history of VCM and PVC, and the outbreak of first the 'hand-disease' (acro-osteloysis) and then liver cancer (angiosarcoma); and secondly how chemists, the industry, the governments, the press, and public in general reacted to this event. We will analyse in a comparative manner the (different) responses in the USA and in Europe.

Polyvinyl chloride (PVC –Figure 1) is one of the most widely used plastics in the world. However, in the early 1970s, complaints surfaced regarding potential links between a kind of liver cancer and vinyl chloride monomer (VCM –Figure 2), a small chemical unit that is used in synthesizing PVC.

During the 1940s and 1950s several cases of occupational illness among PVC workers were described in the medical literature.[1] The causes of those illnesses remained obscure, though. Initially, it was frequently thought that the unhealthy effects were caused by the plasticizers that were added to the PVC. Later, there were growing indications that VCM might have some chronic toxic effects, especially on the liver, the kidneys and the skin. These indications were

confirmed in an experimental study on laboratory animals executed by researchers of Dow Chemical at the end of the 1950s. Dangers of VCM were not discussed, but the scientific results were published in a medical journal in 1961.

In the course of the 1960s a specific clinical syndrome was encountered with increasing frequency by general practitioners, specialists, and medical doctors associated with PVC factories. Some workers complained about severe pain in their fingers, which had become white pale, as in case of frost. Often bone changes, shortened finger limbs or clubbed fingers were diagnosed by the doctor. Serious cases of crippled workers that had to leave their jobs were reported as well. The syndrome got the name 'acroosteolysis.' After about 1965 it became increasingly clear that the illness was quite typical for workers in the PVC industry and for autoclave cleaners especially. At Tavaux, for instance, six cases of acroosteolysis were discovered between 1965 and 1970. But many uncertainties remained; there were numerous chemicals involved in PVC manufacture and workers were employed in many different positions. As a result, it lasted until 1971 before an extensive industrial hygiene and epidemiological research project, sponsored by the Manufacturing Chemists Association in the USA, irrefutably proved that acroosteolysis was caused by vinyl chloride and occurred almost exclusively among reactor cleaners in PVC plants. In the VCM plants proper the illness did not occur, because production there often took place in highly automated open air facilities, where no manual work was required. Preliminary findings of this large study were already presented in 1969 at a conference.[2]

VCM Incident –Its Carcinogenicity

At the 10th International Cancer Congress at Houston, Texas, in 1970 the Italian physician Pier Luigi Viola (1917-1985) gave a paper on the occurrence of cancer in rats that had been exposed to very high doses of vinyl chloride. This was the first public announcement of a link between VCM and cancer. It soon received attention and would get great consequences.[5] Viola was director of the Ospedale Aziendale, founded by Solvay, at Rosignano and connected as medical doctor to the local Solvay plant. In order to study the relation between VCM inhalation and acroosteolysis he had started in the late 1960s an experimental study on rats in the cellars of the hospital. During those studies he found that the rats developed cancers in several parts of their bodies. Immediately after the presentation of his results Viola was contacted by Professor Cesare Maltoni of Bologna University, who was involved in an extensive study on the effects of chemicals on the respiratory tracts of Italian workers. He received from Viola a manuscript of a report on 'The Vinyl Chloride Disease,' that he had written during the summer of 1970.

These results induced Maltoni to include workers in VCM and PVC production facilities in his study. Hearing about this, Professor Bartalini, director of the Health Services of the Montedison Company contacted Maltoni and suggested to extend the entire investigation to the experimental study of the biological effects of VCM on animals, with the support of his company. In 1971 Solvay, ICI and Rhône-Progil decided to join this initiative. Supported financially by the 'European Cooperative Group,' formed by those four companies, Maltoni and his team executed between 1971 and 1973 an extensive study of the health effects of VCM. They found that a specific cancer, angiosarcoma of the liver, was the most typical effect of VCM. Not only at the very high doses studied by Viola, but also at exposures of 250 ppm, or even lower. In 1974 a study by Viola confirmed these results.[6]

Maltoni frequently discussed his results with the European Cooperative Group. By September 1972, when there was sufficient hard evidence that VCM was indeed able to induce angiosarcoma, Maltoni's result were also communicated to major American manufacturers of VC and PVC, and in January 1973 also confidentially to the Manufacturing Chemists Association (MCA), who asked an American laboratory to repeat Maltoni's research. After the results had been confirmed, by July 1973 the MCA send part of the information to the responsible government institution, the National Institute of Occupational Safety and Health (NIOSH). That institute took no immediate action though. The 500 ppm threshold value remained in effect, until, early 1974, great unrest broke out among the public. Before that time only very few people, even inside the PVC companies, knew about Viola's and Maltoni's research.[7]

The industry's reaction

Reflecting back on the public exposure of VCM's dangers, an important question arises: How informed was the industry about the dangerous effects of VCM and its potential hazards? When measures to reduce VCM levels in the workplace to a limit of 1 ppm per 8-hour shift (after an initial temporary emergency status where the levels of VCM were reduced from 500 ppm to 50 ppm) started to be taken the industry did not react positively, countering that such a measure would not be feasible.[8] The VCM industry considered 1 ppm a very low limit, arguing that it was technically impossible to reach this value since it would bring grave economic consequences for the plastics industry.[9] Beyond these reasons, the industry defended itself by saying that is was impossible to positively identify the exposure level at which cancer would be induced.[10]

The responses by industry to these accumulated findings of the 1960s were mixed. After acroosteolysis had been discovered at Tavaux, Solvay almost immediately ordered the use of hand shoes among the autoclave cleaners. And B.F. Goodrich, the largest American manufacturer, started a programme of medical screening among the workers, in order to remove 'vulnerable individuals' from reactor cleaning jobs. At that time, however, no fundamental changes were made to the production installations by any of the producers, although some companies improved their cleaning practices, by using, for instance, water jets under high pressures, or organic solvents. But the results were not decisive, because PVC is difficult to dissolve, and therefore manual cleaning practices were not abandoned. Nor did responsible government bodies raise any doubts about the 500 ppm threshold value at that time. This would all change completely after a medical doctor working for Solvay published his results in 1970.[11]

Anxiety about VCM –the reaction of the press, the public and politics

In 2002, the historians Gerald Markowitz and David Rosner published a book regarding the industry's knowledge of the dangerous effects of VCM before the public disclosure of the workers' deaths in the PVC plants, that according to plastic

industry and some American historians is unethical. In their influential book, *Deceit and Denial—The Deadly Politics of Industrial Pollution*, Rosner and Markowitz show that in 1973 the plastic industry had prior knowledge that VCM caused cancer in animals, even at low level exposures. Thus, revealing that American and European plastics industries withheld information regarding one of its major raw materials (VCM) and its potential cancerigenous effect.[12] Given the fact that VCM was the base for the production of hundreds of consumer products, the implications for public health would have been devastating. [13] Subsequently, the industry failed to disclose this information to either the public or to the regulatory agencies.[14]

Parallel to the confidential research going on in Europe and the USA, a left-wing journalist of the *Kölner Stadt-Anzeiger* in Germany, Ulla Jungk, had come into contact with injured workers from the PVC works of Dynamit Nobel at Troisdorf, near Cologne. She interviewed numerous workers on their medical problems and informed the local communist party. During 1973 several articles on the dangers of PVC appeared in the works magazine of communist workers group at Dynamit Nobel, and alarming letters were written to the responsible Bundesarbeitsministerium (Federal Ministry of Labour). The Ministry took the issue seriously and contacted the medical doctors of Dynamit Nobel in the Summer of 1973, but no immediate measures were taken. A few months later this sensitive issue reached the public at large, when in December 1973 an article on the 'Gefährlicher Kunststoff' (dangerous plastic) PVC was published in the influential and widely read weekly *Der Spiegel*.

On 22 January 1974, when the public debates in Germany were approaching the boiling point, a 'publicity bomb' exploded in the USA. That day, the large PVC manufacturer B.F. Goodrich informed the NIOSH, their workers and the public at large that three of its workers had died between September 1971 and December 1973 of angiosarcoma of the liver. Only in December 1973 the two responsible doctors, had related the three deaths to the same cause. The US public authorities, who had been quite passive so far, now responded immediately and organised an 'Informal Fact-Finding Hearing on Possible Hazards of Vinyl Chloride Manufacture and Use' on 15 February 1974 where Maltoni presented his results, which now were published with priority in March. The US Occupational Safety and Health Administration (OSHA) now worked at high speed. Already on 5 April 1974 the OSHA issued an emergence standard which required VCM and PVC producers to reduce exposures to 50 ppm. The temporary standard should be replaced by a permanent one within 6 months. The energetic action of OSHA was no luxury. At about the same time the American VCM industry reported that an additional ten workers had died from angiosarcoma.

The injured image

The whole debate on the carcinogenicity of VCM had important 'side-effects' that would continue to bother the industry for several decades. At the zenith of the public debate on VCM, in 1974 and 1975, headlines like the following appeared for instance in the German press: 'Tod im Plastik' (Death in plastics), and 'Werden wir auf Kunststoffe verzichten müssen?' (Shall we have to live without plastics?). Similar headlines were published elsewhere. In the press, as well as in public debate, not always a clear distinction was made between VCM and PVC, nor between the manufacture of PVC and plastic products made from PVC. As a result, the dark shadow of the VCM episode was cast over the PVC industry or even over the plastics industry in general.[15]

In the case of Germany, Andrea Westermann has analysed how the public debates gradually transformed from a discussion on occupational diseases into debates on the environmental hazards of the PVC industry. In 1976 the discussion, for instance, shifted to the issue of VCM residues in plastic foils for food stuffs. Suddenly VCM, and by implication PVC, was not only a problem for the workers, but for society at large. Later the environmental movement started to attack the waste management of PVC and the chlorine industry as a whole. In the 1970s the PVC industry had acquired a negative image, in some circles at least, and it did not easily get rid of this during the following years.[16]

The controversies and conflicts around PVC bring to the forefront important questions about risk control, scientific reliability and validity. In other words, the PVC case shares features with other controversies in the history of science. Concerning risk evaluation, many of the scientific questions brought forth during the VCM episode are still very controversial and far from being resolved. It has not yet been accurately determined what level of exposure to a carcinogenic may

HOW GREEK SCIENCES PASSED TO EUROPE BY THE ARABS THROUGH AL-ANDALUS AND SICILY

Inas ABBAS
Faculty of Arts, Alexandria University, EGYPT
dr.inas010@hotmail.com

Abstract

It is well-known that the European Renaissance was based on the Classical heritage transmitted to Europe by the Arabs, who did not render it the same as they had taken it.
We are concerned here with an exposition of the nature of that role, which manifested itself in 3 phases: 1) Translating and editing of the Greek text books, both scientific and philosophic. 2) Researching and analyzing through detailed studies of these works, supplementing them with introductions, interpretations, scholia and comments. 3) Application and experimentation of the scientific theories, which thus laid the principles of the scientific method.
As previous studies enumerated the Arabs' contributions in the major fields of sciences, the present survey intends to throw into relief how the Arab scholars exceeded from the theoretical speculations to praxis. By applying this experimental practical method, using instruments and apparatuses developed or invented by them, drawing maps, making tables, they opened new vistas for the appendix sciences either to medicine or mathematics to emerge and grow independently of these major sciences.
Al-Andalus and Sicily, as channels of transmission, provided the institutes and universities in Europe when the translation movement from Arabic started in the 12th century, with all these heritage and studies, where they remained open to fresh investigations and exhaustive researches. They thus paved the way for Europe to proceed into the Renaissance.
To sum up: the growth of knowledge should be looked up as the achievement of all humanity, the active nation who could benefit from the knowledge of the predecessors and then pass it to its successors, with new contributions of its own. In that process, the Arabs played their role.

Centuries separated the Latin west from the Greek thought; during these centuries great modifications had been undertaken as far as sciences were concerned. In the meantime, this Greek heritage called the attention of the Arabs, who devoted themselves from the 8th century onwards to be acquainted with that thought. The Arab Scientists[1] were not content

[1] This term denotes all those who are Arab in origin or lived under Arab rule and wrote their works in Arabic.

to accept the Greek sciences thus obtained, but made them the basis for fresh inquiries. That role played by the Arabs in recovering and reviving that heritage invoked the Latin West to reacquire the full works of the Greek sciences together with the Arab scholarship.

As various previous studies enumerated the Arabs' contributions to the major fields of sciences. The present survey intends to throw into relief how the Arab scholars, when exceeded from the theoretical speculations to praxis by applying experimental and practical method, using instruments and apparatuses developed or invented by them, compiling tables etc., opened new vistas for some appendix and allied sciences, either to medicine or mathematics, to emerge and grow independently of these major sciences.

By following them in their process especially for those appendix and allied sciences, as yet had been given little attention by previous studies, we are concerned here.

If one may follow in headlines the stages, the Greek thought passed at the hands of the Arabs, manifested themselves in 3 phases:

- Firstly, the translating and the editing of the Greek works both philosophic and scientific, which the Arabs entrusted the translators for around 3 centuries (8th to 10th), produced revised versions, helped to the verification of badly copied texts, and also preserved in Arabic versions even works whose Greek originals had been lost.[2]
- Secondly, researching and analysing through detailed studies of the translated Greek works, supplementing them with introduction, interpretations and commentaries, the Arab scholars devoted themselves successively to studies, which become upwards reference works indispensable to comprehend those Greek works.
- Thirdly, applying and experimenting the Greek scientific theories, with careful assessments of the results of the practice, its failures and complications. Thus, laying the principles of the scientific method for the rest of their scientific activities.

Throughout these stages, thus exposed the nature of the role played by the Arabs in this context, one may notice its traces on the scientific works written by the Arabs as well as on the sciences themselves. Among its main traces there are in the first place: how the theoretical speculations undertaken by encyclopaedic scholars, when the classical Greek philosophical corpus, that was understood to include such disciplines as medicine, natural sciences and mathematics, appeared as self-contained and integrated body of knowledge that could explain many varied phenomena by restoring to an all-encompassing philosophical system such as the Aristotelian system. That system was found particularly appealing by scholars, who found in themselves the ability to grasp this kind of interconnectedness of the various kinds of scientific principles. That is why we found such scholars as al-Farabi (ca. 870-950) and his student Avicenna (980-1037) exposing their concepts in encyclopaedic works.

In the second place: how old disciplines treated by refiner scholars; when works of later Greek scientists were found among the translated bulk, which have more specific scientific interests in the spheres of sciences known to the Greeks. Most of those scientists flourished in the Hellenistic era and were related somehow to the scientific school of Alexandria, embodied in Hippocrates (460-360 BC), Herophilos (280-225 BC), and Galen (ca. 129 - ca. 200) in medicine; Heron of Alexandria (ca. 55-68 BC) and Ptolemy (ca. 100-175) in mathematics. These works explored the contents and the dimensions of these sciences, which created among the Arabs a deep desire to recover and deploy them with remarks and refinements, like what Thabit ben Qurra (901) did in an abstract of Ptolemy's Almagest to make it readable, and also make it verifiable through a second book entitled *Introduction to Almagest*[3], updating the text through emendations.

In the third place: how new disciplines emerged by true scholars, whose activities included most and foremost a process of reassessment of the Greek scientific theories by revising the shortcomings resulted by time; and went further than that by creating new scientific disciplines; as was the case with the sphere of applied mathematics from which emerge such disciplines known as exact sciences like Algebra and Trigonometry and their applications on disciplines like astronomy and astrology, which we will later discuss in detail. For the moment we have to refer to scholars of these sciences who tended to express their thoughts in works dedicated to a particular kind of sciences rather than in encyclopaedic works, like Al-Khawarizmi (fl. 825) in his books on "Arithmetic" and "Algebra and Opposition".

Finally in the fourth place: how the scope of the known disciplines were enlarged and tended to specialization by experimentalists and practitioners; when the dependence on well-made apparatuses meant that theory and practice were brought together, but even made practice a more natural part of science itself. By that scientific method, those scholars

[2] For the translation movement and its achievements see: De Lacy O'leary, How Greek Science passed to the Arabs, London, 1949, pp. 155-175.

[3] Ibn al-Qifti, *Tarikh al-Hukama* (*History of the wise*), ed. Julius Libert, Leipzig, 1903, pp. 111-112.

increased the range of mathematization, not only by developing new disciplines, but also by attacking different questions through a quantitative approach. Whereas Archimedes (285-211 BC) and Hero of Alexandria were avoiding discussing openly the applications for their inventions, major Arab scientific figures such as al-Battani (fl. 870) were also expert-makers of instruments which enhanced their powers of observation and calculation, thus widening the scope of the science of astronomy into mathematical astronomy with its applications on daily-life needs.

In the other sphere of science, if the grand characteristic of the Hippocratic medicine was that he advocated the clinical observation, by which alone success in medicine was possible. This great trait in his system, together with the development of the anatomical school at the hands of Herophilos and Galen, absorbed by the Arabs, led to a further advance in the scope of medical science. Thus, nothing more obvious can be noticed than their insistence on the investigations of causes which required the knowledge of physiological and pathological processes, both in general and in the details of particular cases, as recommended by al-Rhazi, (d. 923) and adopted by later Arab scholars of medicine.

Such traces and the like we intend to follow up in detail. But we have to point out briefly how the echoes of the translation movement, together with the scientific studies based on it, were rapidly and widely circulating all over the Arab world among those who were interested, so that the Arab scholars on the western part in North Africa, Sicily and al-Andalus were provided regularly with the most recent translated editions, together with every work in all kinds of knowledge once appear in the East, either through individual acquisitions or by efforts of the authorities,[4] so as to have enough opportunity to follow the scientific activities, and also to take part in them. Thus it is not surprising to find how their writings reflect their views on every scientific issue raised by their counterparts in the East.

Throughout the bulk of the Greek works and the studies made upon them by the Arabs, remarkable points can be investigated in order to point out how the Arabs were dealing with this scientific heritage. We can deduce from some hints to what extent did the Greeks apply the principles of the scientific method known to them, and how far these principles were adopted by the Arabs; and also the impact of their applications on the scope of both the medical and the mathematical sciences, which we are concerned with here.

Nothing more obvious than finding a testimony by the very words of a Greek scholar himself in a letter written to one of his colleagues, in which Archimedes himself said *"I thought fit to write out for you and explain in detail in the same book the peculiarity of a certain method, by which it will be possible for you to get a start to enable you to investigate some of the problems in mathematics by means of mechanics. This procedure is, I am persuaded, no less useful even for the proof of the theorems themselves; for certain things first became clear to me by a mechanical method, although they had to be demonstrated by geometry afterwards because their investigation by this method fell short of demonstration… I think it necessary to expound the method… because I am persuaded that it will be of no little service to mathematics; for I suppose that some of my contemporaries or successors, once the method is established, will through it discover other theorems, which have not yet occurred to me"*.[5]

And according to a commentary by Ptolemy in his *Syntaxis* (pub. ca. 150) on Hipparchus's (fl. 146-126 BC) works on the method used to record the positions for the fixed stars, he said that *"Hipparchus, because he did not yet have in his possession such a groundwork of resources in the form of accurate observations, although he investigated the theories of the sun and moon, and to the best of his ability, demonstrated with every means at his command that they are represented by uniform circular motions, did not even make a beginning in establishing theories for the five planets. All that he did was to make a compilation of the planetary observations arranged in a more useful way, and to show by means of this that the phenomena were not in agreement with the hypotheses of the astronomers of that time"*.[6]

A similar testimony cited by Galen taken from the physician Erasistratus' (280-225 BC) work on the nature of scientific research, he said "*those who are completely unused to inquiry are, in their first attempts, blinded and dazed in their understanding and straightway leave off the inquiry from mental fatigue. But the man who is used to inquiry tries every opening as he conducts his search and turns in every direction… directing his attention to one idea after another that is germane to what is being investigated, he presses on until he arrives at his goal"*.[7]

There is also another citation of the physician Herakleides (75-20 BC) who wrote on Hippocratic exegesis, on a kind of exterior therapy for a reduction of dislocation of the thigh. He recommends that *"one ought not to judge the affair by theory, since it's useful but not completely required to investigate this"*.[8]

[6] *Idem*, p. 77.

[7] *Idem*, p. 301.

[8] *Idem*, P. 308.

Dioscorides (fl. 50-70) also declared his method in the preface of his pharmacy-book, *Materia Medica* saying *"I now encourage you, and any who may chance upon my book, not to look at my verbal facility but at my careful practical experience. For I have exercised the greatest precision in getting to know most of my subject through direct observation, and in checking what was universally accepted in the written records"*.[9]

While Galen himself wrote in his book on "the sects" –the schools of medicine– (ca. 166), suggesting this book ought to be among the first to be read. He explained the method of the empiricists, *"who claim that the art* [medicine] *comes about in the following way. One has observed many affections in people. It is this kind of experience which has contributed most to their art. When they find out that for the most part, it has the same effect in the case of the same diseases, then they call such a memory a 'theorem' and think that it already is trustworthy and forms part of the art. But when many such theorems had been accumulated by them, the whole accumulation was the art of medicine, and the person who had accumulated the theorems was a doctor, such an accumulation came to be called by then 'autopsy', being a certain kind of memory of what is perceived to happen many times in the same way"*.[10] He also recommends observation and dissection when he wrote about the anatomical procedures (ca. 170) saying: *"Make it your serious endeavour not only to learn precisely from books the form of each bone, but also to examine assiduously with your own eyes the human bones themselves"*.[11]

All these citations allude that the Greeks used inquiry, applying observation and practice, but only for the sake of proving the theory. They managed to make all their experience fit in with the theoretical system; they had no reason to doubt the truth of the theories and the conceptions on which the system was based. But tending to observation and practices as a method and a procedure to find solutions or for the application of the theory, that was the method adopted by the Arabs.

The Arab medical thought knows that there are fundamentals in medicine that must not be proved by logic and reasons,[12] as had been realized by Avicenna. But physicians have to start by studying the theory of medicine and to reason correctly. Then, incline to careful enquiry about all relevant symptoms (that is history and medicine). Next, consider prognosis and different diagnosis. And finally, the proper treatment was suggested with careful assessment of the results of the treatment, according to the recommendations of al-Rhazi.

This represents the characteristic contributions of the Arab physicians to medical evaluation. And decide the relation between Greek and Arab medicine, which is best known in the attitude of the clinicians, who often agree with Hippocrates and Galen when their teachings are in accordance with their own experiences.[13] But they differ with them, often very energetically, when it are not; at times they would suspend their judgment until experience indicated whether they were right or wrong. In fact there are some indications in the style of Arab writings which show irritation at the limitations imposed on medicine by philosophical speculation. So examples of their independence are common in their writings when they stated experimental technique.

All these characteristics can be noticed throughout the enormous library of works, encyclopaedias, texts on specialties and guides to medical practice, produced by the Arab scholars, which suffice here to refer to the writing of al-Zahrawi (known as Abulcasis, d. 1013) and Ibn Zuhr (Avenzoar, d. 1162).

Among other medical development was the growing critical examination of the Greek medical writings, specially the works of Galen, expressed in a genre of writings entitled with "Shukuk" (doubts), such as what had been written by Rhazi and later by Averroes (d. 1198). This critical and independent tendency enabled them to add significantly to the knowledge of medicine from the 11th century and throughout the 12th century, widening the scope of the science studying epidemics, advancing the knowledge of anatomy and physiology. Believing medicine to be the art of removing impediments to the normal functioning of nature, they extended their concepts to the study of psychotherapy, when they perceived a close connection between emotional and physical states.[14] Considering the importance of remedies, depending on field-trained herbalists and highly-trained pharmacist-authors, pharmacy first emerged as an independent profession in Islamic land during the late 8th century to reach its zenith in the 13th century, through the greatest Arab text –dealing with medicinal botany– of Ibn al-Baitar (d. 1248).[15]

If we turn to the sphere of mathematics, it will be noticed that the Greeks showed interest in number theory, numerical relationships and the arithmetical operations. In addition to geometry, descended from the principles set forth by Euclid (285 BC), and the problems in constructing interrelated geometrical figures, the character of the mathematical point,

line and space was given intense study in a manner both mathematical and philosophical.[16] And beyond Euclid's definitions great strides were made in theoretical works. The Arab mathematicians devoted considerable time and effort to proving Euclid's postulates, which stimulated them successively to arrive at alternate proofs including proofs of non-Euclidean theorems.[17]

The most remarkable thing is that practical application was never long over-looked. The arithmetic of daily life was essential in everything. Fundamental mathematical principles and definitions, Greek in origin, were clarified in such a way as to increase public understanding of numerical relationships and promote efficiency in all kinds of computation, since such intentions had provoked a mathematician like al-Khawarizmi to produce his works.

Moreover, the beginnings of analytical methods and the foundations of trigonometry by the Greeks have indeed a continuous history of progress when they were handed on to the Arabs.[18]

This can be best shown in some of the exact sciences like astronomy, cosmology, astrology, mechanics, which all had a strong mathematical component. In the early centuries of classical Greece the boundary between cosmology and astronomy was unclear. One Greek savant after another took his own particular look at the heavenly spheres. The Greek philosophers refined the mechanisms of movement within the Greek cosmos of spheres.[19] The Hellenistic astronomers looked at things differently, to a different nature of the earth and the heavens, once a version of Ptolemy's *Syntaxis*, better known as *Almagest*, was produced.[20]

All Arab astronomers accepted Ptolemy's theories as the definitive mathematical model of the heavens with the sun and planets. But by the 11th century astronomy was flourishing in al-Andalus, when Ptolemaic astronomy began to be questioned.[21] In the sphere of theoretical astronomy, the Ptolemaic planetary system was generally accepted, but in the 13th century Arab astronomers eventually came to object in particular to the way his epicyclical motions violated the uniformity of motion, and reached its zenith through hard attempts to come to a new kind of astronomy in which theory and observable fact could be reconciled without having to accommodate noticeable discrepancies. As exemplified in the works of Maslama al-Magiti (d. 1008) and his disciples.[22]

As a result of that, a branch of astronomy that the Arabs termed ilm al-Miqat (the science of time-keeping) emerged as an observational astronomy. In this sphere a great effort was done by increasing need for precision.

Astrology, too, was one of the old disciplines which in the Middle Ages is considered to be irrational and superstitious according to one of its distinct aspects, while the other aspect implies a scientific study of the physical influences of the heavens on earth, that makes it regarded as a science. This understanding of astrology was backed up by a wealth of scientific evidences consistent with the premises of astronomy and other sciences as Ptolemy did in his book *Tetrabiblos*, which became a basic text. Through the Arab enhancements in mathematical calculation, and their increasingly sophisticated methods of astronomical inquiry and analysis, such an evaluation, it offered the possibility that the natural world and scientific knowledge might be put to practical use to benefit humankind. With mathematical approach an attempt is made to combine theoretical knowledge with practical results. Considering the physical effects of the heavenly bodies on the earth, the Arab astrologers study their effects on weather, climate, illness, and human and animal behaviour. This evolution renders astrology more reliable, and is preserved as a science for its common utility; by the 10th century a tradition was represented by a host of Arabic texts devoted to "anw'a" as being concerned with the utility of the rising and setting of constellations for agricultural purposes, and for the general purposes of daily life. Yet, there is a tendency to insist upon the native Arabic background of that kind of knowledge.[23]

In the light of all these traces, which manifest the stages taken by the Arabs in dealing with the Greek sciences and the manner they rendered them to their successors, if we have to say a word about the transmission of the Greco-Arabic learning, whose stages and personages have already been known,[24] we can only refer here to some of its consequences:

first of all, the recovery of classical sciences; secondly, the great interest in Arabic sciences and the development of scholasticism, a distinctive form of analysis, which presents pro and con arguments on carefully defined questions. Scholasticism had its origins in the speculative atmosphere of the 12th-century Renaissance, but soon became the basic method of intellectual argument in the universities of the 12th century and later centuries. These factors made medical science a vital and ever-evolving enterprise.

Conclusion

As the Arabs aroused the interest of the Latins in classical studies, scientific or philosophic, reference has been made to the trend towards the study of the languages of that Greco-Arabic tradition. This interest was not confined to the 12th and 13th centuries, but the movement extended to the 15th and 16th centuries and linked the Middle Ages with early Modern, and enriched the Renaissance with the ancient heritage.

In this brief overview, we pointed out the stages the Greek tradition passed through in the hands of the Arabs, through which it received an evaluating assessments, from the refinements of the perceived mistakes to the modifications that changed its parameters as a result of raising questions, and of increasing need for precision; some disciplines received transformations, others witnessed great overhauls. New disciplines emerged and were given strong pushes to its progress by the Arab scientists who pursued empirical research and its applications, and explored the utilitarian benefits of scientific investigations. Thus the scientific method, that the Arabs adopted, had specific influences on individual branches of sciences. Nevertheless they often show understanding to the different branches of sciences as having both theoretical and practical sides. This prevailed in the tradition they produced, which raise several problems and expose a variety of issues to research and analysis, and aroused the intellectual questioning to be promoted in the universities of the Latin West.

NATURAL PHILOSOPHY AND RELIGION IN BYZANTIUM: DIALOGUE OR CONFLICT?

Manolis KARTSONAKIS
European Culture Studies, School of Humanities, Hellenic Open University, GREECE
mankar@tutors.eap.gr; mankar@sch.gr

Abstract

The work attempts to record the study and the evaluation of the interpretative approaches of Byzantine scholars for natural processes. These interpretations can focus certain views of the questioning which was present among the scholars in Byzantine territories from the 9th to the 14th century.
The varied interpretations for the natural processes which were derived at that period do not reflect only the aspects of their supporters but indicate the influences of the clergy as well and the apprehension of the ancient Greek conceptions within Byzantine scholars.
The views of the clergymen have special interest and importance because during the period we study Orthodox Church was transforming its attitudes towards the study of the Aristotelian corpus, from polemics to reserved acceptance.

Clarifications

The 9th century can be considered as a turning point in the history of philosophical and scientific thought in the Byzantine Empire. On one hand, that century was just after the Late Antiquity and the subsequent Dark Ages and, on the other hand, marked the beginning of the so-called *Byzantine enlightenment*. The 14th century indicates the terminating point of the Empire as it gradually collapsed and was finally conquered by the Ottomans during the 15th century[1].

Some criteria for the selection of the presented phenomena are: the frequency of the records found in the works of various Byzantine scholars, the theological initiatives and outcomes of them and the conjunction between Christian and Hellenic conceptions achieved by the scholars. The preference on them indicates the hassle between the followers of the Aristotelian tradition which was *the only* scientific method at that time –if we may use this term– and the supporters of metaphysical explanations. In other words: it indicates the conflict between rational interpretations and spiritual justifications for the natural processes which was present during medieval period.

[1] Paul Lemerle, *Le premier Humanisme byzantine, Notes at remarques sur enseignement et culture à Byzance des origins au Xe siècle*, Paris 1971, p. 253.

The background

The main figure in history of ancient sciences is undoubtedly Aristotle. He set up a scientific method trying to interpret natural processes and establish a complete qualitative, interpretative method for almost everything which could be approached by human senses. Due to its completeness, the Aristotelian method and interpretation of the phenomena inspired a lot of scholars during the ancient and medieval period and created an interpretative tradition which was active and stood until the Renaissance, when the Copernican revolution and Galilean inventions and innovations necessitated the change *Du monde de "l'a peu pres" a l' univers de la precision*" (=*moving from the Cosmos of 'approximately' towards the exact universe*) if we use the old phrase by Alexandre Koyre.

Aristotelian cosmology was the main method of interpreting the natural phenomena in the Byzantine Empire. The reasons for it were not only its completeness but also its correspondence with the Church's principles for the cosmic view. Thus Aristotelian theory remained in the mainstream of the philosophical thought of Byzantine scholars for almost the whole duration of the Empire despite some problems which occurred in the beginning by the new religion and the biblical tradition[2].

After the 9th century major theological conflicts had been solved, and a mutual understanding between the Christian Church and Aristotelians led to the formation of a new cosmology which tried to include principles from both traditions.

The main difference between these two traditions had remained the acceptance of eternity of the Cosmos from the Aristotelian philosophy and the rejection of it from the Christian theology. But this difference in view was put aside by Byzantine scholars, although they mention this difference in their works and they follow the basic principles of the Aristotelian philosophy trying to comprehend Nature or interpret observed phenomena.

Sometimes, they even put in their works exactly the same words that Aristotle had used in his works. For example if we look at the definition of space proposed by Symeon Seth (a scholar who lived in the 11th century, studied most of the corpus of ancient greek philosophy and presented their views to the Byzantine audience) in his *Synopsis ton Fysikon (Conspectus of the Physics)* written sometime after 1058[3], we see that he defines space as "the termination of the container which contains the containment[4]".

Also, if we turn at Nikephoros Blemmydes, a distinguished scholar who lived 150 years later than Seth in the exiled capital of the Byzantine Empire at Nicaea in Asia Minor (1197-1278) –he is contemporary with Thomas Aquinas– we see that in his *Epitomi Fysikis (Summary of Physics)* which was written after 1258 referring to space he uses the same Aristotelian words as Seth did 200 years earlier: Space is "the termination [end] of the container which contains the containment"[5].

But there is a great difference between these 2 scholars' words though they sound to be the same. This difference has to do with the period these 2 scholars lived. Seth lived in an era where the concepts *Greek* and *Christian* had not yet combined into a single meaning as they later did. So, although he seemed to accept the Christian principles for Nature and Cosmos and had written his *Synopsis ton Fysikon* in the Greek language, on the other hand he referred to the Greeks as pagans and non-Christians[6].

On the other hand, things were easier for Blemmydes, as he lived during an era where the Byzantine Empire had lost its capital, conquered by the Crusaders of the 4th Crusade, and Byzantines, trying to overcome this shocking situation, sought for a new identity looking westwards, to Greece and its glorious ancient times.

---

[2] Nicephoros Gregoras, a distinguished scholar with theological studies and knowledge on Greek philosophy (13th century), proclaimed Aristotle as a source of wisdom. See Nicephoros Gregoras, *Historia Romana*, 3, p.256.

[3] The text was written 200 years before the major translations of the Greek texts into Latin, during a period that Seth's ancient sources were not spread in the West. The work of Seth has been edited by A. Delatte together with another work of Seth (the astronomical essay *On the Need of the Heavenly Bodies*) in the volume *Anecdota Atheniensia et Alia (tome II) textes Grecs Relatifs a l'Histoire des Sciences,* Liege 1939, p. 16-120. My references will be to Delatte's edition. Seth mentioned in the chapter on the eclipses that "here, during Comnenus' reign the whole sun was covered as we have personally observed there" (*Summary of Physics, Anecdota Atheniensia*…, p. 53). That eclipse should be a total solar eclipse visible from Egypt where he was during that period. Our enquiry has found out that during that particular period two eclipses had occurred. The one mentioned by Seth should be the one that took place on 25th February 1058. It started at 1:36 pm at South America and by 2:50 pm the shade covered the whole of Egypt. See also, Manolis Kartsonakis, "The *Synopsis ton Fysikon* of Symeon Seth", in G.N.Vlahakis – E.Nicolaides (eds.), *Byzantium – Venice – Modern Hellenism*, Athens 2004, p. 129-137 (in Greek).

[4] *Anecdota Atheniensia*…, p.64.

[5] Nikephoros Blemmydes's *Epitomi Fysikis* has been edited by J.P.Migne at his *Patrologia Graeca,* Paris 1857-1866, vol.142. The definition about space is at *PG 142*, col. 1100B and at col. 1104D.

[6] At this point we are quoting his words for the Chinese people: "… The Chinese people live at the eastern part of the earth. All of them are ***Greek*** in their faith…". *Anecdota Atheniensia…..,*p.23.

The phenomena and its interpretations

Rain and hail.

We have interpretations proposed by Michael Psellus, the distinguished scholar and nobleman who lived in 1018-1078, his contemporary Symeon Seth and Nikephoros Blemmydes. Psellus interpreted rain and hail as the result of gathering clouds occurred during wintertime, when the sun's influence on earth is less strong[7]. Seth says that it is created by frozen raindrops before they reach the surface of the earth. He also mentions that, if this procedure takes place high in the sky, away from the surface of the earth, then the created hail becomes spherical as it is fallen onto the earth (because of the friction of the air), otherwise –if hail is created closer to earth's surface– each particle of hail remains with edges in different shapes[8].

On the same subject, Blemmydes gives us a more detailed description of the creation of rain indicating that rain is created by the uprising vapor from the earth's surface. For Blemmydes, rain –being a variable quantity of Nature– is created in the sub-lunar part of the Cosmos. It becomes liquefied and frozen due to meteorological reasons and falls again onto earth as hail, rain or snow[9].

A very interesting point in Blemmydes' interpretation of this phenomenon is the reference of an ancient Greek method of interpreting natural processes called antiperistasis. This method was initially introduced by Plato at *Timaeus* under the name *periosis*[10] and was used by followers of Aristotle as a method of violent motions' explanation. The term *antiperistasis* (or *periosis*, if we follow the platonic terminology) describes the transposition of one part of air from the front side of a moving body towards the back.

The acceptance or the rejection of antiperistasis from scholars can be considered as an indication of the way they treated the existence of vacuum: Antiperistasis, as an interpreting theory of natural processes, was easily accepted for the devotees of *horror vacui,* while the supporters of the possibility of vacuum's existence could not accept it as sufficient because the main concern of this theory was to impede the appearance of a void space[11].

Earthquakes.

On earthquakes, we have several references indicated by Byzantine scholars as far as this phenomenon is very dreadful and thundering. If we focus on this phenomenon we will see a conflict that was present in the societies during the medieval centuries: On one hand we have the attempts for logical interpretations, and on the other hand we have metaphysical beliefs and superstitions for them.

We have early references for earthquakes that happened in Antioch in the 9th century, mentioned by Georgios Monahos at his *Chronikon* (written in 813-842)[12]; at the reign of Constantinus X Dukas (reigned in 1059–1067) mentioned by Michael Attaliates –a notable chronographer and historian of the 11th century– in his *Historia*[13]; in 1116-17 mentioned by Anna Comnena (1083-1153) in her historical work *Alexiad,* dedicated to her father's Alexios I Comnenos' reign[14]. The 13th-century historian George Acropolites mentioned two very strong earthquakes (on 11th March 1231 and 16th September 1237)[15], and the historian Georgios Pachymeres also mentioned strong earthquakes in 1265, at Dyrahio (present-day Albania) in 1270 and on the 1st June 1296[16].

Psellus, 300 years earlier, had noticed that the cause of earthquakes is the process of the fire which took place underground in the earth and caused dryness. This process creates a dry spirit which moves rapidly upwards and causes an earthquake[17]. His contemporary Seth exposed his explanation based on natural causes. Seth said that when earth is being

heated, steam and vapor have to be arisen. Steam is moist and vapor is warm and can move easily. When the vapor is being haltered in the earth trying to find an exit, it moves the contiguous earth and brings on earthquakes. Earthquakes take place during windless days and strong winds occur afterwards. He also mentions that only once, during Christ's crucifixion, an earthquake took place all over the earth. Otherwise earthquakes are considered to be local phenomena[18].

Blemmydes also continued this way of thinking and believed that earthquakes are created by the warm and dry vapor that exists under the surface of the earth. This vapor is gathered, fills the underground pits and, trying to shift upwards, moves the surrounding area and consequently the earth's surface. Trying to interpret this phenomenon, he agreed that most of the strongest earthquakes occur during windless periods and at nighttime (because most of the nights are windless). If an earthquake occurs during daytime, it is at noon, because noontime is the most windless of all as far as sunrays are stronger and vertical towards earth[19].

On the other hand, there were scholars and clergymen who had considered earthquakes as metaphysical appearances and had connected them with God's Will and Punishment: i.e. Monahos mentioned earthquakes as a sign of God's disagreement for human behavior on certain theological and social issues, Pachymeres seems to accept divine, superhuman origins of earthquakes connecting them either with God's wrath or a warning of bad forthcomings[20]. Nikephoros Gregoras, considered them as "God's driven phenomena for people's repentance[21].

Comets.

The various appearances of comets had attracted most of the Byzantine scholars and were mentioned in their essays. Starting from Monahos's *Chronikon,* we are informed that during Emperor's Leon V reign (813-820) there was a comet's appearance[22]. Also, Attaliates recorded a comet's appearance during Constantinus X Dukas' reign (1059-1067) in May 1066 and lasted for 40 days, as he informs us[23]. Anna Comnena in *Alexiad* mentioned that a comet was visible during February and March 1106[24]. Acropolites and Pachymeres indicated comets' appearances during the 13th century, and Gregoras referred to various appearances of comets during the period 1204-1359[25].

Apart from these historical references on comets, we have noticed attempts for interpretation of this phenomenon. Seth proposed that they are created by vapor arisen from the earth. Up in the border between sub-lunar and celestial cosmos this vapor is mixed with cosmic fire and transformed into a comet. According to Seth, people that have seen a comet consider it as a mischievous monster.

Blemmydes also followed this Aristotelian view that they are created by vapor arisen from the earth. But, likewise the case of earthquakes, there were several scholars who had proposed a direct or indirect connection between the appearance of a comet and a bad upcoming event. Even Pachymeres named comets as "a signifier of bad events"[26].

Eclipses.

Another very impressive phenomenon which attracted various scholars had been eclipses, both solar and lunar. We have marked records concerning eclipses since the 9th century, made by Monahos and Emperor Constantinus VII Porfyrogenitos himself (reigned in 913-959). Also, in the 11th century there are records for eclipses made by Psellus, Seth, Attaliates[27] and Anna Comnena[28], during her father Alexios I Comnenus' reign. Blemmydes has mentioned a lunar eclipse which was observed in the evening of 18th May 1258[29], Acropolites indicated a solar eclipse at 1238, Pachymeres and Gregoras as well.

Most of these scholars have referred on them as natural phenomena, and they had understood their origin. Seth, for example, indicated that solar eclipses take place when the moon is intercalated between the sun and the earth. He insisted that solar eclipses take place locally and he referred on the solar eclipse that occurred at 25 February 1058, which was

[27] He referred to a lunar eclipse which took place during Michael's VII Dukas reign (1071-1078).

[28] Her reference is for the total solar eclipse which took place in the morning of 1st August 1087. *Alexiad*, Book 7. Ch.2.

[29] *PG* 142, col. 1265c.

visible at Constantinople as we have mentioned[30]. Also, referring on this phenomenon, he mentioned that eclipses may be total or partial depending on the location of the observer. This particular one was total at Constantinople, but partial at Egypt, where he was at that time.

On lunar eclipses, he opined that they were acted out when the earth was located between the sun and the moon so that the earth's shade can cover the moon. He also mentioned that lunar eclipses are either partial or total too. And he hinted that the earth is spherical because lunar eclipses can be seen only from places where it is nighttime[31]. So, he concluded, it is obvious that at the same time some places have nighttime and some other daytime at the same time.

Blemmydes believed that they are natural phenomena and agreed with Seth about the causes for solar eclipses. He declared that the only eclipse based on metaphysical reasons was the one that occurred during Christ's crucifixion. According to his words, "at that time, the moon motivated by the God's Will moved westwards and covered the Sun for 3 hours"[32].

He also agreed with Seth for lunar eclipses. He described a lunar eclipse that he saw once. We have established that this eclipse would have been the one that took place during the night of 18th May 1258.

Lightning and thunderclaps.

On lightning and thunderclaps, Michael Psellus referred to Aristotle's explanations mentioned in *Meteorologica*, where lightnings are supposed to be created by dry steam arisen from earth to heavens. He also presented a view that thunderclaps have to be considered as results of clouds' motion up in the sky. He also commented on the difference of time that takes place in noticing them. He attributed this difference at the different manufacturing of ears and eyes. So, though lightnings and thunderclaps have the same moment as starting point, we realize them with a slight gap[33].

Seth mentioned that we should not consider them as results of conflicting clouds but as results of warm spirits rushing through clouds[34]. Blemmydes described in details the mechanism of thunderclaps' creation based on the rise of the dry vapor and its thickening in clouds. Later on this thickened vapor has become spirit and is expelled from clouds with noise and this is a thunderclap. As it is smashed, it falls off the clouds colored with the color of fire, and we call this lightning[35].

Conclusions

We will outline briefly our conclusions so that we can spot more accurate on the question set in the title:

1. It seems that there was *a living tradition* in Byzantium concerning issues of Nature. This background was influenced by the corpus of the ancient Greek scientific thought represented by Aristotle himself in his various works and of his commentators' texts of Late Antiquity of the Greek-speaking world.
2. The Church did not fully approve studies on them at the first period of the Byzantine Empire: they represented the Hellenic Cosmos, which was non-Christian. On the other hand, a number of distinguished and ingenious Holy Fathers had undertaken serious efforts in order to compromise ancient Greek principles found in platonic and Aristotelian texts and major Christian principles. So this theoretical process led to mutual understanding from both sides and, as centuries went by, Church's opposition was transformed to a silent acceptance on studies of Greek texts on Nature by Byzantine scholars. All these texts had been archived and preserved not only at Constantinople's libraries, but in various libraries all over the Greek mainland[36], in their original language.
3. Distinguished scholars have recorded various phenomena in their works so that we have very useful historical references on these phenomena. Those scholars were educated officials, noble men and women, statesmen, even educated Emperors! All these records give us a significant view of certain natural

---

[30] See footnote 3.

[34] *Anecdota Atheniensia*…,p. 30.

[35] *PG* 142, col. 1180 -1186.

[36] It is remarkable to mention that, during the first decades of the 13th century, during the Latin occupation of Constantinople, Nicephoros Blemmydes, who had undertaken the role of the tutor of the Crown Prince of the exiled Byzantine Empire Theodore II Lascaris, had traveled at the mainland and insular Greek territories searching for archives for his distinguished student and he had found manuscripts in several libraries. See C.N. Constantinides, *Higher Education in Byzantium in the Thirteenth century (1204-1310)*, Nicosia 1982, p. 7 – 27.

phenomena which either had appeared in the areas of the Byzantine Empire or had happened in former times.

4. Certain scholars had moved one step beyond. Having studied the corpus of Aristotelian Physics –including texts of Aristotle's commentators written during the first centuries AC and the Late Antiquity– they had been inspired by it and they tried to interpret natural phenomena using Aristotelian principles combined with their Christian beliefs. This methodological approach of interpretation took place mainly after the 11th century until the paleologian era, which indicates the final collapse of the Byzantine Empire in 1453. These four last centuries were very fruitful for the philosophical and scientific thought at the declining Empire. During that period, several scholars had contributed significantly to the interpretation of natural phenomena. Especially, efforts undertaken during the 11th century have to be considered as very important because they took place 200 years before the massive translations of the Greek texts into Latin: Psellus and Seth knew what Aristotle had said on Nature whilst contemporary Latin scholars did not have the opportunity to study Aristotelian texts at the same era.
5. Nicephoros Blemmydes has to be considered as a major figure among the medieval scholars, but the interpretative approaches on natural phenomena based on the combination between Aristotelian and Christian principles proposed by him and his followers during the 13th and 14th centuries were not sufficiently spread among the scientific community of that area, as Thomas Aquinas' similar ones did. The reasons for this can be traced on social and nonscientific fields: i) the central location of the scientific evolution was not in the Mediterranean areas, and was moving westwards through the massive oncoming translations of the Greek corpus into Latin; ii) the key role of the Greek language as the mother tongue of the scientific texts was shrinking; and iii) the communication between the Latin and the Byzantine world was lacking under the pressure of the increasing religious and political conflicts[37].

So, Byzantine scholars introduced the methodology of combining Aristotelian and Christian principles independently from similar efforts undertaken in the West.

[37] It is considerable to indicate that Nicephoros Gregoras had achieved to prepare a new calendar which was correcting the irregularities on the calculation of Easter occurred in the Julian calendar. He presented his new calendar in the Court of the Emperor Andronicus II Paleologos at 1324. His work did not have any success on replacing the Julian calendar (250 years before the Gregorian reform of 1578) because the Emperor hesitated to put it in practice as –using the Emperor's words– "it was difficult to persuade foreign leaders to accept this reform". See Nicephoros Gregoras, *Historia Romana*, book 1, p. 367 – 373.

HISTORY OF PHYSICS AS A DIDACTIC TOOL

vtahiri@univlora.edu.al

Abstract

The history of physics provides the students with recognition about the history of human efforts in science. Through this discipline they become familiar with the lives of great scientists and the gradual evolution of ideas. Although there are several exact theories accepted by all, scientific theories are still open to be attacked by new experiments and new ideas. On the other hand, through this discipline, the pupils or students have the opportunity to ask and to be active in practice, to collect historical material in order to establish a museum of physics, or to set up software according to the historical periods of development of science and technology.

As an attempt to find teaching strategies to improve the teaching of science, we should consider the history of science as a teaching tool and as a description of integrated school curricula. The purpose of this article is to treat some of these problems addressed on the Course of History of Physics. This course will reflect the overall development of the main areas of physics, as we know today. It will appear as a clear linear model, and develop the main forms in each area, which will evidence that science is the attempt to give a rational explanation of the laws in nature, more accurate than magical or religious explanations.

People in different countries of the world began to develop science at different times, with different accents. Looking at the history of science as part of the culture to transmit to school can be argued that this emerged as a discipline in itself.

According to our opinion the history of science can be considered as a part of curricula and will be appropriate to observe possible results of the introduction of historical arguments.

- The first result is the transmission of information on the historical development of knowledge, with the relation science-technology-society.

- The second result is the best acquisition of physics through analyzing the physical ideas from a historical viewpoint.

- The third result is engagement of students in practical activities, projects, papers and assignments to build a museum of history of physics. It can lead to a greater integration between the human and scientific area through an interpretation of the history that realizes the ratios; man-environment, human-nature related with the development of technology through integrated analysis in social and economic form.

Introduction

Man has made efforts to recognize the world in which he has lived, not instantly and not available in definitive form. For example, recognition of the physics laws, which already are known by all the science with the name of "Newton's Laws" needed a long time for recognition: some thousands of years. It also needed two and a half centuries understanding the limits of these laws: they are not universal, and should be specified for objects that move with very large speed, comparable with light speed, and for very small objects (particles).

Humankind has passed and will always pass through a long and difficult way, from acknowledge to recognition, consistently replacing on this path the incomplete and imperfect knowledge with the more complete and more sophisticated knowledge. In a few words, knowledge has historical character, science has history.

Essentially, any researcher should be informed on what was done before him about the problem that is being studied and should evaluate critically the results obtained from his predecessors. Nothing is born in an empty space. Each new generation starts at the place where the previous has stopped and gives its obtained results to the next generation. Without Euclid and Archimedes, we wouldn't have Newton. Without Newton we wouldn't have Einstein and Bohr. The study of the development process of recognition represents the task of a specific science of the history of science. The history of physics is a part of the history of science concerned with the study of the historical development of the physics science.

The main task of the science is to discover the laws that govern each area that it is concerned with. The main task of the history of science refers to finding the laws that govern the development of science. At first sight, it might look like such laws do not exist. The appearance of Archimedes, Newton, Einstein, Planck, could not be predicted; the scientist's thinking and creating cannot be directed. Outwardly, the history of science can be visualized as a result of uncontrolled activity of the particular genius scientists. But it is incontestable that the science is the product of human activity and by far the most complex, intellectual, cognitive and creative activity. From this point of view, the development of science occurs in historical, economic and cultural conditions, which play an important determining role. These conditions represent the real basis of human activity, including the basis of their spiritual activities. In this way, the start and development of science is possible in a specific level of economic development. The start and the development of science are characterized by the production. Especially, this role in developing of science is clearly evident in today's historic stage, where the development of spacecraft and plasma physics, etc., requires a staff and super-colossal qualified tools, namely a powerful and developed education system. It is understood that a strong economy is required to ensure all conditions for the developing of science today. Economic conditions create the necessary bases for all life of society, including science. But other factors play a crucial role for the existence of these bases; so, for any researcher, the internal factors are determining: the status of scientific knowledge, the actuality of the problem, interests and personal skills, etc.

Science not only gains independence, but influences on the social production, stimulates and accelerates the development of the productive forces, being themselves transformed into the productive force. We note that the correlation of science and production has also an historical character, and it is developed with the development of the science production.

Through what we have presented, it is clearly apparent that the task of the study of science development legality, including physics, has a completely defined meaning and a great scientific value. Today, when science itself is the development factor of society, especially this task becomes prevailing. The history of science plays a principal role in the theory of recognition. Here, it consists in the fundamental scientific value of the history of science. Also, the history of science has methodological and didactic value. Quite often the historical way of the recognition of science is the most effective. Therefore, for teachers of physics, recognition of the history of physics is necessary, by providing them methodically and scientifically. The history of science educates the love and respect for science and scientists, helps fighting against dogmatism and formalism and wakes up scientific cooperation between educated people.

Historical aspects

There is much debate and discussions on the role of science history in didactics of physics. The opinions in this debate are contradictory. Some underestimate the role of the history of physics with the following argument: "Since a theory tends asymptotically towards an instant stable, logically independent, then why should I get lost in the labyrinth of history?" Others are skeptical: how can we achieve within a short time to learn everything about the history of science? A significant part (including the authors of this paper) are optimistic, seeing the history of science as a part of intellectual culture that should be taught in schools as a subject in itself. That's for the fact that the history of science is the arena for continued discussion of scientific and philosophical problems. In the learning process we can see how science is extended and deepened, introducing its own sphere of new objectives for science. So, discovering new properties and ratios, we can see how the old concepts are overturned and how recent concepts are affirmed and, based on them, the new methods, theories, and recognition procedures are created.

Considering that the history of science should be treated as an independent part of curricula, we find the worth opportunities to observe the presentation of historical arguments, limited to placing emphasis on the didactic values of the history of science. On the other hand, this independence of the history of physics as an independent subject provides us the opportunity for transmission of information in the conceptual development of science, being limited in their methodological valence.

Three important benefits are derived from the above arguments, which are closely related to a particular science discipline of physics. Firstly, a better understanding of concepts can be obtained through their treatment in a historical point of view. Historical perspective based on the source materials of scientists, correspondences between them, debates or discussions in seminars, scientific conferences and congresses, has a huge significance for two reasons: to show how the idea or theory is born, confirmed and developed facing the opinions and viewpoints, pros and cons, with all scientists in a specific constellation.

Secondly, to create good perceptions among students, that physical science is not a definitive ready product of one or several of the brightest minds, but a human real effort of several generations of physicists. Only the literature of the history can draw this picture, which also serves to convince students how much sweat, effort and desire is needed to confirm an idea, hypothesis or new scientific theory, when even the brightest, greatest minds at a period of time are often confused and accept new scientific ideas with difficulties, but before the experimental facts “force” even the stubborn conservative people to renounce old perceptions. This is the way of recognition of the scientific truth, which is always relative, and also is developed and perfected.

Another conclusion, which underlines the methodological aspect, means the whole conditions and principles which the concrete methods of study and description of physical phenomena (dynamical and statistical methods of description of physical condition) are based on. Relying on them, physical doctrines (classical and quantum) can be built, and the application limits of theories can be defined. The methodologies of physics in this sense may undergo substantial changes not only replacing a philosophical base of physics to another, but even when changes occurring in science do not doubt the philosophical basis of science that supported those changes.

Methodological systematization of the scientific thinking experience and the history of scientific thinking is, of course, not the same as the systematization of knowledge and scientific discipline procedures. In the latter part of the sentence, systematization aims at the realization of a logical and coherent order of scientific thinking in limitations of any known area. Otherwise, the methodological systematization aims at realization of an interdisciplinary relationship based on the scientific thinking experience and his historical carriage from one area of knowledge to another. Since our knowledge is not a priori, but derived from all human experience analysis and generalization, every human insight to the novelty and unexplored area of phenomena, leading to the necessity of the radical revision and the generalization of our fundamental concepts and perceptions, even such as time, space, action, motion, energy, etc.This, of course, doesn’t mean that every new stage of scientific development disclaims everything previous. The using limitations of those concepts and laws which were earlier considered universal are emerged at each new stage and the lawfulness of a more general character are discovered.

The requirements to any new theory is that it becomes increasingly stronger because it not only needs to explain continuously discovered facts, but also to include the special cases of all earlier discovered lawfulness, noting the exact limits of their use. Thus, the classical physics fundamentals are included in the more general laws of relativity and quantum theory, of which they are derived, in conditions when the object speeds are very small compared with the speed of light, whereas the space-time grades of the phenomena and the measures of objects are such that the action to be large compared to the quantum constant.

Conclusions

The treatment of the history of science in its conceptual aspect increases the logical valence of the birth of new ideas. The path toward birth of new ideas is not simple. The novelty is hardly affirmed through a “tough fight” with the older one. Across the unexplored path of new theory, firstly “the track is opened”, the hypothesis or new scientific ideas are postulated, which are not born in a vacuum space and at every man. After this moment the “crisis” is started of existing perceptions or theories which are unable to explain new experimental facts. Already, the role of the scientist appears, his intuition to connect between them two different groups of facts. This connection decides the order and consequently the simplification and perfection of the scientific picture of the world.

The above mentioned conclusions aren’t anything else, except some of the practicable possibilities. So, we find ourselves in front of a wide spectrum of opinions that ranges from a full teaching to a directed teaching in an in-depth manner in an intellectual and cultural sense, which doesn’t require ordinary knowledge of the history and methodology of physics. Based on the training establishment level of teachers, precisely to focus on above mentioned aspects, it may be valid to compare the arguments in a more clear structure in a historical and methodological viewpoint. Devoted to this idea, we have presented the following proposal, which not only serves as structure to the course of history of physics, but as well as laboratory of the history of physics in the recognition aspect.

Abstract

In January, the University of Barcelona opened its Virtual Museum. This experiment is a pioneering one in Spain and a project that began with the aim of publicizing the University's entire heritage to students, researchers, scholars and the general public. The system that has been used is a particularly modern and highly specialized database designed for cataloguing all kinds of museum material. Linked to the program, we have also acquired the version making it possible to display the museum on the Internet.
The museum is currently organized in 11 collections and covers about 300 pieces, a small sample of the university's heritage which we have made available to the public in the form of an online showcase. We are now enriching the Virtual Museum with a second phase which introduces new pieces into the existing collections and also expands the number of collections.
This contribution is devoted to the description of the six scientific collections included in this virtual museum.

Introduction

In January 2010, the University of Barcelona opened its Virtual Museum. This experiment is a pioneering one in Spain and a project that began with the aim of publicizing the University's entire heritage to students, researchers, scholars and the general public.

The system that has been used is a particularly modern and highly specialized database designed for cataloguing all kinds of museum material. Linked to the program, we have also acquired the version making it possible to display the museum on the Internet.

The museum is currently organized in 11 collections and covers about 300 pieces, a small sample of the university's heritage which we have made available to the public in the form of an online showcase. We are now enriching the Virtual Museum with a second phase which introduces new pieces into the existing collections and also expands the number of collections.

This contribution is devoted to the description of the main features of this virtual group of elements and collections belonging to the Heritage of the University of Barcelona.

Eleven collections

Art

Art brings together the artistic and architectural heritage of the UB and features a series of sub-collections including the *Pinacoteca*, a gallery of three hundred paintings, fifty-six of which belong to the Prado Museum.

The Fine Arts Collection

The Fine Arts Collection of contemporary art brings together the work of students and teachers associated with the Faculty of Fine Arts and the former Sant Jordi School of Fine Arts. The collection provides a showcase for the trends and tendencies in Catalan art from the early twentieth century until the present day.

Animal Biodiversity Resource Centre Collection (CRBA)

The historic collection of the Animal Biodiversity Resource Centre (CRBA) contains exhibits of birds and mammals from the *Gabinet d'Història Natural*, which was created in 1847. The CRBA also features numerous specimens of different animal groups in its science collection and in the part of the collection providing a study and teaching resource for UB members.

Pavelló de la República *Library Collection*

The *Pavelló de la República* Library Collection brings together documents from the Centre for International Historical Studies (CEHI) and the Josep M. Figueras Library in one of the country's most important collections on the subjects of the Second Spanish Republic, the Spanish Civil War, exile from Spain and the Regime, and the period of history known as the Transition to Democracy, both in Spain as a whole and in Catalonia.

Mineralogy Collection

The Mineralogy Collection is housed in the Department of Crystallography, Mineralogy and Mineral Deposits. With a total of almost 20,000 mineral samples, 7,000 thin sections and 3,000 polished sections, the collection brings together all internationally recognized mineral species and highlights both their aesthetic and scientific value as part of our international mineral heritage. Finally, the collection is also used in classes by teaching staff in the degrees of Geology and Geological Engineering.

Sabater Pi Collection

The Sabater Pi Collection is housed in the Barcelona Science Park (PCB) and contains the scientific and artistic works of UB emeritus professor Jordi Sabater Pi.

Rare Book and Manuscript Library

Housed in the Historic Building in Plaça de la Universitat, the Rare Books and Manuscripts Library contains historical documents relating to the University of Barcelona dating up to the nineteenth century. On a national level and after the National Library and the *Biblioteca Columbina*, the reserve is the third largest collection of its kind in its collection of incunabula, and, after the National Library, the second largest in terms of its printed material from the sixteenth to eighteenth centuries.

The Herbarium BCN (CeDocBiV)

The Herbarium BCN is supported by the UB's Centre for Research on Plant Biodiversity (CeDocBiV) and contains around 300,000 specimens, mainly from the area of the Catalan Countries (*Països Catalans*) but also from the rest of the Iberian Peninsula, Northern Africa and tropical regions of South America.

Scientific Instruments

Scientific Instruments contains more than 500 exhibits of historical interest and is housed in the Faculties of Biology, Chemistry, Medicine, Pharmacy, Physics, and Psychology and in the School of Nursing. The collection offers the visitor a broad range of examples of instruments used in teaching and research from the eighteenth to the twentieth century.

Faculty of Geology Mineral Collection

The Mineral Collection is housed in the basement of the Faculty of Geology building and contains a broad range of rock, mineral and fossil exhibits used in teaching and research.

Catalan Pharmacy Museum

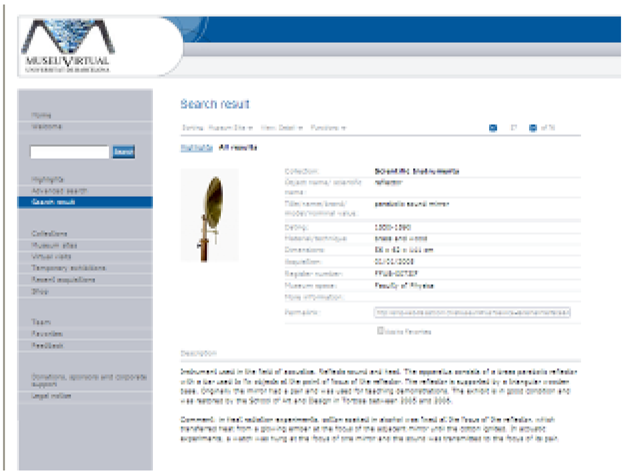
The Catalan Pharmacy Museum gathers together over two thousand objects of different kinds, as well as two emblematic collections: a series of ancient pharmaceutical specialities —the largest collection— and a group of old posters advertising pharmaceutical products.

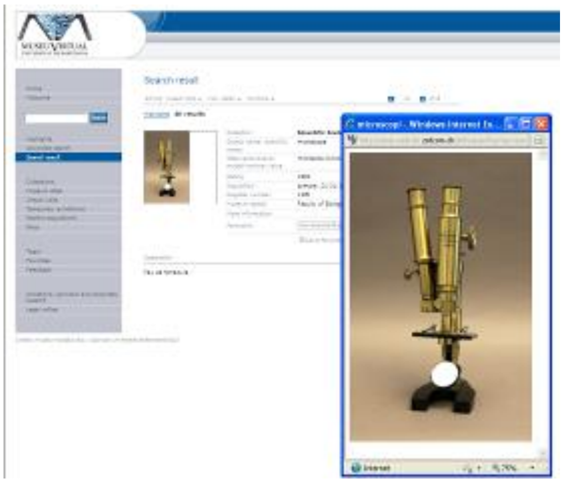
Inside the collections

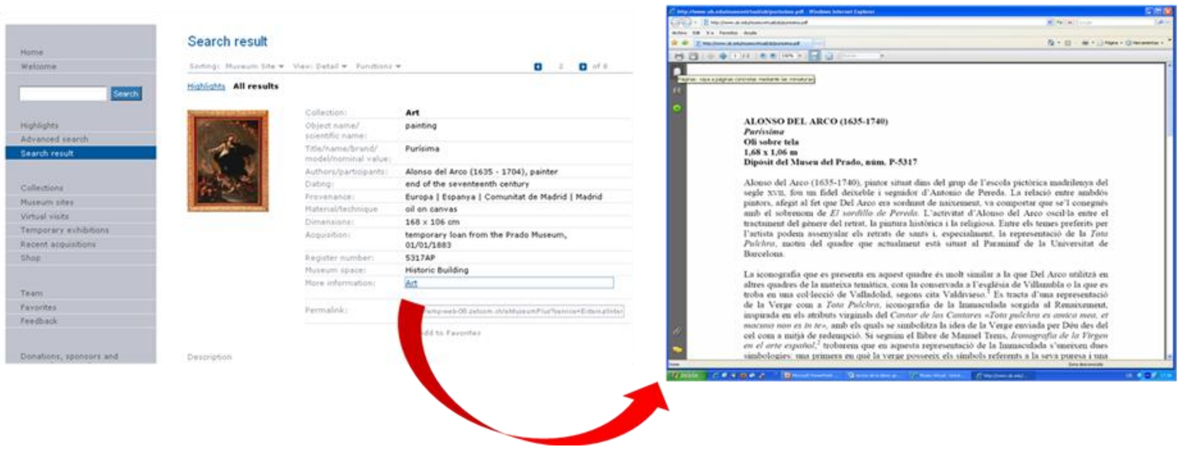
You can have a quick look at any collection by clicking on *Highlights* or you can see the *Complete Collection*. Alternatively you can use the *Advanced search* in order to find some specific item.

By clicking on each item more information should appear, such as the provenance, register number, the title/name/brand/ model, authors/maker, dimensions, materials, and other general information.

It is also possible to broaden the information and see more details by opening attached documents in pdf format. By clicking on each picture an enlarged image is shown.







The Scientific Instruments collection

The section of Scientific instruments exhibits items located in the Faculties of Biology, Chemistry, Medicine, Pharmacy, Physics, and Psychology and in the School of Nursing. At present it contains 76 instruments, offering examples of instruments used in teaching and research from the two last centuries. Among the 22 highlighted instruments there are a complex sectioning microtome, a very early X-ray machine and a magic lantern dated around 1885.

Virtual tours: the Historic Building and the Gaudí Pavilions

At present there are two possible virtual tours. One corresponds to the Historic Building in the centre of the city and the other corresponds to the Gaudi Pavilions, in the North Campus of the city.

The virtual tour of the Historic Building is divided into four main sections: the History of the University of Barcelona; the City; Elies Rogent –the architect of the building; and the Historic Building. Each part is subdivided into several photographs and descriptions providing synchronised information.

Concerning the Gaudí Pavilions, there are three sections: Ceramic and exposed brick; the Garden of Hesperides; and the Iron Dragon, besides information and photographs of several other sections.

More information: News, Temporary exhibitions, Recent acquisitions...

In all these sections all the related news is presented with the relevant information and with the links that allow connection with the original sites.

Conclusions

Since it was inaugurated one year ago, the University of Barcelona Virtual Museum has been steadily consolidating its structure and perfecting the system it uses to exhibit the various collections that comprise our university heritage. We are now enriching the Virtual Museum with a second phase which adds new pieces to the existing collections and also expands the number of collections. To this end, we are preparing the Virtual exhibitions section, which will support the Temporary exhibitions section, where we announce exhibitions organized by the different campuses of the University of Barcelona.
